1847.

TO

JOSEPH HENRY GREEN, F.R.S.
PROFESSOR OF ANATOMY TO THE ROYAL ACADEMY,
AND
SENIOR SURGEON OF ST. THOMAS'S HOSPITAL,

THIS WORK

IS INSCRIBED,

AS A TESTIMONY

TO HIS HIGH PROFESSIONAL AND MORAL WORTH,

AND

WITH CHERISHED REMEMBRANCE OF A WARM AND STEADY FRIENDSHIP,
UNDER MANY TRYING CIRCUMSTANCES,

DURING MORE THAN THREE AND THIRTY YEARS,

BY

HIS AFFECTIONATE FRIEND AND COLLEAGUE,

JOHN F. SOUTH.

Blackheath Park, 1847.

AUTHOR'S PREFACE TO THE FIRST EDITION.

THE object I had in view in the production of the present work was a short and clear description of Surgical Diseases and their Treatment; in which I have endeavoured, as far as possible, to point out the best works both of these and foreign countries. According to the plan of this book, many things are slightly treated of, and many only hinted at, which will be enlarged on in my oral lectures.

I must not be blamed for having omitted Diseases of the Eye and Ear; for Ophthalmic Surgery has attained so great importance as to require a special treatise; and, like many other Teachers, I deliver a separate course of Lectures on Diseases of the Eye and Ear.

Heidelberg, November 1821.

PREFACE TO THE FIFTH EDITION.*

THE short space of time in which a new Edition has become necessary, (although the fourth consisted of above two thousand copies,) and the translations of it which have appeared in seven different languages, are such honourable and pleasing testimonies of the continued favourable reception of this book, that I have, with the greatest diligence, endeavoured to enlarge and improve it, in correspondence with the present state of Surgery. The last six years have been specially fruitful in important events throughout the whole realm of Surgery, and I trust I have not overlooked anything of consequence. To M. PIGNÉ, I must offer my best thanks for the many additions he has made to his French translation.

Heidelberg, June 1839.

---

* Second Edition, Dec., 1825; Third Edition, April, 1828; Fourth Edition, April, 1833.

PREFACE TO THE SIXTH EDITION.

ALTHOUGH from the extremely short space of time which has rendered a sixth edition of this Handbook necessary, very numerous additions and alterations cannot be made, yet I hope, by much improvement, to have increased its utility. May it still continue to merit the favourable reception it has hitherto enjoyed.

CHELIUS.

Heidelberg, *August*, 1843.

TRANSLATOR'S PREFACE.

It is a common practice in the German Medical Schools for the Teacher to publish a Textbook on the subject of which he treats, and, taking this with him into the Class-room, to enlarge upon it, and thus form his lecture. This is the reason why, in the work of Chelius, many things are but slightly noticed, and some only hinted at, which seem worthy of being fully and completely detailed.

Had I confined myself to a mere translation of my original, many important points must have been omitted, and the object for which I undertook the publication of the Handbook could not have been attained. I was therefore obliged to resort to annotations and comments, the result of my own experience and reading, for the purpose of filling up and enlarging the Author's short notices, so as to render them more generally useful both to the student and the practitioner. In doing this I have far exceeded the limits I had originally proposed to myself, but the subject is so important, and fresh matter was so constantly at hand, that my great difficulty has been in restricting my work within its present bounds.

My first object in undertaking this task was to render Surgeons in this country more conversant with foreign practice than they had hitherto been. French Surgery, with its showy, but sometimes too hazardous operations, had indeed been pretty well known among us ever since the peace of 1815, soon after which, medical students, with other British visitors, flocked in crowds to the French capital. But of the Surgery of the German Schools very little had been known in England until within the last few years, no standard German book having appeared in English since the publication of Heister's valuable work a century ago.

Several years since, when I was preparing to deliver Lectures on Surgery at St. Thomas's Hospital, (soon after commencing which, severe illness forced me to resign my appointment,) I was thankful for the great assistance I derived from becoming acquainted with CHELIUS's excellent *Handbuch der Chirurgie;* and as I grew more familiar with the work, it appeared to me that a translation of it would present to my countrymen a fair and satisfactory view of the important services which our German brethren have rendered to Surgery. Still, however, I felt it would be necessary to add notes of my own, for the purpose of explaining and discussing occasional, and sometimes important, differences in the practice of the German and English Schools. In doing this I trust I have fairly stated the arguments on both sides, and shown on what grounds I have decided between them.

I shall be charged, I fear, with having buried my Author beneath a mass of notes and comments. They are indeed numerous, and they might occasionally have been made shorter, had I condensed, in my own words, the opinions of the authors I have cited. To this practice, however, though not uncommon, I am utterly opposed. The meaning of a writer ought to be best set forth in his own words, and if others attempt to convey his meaning briefly, they not unfrequently fail to declare his opinions, or they altogether misrepresent them. I have, therefore, with but few and unimportant exceptions, quoted the statements of authors in their original words. I have also, as far as possible, endeavoured to award to the originators of new modes of practice, their just meed of credit; and if, as may occasionally have happened, I have passed by unnoticed any of the leading Surgical writers of the British Schools, I hope on a future opportunity to repair my seeming inattention.

To Professor CHELIUS, with whom I communicated previously to the commencement of my publication, my best thanks are due, for his kindness in furnishing me with the several parts of his new edition, at the earliest opportunity. I trust he will be gratified with the pains I have taken to place him in a condition to be estimated as he truly deserves to be by British Surgeons, and to make his work a stock book in English Surgical Literature.

I have also to thank many kind friends who have furnished me with information which has been of great use to me, and which I could not otherwise have obtained. But to none am I more deeply indebted than to my able and excellent friend **James Dixon**, Surgeon to the London Ophthalmic Hospital, and lately Demonstrator of Anatomy in St. Thomas's School, for his ready and constant assistance during the whole course of this work; and it is with much pleasure that I take this opportunity of offering my testimony to his high professional talent and private worth.

Before I conclude, it is but justice to my Publisher to acknowledge his liberality in allowing me entirely to control and conduct this work, according to my own views, no less than his readiness in undertaking, solely on my recommendation, the publication of a book, which, although well known and estimated abroad, was almost new to English Surgeons, and could only be brought out, in the manner I desired, at considerable risk and expense. To him, therefore, is due in part the appearance of this *eighth translation* of Chelius's Handbook, since without his assistance it would probably have never seen the light.

I know not whether to consider it a matter of gratulation, that a reprint of my translation has been begun at Philadelphia. Nine numbers have already appeared, without any communication having been made with my publisher, although he had offered to furnish an edition for the American market before the forms were broken up. I must at least feel gratified that my Author's celebrity has reached to the western hemisphere: it will be extended to India, in a way more satisfactory to my publisher, through the munificence of the Directors of the Honourable East India Company.

John F. South.

Blackheath, February, 1847.

ANALYTICAL INDEX.

Abdomen, Wounds of, i. 456; varieties of wounds of the abdomen, i. 456; superficial wounds, i. 456; bruises—symptoms, treatment, and consequences, i. 457; treatment of wounds of the epigastric, internal mammary, or abdominal artery, i. 457; Travers on the effects of injury of the abdomen, i. 457; general treatment of wounds of the abdomen, i. 457; penetrating wounds, i. 457; symptoms, i. 457; Hennen on the escape of the intestines from injury, in penetrating wounds of the abdomen, i. 457; Green's case of fatal penetrating wound of the abdomen, i. 458; treatment of simple wounds of the abdomen, i. 458; Travers on wounds of the abdomen, i. 458; use of sutures in wounds of the abdominal parietes, i. 458; occasional symptoms caused by the use of sutures, i. 458; mode of applying the sutures, i. 458; Graëfe on the application of sutures, and including the peritoneum in the suture, i. 459; treatment of penetrating wounds, i. 459; Hennen on the treatment of penetrating wounds of the abdomen, i. 460; protrusion of the omentum or intestines, i. 460; return of the protruded part, i. 460; enlargement of the wound sometimes necessary to effect the return, i. 460; condition of the protruded intestine a guide to its return, i. 461; if the omentum be inflamed, bruised, and partly disorganized, or gangrenous, it must not be returned, i. 461; Dupuytren objects to the return of the protruded omentum into the abdomen, i. 461; *Wounds of the Intestines*, i. 462; symptoms, i. 462; Travers, Green, Tyrrell, and South's cases of wounded intestines, i. 462; Travers on wounds of the intestines communicating directly with the surface, i. 463; varieties of wounds of the intestines, i. 463; Travers on the varieties of wounds of the intestines, i. 463; difference of opinion as to the treatment of wounded and protruded intestine, i. 463; different kinds of stitches employed, i. 463; Scarpa and Larrey's practice, i. 464; Denans, Béclard, Jobert, Lembert, and Reybard's practice in wounded intestine, i. 464, 465; Shipton's and Travers' experiment, i. 465–7; Else, Benjamin Bell, John Bell, and Hennen, on the use of the suture in wounded intestine, i. 466, 467; objections to the use of stitches in wounded intestine, i. 467; reasons in favour of their use, i. 468; Travers on the objections to returning a wounded intestine, without suture, into the abdomen, i. 468; Travers and Benjamin Bell, on the withdrawal of the suture, after union has taken place, i. 468; Travers' directions for stitching a wounded intestine, i. 468; approval of Lembert's plan, i. 469; Astley Cooper's practice in small wounds of the intestines, i. 469; Dupuytren's modification of Lembert's plan, i. 469: Travers on the reparation by artificial connexion of the divided parts of a wounded intestine, i. 470; treatment of a perfectly divided intestine, one end only being found, i. 470; treatment of wounded intestine, i. 470; treatment of wounded intestine when the fæces escape by the wound, i. 471; Travers and South on the treatment of wounded intestine without fæcular discharge or prolapse, i. 471; Travers on spontaneous reparation in wounded intestine, i. 471; contraction of the intestine sometimes the result of a wound, i. 471; effusion of fæcal matter, blood, or other fluid, constitutes the most dangerous complication of penetrating wounds of the abdomen, i. 471; Travers and Hennen on effusions into the cavity of the abdomen under such circumstances, i. 472; extravasation of the intestinal contents, i. 472; Travers on the impediments to effusion of the intestinal contents, i. 472; symptoms of effusion, i. 473; effusion of blood into the cavity of the abdomen, i. 473; the effused blood is either collected in a circumscribed space, or diffused over the abdomen, i. 473; treatment of extravasation, i. 473; Hennen's case of musket-shot wound of the abdomen, the ball passing afterwards per anum, i. 474.

Abernethy, on severe phlebitis, i. 78; on poultices, i. 85; on opening a cold abscess with a lancet-puncture, or a trocar, i. 90; on incisions in carbuncle, i. 138; on permanent chordee, from the extension of the inflammation to the corpus spongiosum, i. 158; on gonorrhœa virulenta, i. 162; objection to any attempt to check gonorrhœa, i. 169; recommends a soothing practice, i. 169; on lumbar abscess generally connected with carious vertebræ, i. 186; experiments to cause the absorption of the pus, i. 188; treatment of lumbar abscess, i. 189; supported by Astley Cooper and Lawrence, i. 190; on the symptoms of the inflammation which sometimes supervenes after the abscess has been opened, i. 191; paronychia ungualis, i. 192; paronychia tendinosa, i. 193; paronychia osseosa, i. 194; on epinychia, or ulceration, with great thickening at the ends of the fingers, i. 194; on the cure of epinychia, i. 198; case of wounded meningeal artery, i. 301; on a costive state of the system preceding tetanus, i. 378; on the treatment of simple fracture of the skull with depression, without the trephine, i. 392; on puncturing the dura mater, to evacuate the effused blood, i. 407; only employs the trepan in injuries of the head, when secondary symptoms of irritation and pressure require it, i. 412; on the use of a broad-chest bandage in emphysema, i. 452; mode of treatment of wounded joints, i. 490; commended by South, i. 490; on the question of immediate amputation in compound fractures, i. 518; on symptomatic fever, i. 521; the bracket splint, i. 523, 524; denies the possibility of simple dislocation of the spine, i. 534; on the operation of trepanning the spine, i. 541; on pseudo-syphilis, i. 651; on the means of distinguishing between true and false syphilis, i. 651; on the occasional spontaneous healing of chancre, i. 655; on the effects produced by the ligature on the arterial coats, ii. 219; on the application of two ligatures, and the division of the artery between them, ii. 222; case of ligature of the internal carotid, on account of a wound, ii. 233; case of ligature of the external iliac in the groin, ii. 258; on the ligature of the external iliac, ii. 261; on compression in the treatment of teleangiectasy, ii. 282; on passing the bougie in stricture of the urethra, ii. 359; on the use of metallic bougies, ii. 359; on hæmorrhage from the urethra after passing the bougie, ii. 365; on puncturing spina bifida ii. 468; on the division of tumours, ii. 647; on fungus hæmatodes, ii. 721; on the treatment of traumatic phlebitis, ii. 863; on the complete section of the nervous twig in cases of wound of a nerve-branch in bleeding, ii. 863; case of division of a nerve wounded in blood-letting, ii. 887; case of excision of part of the digital nerve, ii. 887; mode of amputating at the hip-joint, by the circular cut, ii. 934.

ABSCESS, i. 34, 36; formation of the walls of, and the circumscription of the pus, i. 36; the walls are secreting and absorbing surfaces, i. 36; metastatic abscesses, i. 36; Travers on the lining membrane of an abscess, i. 38; Hunter and Travers on the circumstances which determine an abscess to the surface, i. 38; cold or lymph abscess i. 45; abscess of congestion, i. 45; symptoms of cold abscess, i. 45; Mr. South's case of cold abscess, i. 45; Dr. Rigby on puerperal abscess, following contagious or adynamic puerperal fever, i. 47; when an abscess is ripe, it either opens of itself, or it must be opened, i. 87; small abscesses just beneath the skin, and those in glandular structures should alone be allowed to burst, i. 87; circumstances under which the early opening of abscesses is required, i. 87; circumstances under which abscesses are opened late, i. 87; South recommends the early opening of abscesses just beneath the skin, and in glandular structures, i. 87; opening of abscesses (oncotomia) effected by the knife, escharotics, and the seton, i. 88; deep abscesses with thick coverings should be opened with the bistoury, i. 88; South's condemnation of pressure and squeezing an abscess, i. 88; mode in which escharotics are employed, i. 89; passing a seton through an abscess, i. 89; opening an abscess with a cutting instrument generally preferable, i. 89; South on opening an abscess, i. 89; treatment of cold abscess, i. 90; various plans for opening a cold abscess recommended by Abernethy, Beinl, Walther, Schaack, Rust, Nasse, Zang, and Callisen, i. 90; in selecting his plan of operating, the Surgeon must be guided by the difference of constitution, by the more or less weak state of the cellular walls, and by the size of the swelling, i. 90; constitutional treatment also required, i. 90; Kluge's plan of treating lymph abscesses, i. 91; further treatment after opening the abscess, i. 91; if there be deficiency of power in the part, stimulants may be used, but moist warm poultices are more effectual, i. 92; tonics may be given internally, i. 92; if the opening close too soon, the edges may be drawn asunder, or separated with a probe, i. 92; proud flesh repressed with caustic, i. 92; formation of fistulous passages, i. 92; membrane of the fistula, first pointed out by Hunter, since described by Villermé, Laennec and Breschet, i. 92; Hunter's description of it, i. 92: treatment of the fistulous passage, i. 93; plans of treatment recommended by Langenbeck, H. Dewar, Cramer, Walther, and others, i. 93; Langenbeck's recommendation of the ligature, i. 93; attention to the general health requisite during suppuration, i. 93; abscess of the tonsil, i. 140; opening an abscess of the tonsils with a guarded bistoury or the pharyngotome, i. 141; treatment after the pus has been evacuated, i. 141; in rare cases the abscess becomes external under the jaw, i. 141; Allan Burns on the spontaneous bursting of the abscess, i. 141; it is attended with much danger, i. 142; details of a case in which the trachea was deluged with purulent matter, and death by suffocation ensued, i. 142; Burns' advice in such cases to tap the abscess with trocar and canula, i. 142; in most cases of tonsillar abscess the action of emetics will cause the rupture of the abscess; if not, it must be opened, i. 142; Burns' and South's directions for opening a tonsillar abscess, i. 142; cases of fatal hæmorrhage consecutive to opening a tonsillar abscess mentioned by Portal, Allan Burns, Tyrrell, and Brodie, i. 142; Lawrence's case of alarming hæmorrhage from puncturing an immature tonsillar abscess, i. 142; abscess of the parotid gland sometimes of considerable magnitude, i. 148; Evanson and Maunsell on the suppuration of mumps, i. 149; treatment of mumps after an abscess has formed, i. 150; abscess of the breast, 151; opening the abscess only advisable, when it is very deep, has proceeded slowly, the pain is great, and the fever high, i. 151; South's recommendation that abscess of the breast be opened freely and early, i. 151; advantages of the proceeding, i. 152; deep-seated abscesses in the mammary gland, or between it and the pectoral muscles, i. 153; to be opened early, i. 153; fistulous passages to be laid open throughout their whole length, i. 153: Astley Cooper on chronic abscess of the breast, i. 153; South's case of chronic abscess of the breast, operated on by mistake for scirrhus, i. 153; abscesses in the labia or nymphæ, i. 160; Hunter and Ricord on abscesses complicating gonorrhœa in the female, i. 160; suppuration of the testicle to be feared, when the inflammation is severe, and the pain throbbing, i. 179; suppuration of the testicle rare, when the swelling is sympathetic, i. 180; Astley Cooper on suppuration of the testicle, i. 180; bursting of the abscess sometimes followed by a fungous growth, i. 180; treatment of suppuration and abscess of the testicle, i. 181; South on the treatment of fungus of the testicle, consecutive to abscess, i. 181; seat of the inflammation in lumbar abscess, i. 185; symptoms, i. 185; formation of the abscess, i. 185; general symptoms of suppuration not present if the abscess be not large, i. 185; Astley Cooper on the symptoms of psoas abscess, i. 185; Pearson on the symptoms preceding, and accompanying the formation of the abscess, i. 186; causes, i. 186; English Surgeons generally consider disease of the vertebræ to be the cause, i. 186; Pott on the diseased condition of the spine in this complaint, i. 186; Astley Cooper on the origin of psoas or lumbar abscess in inflammation of the spine and intervertebral substance, i. 186; Abernethy, Lawrence, and Dupuytren on lumbar abscess, generally connected with carious vertebræ, i. 186; South on the origin of the disease from external violence, its origin then being in the spine, i. 187; South on the distinctive characters of psoas abscess from femoral hernia, i. 187; John Pearson on the situation of the external abscess, i. 187; Samuel Cooper's notice of Ramsden's case of lumbar abscess, i. 187; South on the insidious progress of the disease, i. 188; abortive treatment of lumbar abscess, i. 188; opening the abscess, i. 188; Dupuytren on the changes that sometimes take place in the abscess, i. 188; Astley Cooper remarks, that the abscess must be allowed to take its course, i. 188; this opinion controverted by South, i. 188; Cline and Abernethy's experiments to cause absorption of the pus, i. 188; South on issues in the treatment of lumbar or psoas abscess, i. 188; difference of opinion as to the propriety of waiting the self-evacuation of the abscess, or of puncturing and emptying it, either entirely or partially, i. 189; Deckers, Benjamin Bell, and Crowther on tapping the abscess with a trocar, i. 189; Latta recommends the use of a seton in addition, i. 189; this latter practice condemned by South, who prefers opening the abscess with a lancet, i. 189; Abernethy's plan of treatment, i. 189; Astley Cooper and Lawrence support Abernethy's views, i. 190; Kirkland advises to let the abscess break of itself, i. 190; John Pearson prefers making a small aperture, and treating the ulcer in a gentle manner, i. 190; Dupuytren leaves the abscess to nature, i. 190; South's plan of treatment, i. 190; treatment to be pursued after the abscess is opened, i. 191; Pearson and Astley Cooper on the treatment of the sinuous cavities resulting from the abscess, by injections, i. 191; Dupuytren recommends cauterization, or weak injections of nitrate of silver, or nitric acid, i. 191; treatment of the abscess, if inflammation supervene after it has been opened, i. 191; Abernethy on the symptoms of the supervening inflammation, i. 191; Pearson mentions that the larger arteries sometimes ulcerate into the abscess, i. 191; M'Dowell mentions a case in which ulceration took place in a portion of the ileum adhering to the cyst of the abscess, i. 191; whitlow and its varieties, i. 192; South's cases of abscesses external to the joint, i. 210; Astley Cooper and Coulson on the bursting of abscesses of the hip-joint, i. 253; Mackenzie and Scott's cases of abscesses of the hip-joint, i. 254; the abscesses to be freely opened, i. 269; Ford, Wend, van der Haar, Rust, Brodie, and Jaeger, on the treatment of these abscesses, i. 269; Sabatier and Ficher advise their being opened with caustic, i. 269; Larrey, with the red-hot trocar, i. 269; Rust, with the actual cautery, i. 269; Rust advises passing a seton through the joint, i. 269; Brodie and Jaeger recommend free incisions in opening these abscesses, i. 269; Brodie and South on the management of abscesses at the hip, i. 269; subsequent treatment, i. 269; connection of Pott's disease with lumbar and psoas abscess, i. 278; Brodie on the disappearance of psoas abscess, and its appearance elsewhere, i. 278; Brodie on abscess connected with vertebral caries in the neck, i. 284; treatment of abscess resulting from a bruise, i. 334; abscess of the brain, i. 399—see Wounds of the Head; abscesses of the liver consequent on injuries of the head, i. 427; Morère and Duparcque on abscess of the womb, i. 484; abscesses about the anus, i. 726; treatment of abscesses in the neighbourhood of the rectum, i. 728; Brodie on the treatment of large abscesses high up by the side of the rectum, i. 729; Key on abscess in the hernial sac after the operation for strangulated hernia, ii. 42–49; abscesses by the side of the rectum, from the irritation of foreign bodies, ii. 393; abscess of the prostate, ii. 419; abscesses about the neck of the bladder, after the operation of lithotomy, ii. 611.

Acarus scabiei, i. 635.

Acephalocysts, ii. 704.

Achillis' Tendon, Division of, i. 491; tearing of the tendon, i. 491; causes and symptoms, i. 491; laceration of the sheath of the tendon, i. 492; John Hunter on rupture of the tendo Achillis, i. 492; mode of union of the ruptured tendon, i. 492; treatment, i. 492; John Hunter on the treatment of the ruptured tendon, i. 492; various bandages for the cure of the rupture, i. 493; the bandages proposed by Gooch, Petit, Schneider, Desault, and Wardenburg, i. 493; Edmonston's plan of treatment, i. 494; the slippers of Petit, Ravaton, Monro, and Graëfe, i. 494; objections to bandaging, i. 494; after-treatment, i. 494.

Acromion, Fracture of, i. 548.

Adams, Dr., on the acarus scabiei, i. 636.

Adams', Mr., case of longitudinal dislocation of the radius, i. 791; case of hydrocephalocele treated by puncture, ii. 102.

Adams, Mr. **William**, post mortem appearances in a case of hip-disease, i. 262.

Addison's, Mr., artificial leg, ii. 846.

Aetius on aneurism, ii. 197.

Akoluthus' case of extirpation of the upper jaw, the first on record, ii. 994.

Alanson's, Mr., mode of amputation by the circular incision, ii. 890; on amputation just above the ancle, ii. 921; mode of amputating at the shoulder-joint with the circular cut, ii. 958.

Alban's, M., apparatus for fracture of the neck of the femur, i. 569.

Alcock, Mr., on the removal of the edges of the cleft in staphyloraphy, i. 604; mode of operating in staphyloraphy, i. 605.

Alcock, Mr. **Rutherford**, on the difference of the shock to the constitution in severe injuries of the extremities, when occurring in civil life and on the field of battle, ii. 967.

Alibert's, M., division of boils into four kinds, i. 132; dispute with Lugol respecting the acarus scabiei, i. 636; on the varieties of cancer, ii. 761.

Alison, Dr., on the symptoms of inflammation, i. 24.

Allan, Mr., on the effects of the scorpion sting, i. 351; on compression in the treatment of aneurism, ii. 213; on the seat of stricture in the rectum, ii. 336; case of retention of the urine in the ureter, ii. 410.

Alliot, M., on urethroplasty, i. 742.

Alouette's, M. L'., mode of amputating at the hip-joint, by the flap cut with a single flap, ii. 936.

Amesbury's, Mr., fracture-apparatus, i. 512; apparatus for fractured clavicle, i. 551; apparatus for fracture of the olecranon, i. 560; fracture-bed, i. 571; on the formation of a false joint, with a fibro-ligamentous capsule, and a lining membrane, i. 588; on the causes of the non-union of fractured bones, i. 588.

Ammon, M. **von**, on the causes of congenital dislocation, i. 769.

Amputation; the circumstances in gun-shot wounds requiring amputation on the spot, i. 343; Hennen on the nature of the injuries in gun-shot wounds requiring amputation, i. 344; amputation under the circumstances mentioned should be performed early, i. 344; Wiseman, Le Dran, and Ranby on immediate amputation, i. 345; Faure on the propriety of delaying the operation, i. 345; Bilguer's objections to amputation altogether, i. 345; Hunter's objections to primary amputation, i. 345; Hennen, Pitcairn, Gunning, and Guthrie on immediate amputation, i. 346; Guthrie's reasons for an early performance of the operation, i. 347; symptoms which may require the performance of amputation at a time more or less posterior to the date of the injury, i. 347; conditions under which amputation may be necessary in fractures, i. 517; Astley Cooper and Abernethy on the question of immediate amputation, i. 518; South on the principal points to be considered in determining on the necessity for immediate amputation, i. 519; amputation must not be performed during the continuance of symptomatic fever, i. 522; Hunter on the removal of the injured limb during the continuance of hectic, i. 522; South on the objects and occasional results of immediate amputation, i. 523; cases in which amputation is indicated in necrosis, i. 698; the question as to the necessity of amputation in dislocations accompanied with tearing of the soft parts covering the joint, and thrusting out of the head of the bone, i. 768; in compound dislocations of the knee, i. 806; of the ancle-joint, i. 809, of the toes, i. 814; amputation requisite when mortification ensues after the ligature of the principal artery, ii. 226; is rarely successful, ii. 226; the question of amputation in aneurism of bones, ii. 279; amputation requisite in exostosis, when its size does not permit its removal, ii. 676; in osteosteatoma, and in osteosarcoma, amputation should, if possible, be performed above the next joint, ii. 678; amputatio requisite in some cases of spina ventosa, ii. 680; amputation of the breast, ii. 798; of the penis, ii. 801; amputations of the limbs, ii. 887; amputations divided into those which are performed in the continuity of limbs and those at joints, ii. 888; points to be considered in performing amputations, ii. 888; precautions against hæmorrhage, ii. 889; inconveniences of the application of the tourniquet, ii. 889; compression of the principal artery by a capable assistant preferable, ii. 889; Brünninghausen's recommendation to swathe the limb in flannel, to diminish the loss of blood, ii. 889; South on the relative value of the tourniquet, and of compression of the principal artery by a capable assistant in amputation, ii. 889; formation of such wound that the bone can be properly covered by soft parts, ii. 890; by the circular incision, ii. 890; the Celsian operation, ii. 890; objections to this operation, ii. 890; Petit, Mynors, Brünninghausen, Louis, Alanson, Gooch, Bell, Desault, Richter, Boyer, Graefe, Dupuytren, Wilhelm, Valentin, and Portal's modes of operating, ii. 890; flap amputations, ii. 891; Pott, Siebold, and Schreiner's operations, ii. 892; Langenbeck and Scoutetten's operations for disarticulations, ii. 892; the oblique cut of Sedillot and Baudens, ii. 892; the sloping cut of Blasius, ii. 892; retraction of the divided muscles and sawing of the bone, ii. 893; scraping off the periosteum superfluous, ii. 893; Walther and Brünninghausen's management of the periosteum, ii. 893; South on the retraction of the divided muscles by the hand, ii. 893; South and Liston on the use of the saw, ii. 893; South on the duties of the assistant, when the bone is being sawn through, ii. 894; ligature of the divided vessels, ii. 894; historical sketch of the treatment of hæmorrhage after amputation, ii. 894; South on venous hæmorrhage, and the ligature of the veins after amputation, ii. 894; subsequent dressing of the wound, ii. 895; leaving the wound open for some hours after the operation, to guard against after-bleeding, ii. 895; Dupuytren's practice, ii. 895; South on the exposure of the stump, ii. 895; mode of dressing to promote quick union, ii. 895; South on the bringing the edges of the wound together in the horizontal direction, ii. 896; South on the application of the plaster straps after amputation, ii. 896; use of cradles after amputation, ii. 897; South on the use of cradles, and of a substitute for them, after amputation, ii. 897; dressing after flap-amputations, ii. 897; South on the use of sutures after flap-amputations, ii. 897; dressing of the stump, when intended to heal by suppuration and granulation, ii 897; South's objections to the practice, ii. 897; accidents which may ensue after amputation, ii. 897; renewal of the dressing under ordinary circumstances, ii. 897; mode of changing the dressings, ii. 898; withdrawal of the ligature, ii. 898; general treatment after amputation, ii. 898; Benedict's stimulant treatment of stumps, ii. 898; South on the treatment of ligatures after amputation, ii. 898; after-bleeding, and its treatment, ii. 898; ligature of the principal arterial trunk for consecutive hæmorrhage, ii. 898; causes and treatment of parenchymatous bleeding, ii. 899; treatment of consecutive hæmorrhage, from ossification or cartilaginous thickening of the arteries, ii. 899; South on the treatment of after-bleeding, ii. 899; South on the impropriety of tying the main arterial trunk for consecutive hæmorrhage after amputation, ii. 899; South on the use of the actual cautery in after-bleeding, ii. 899; violent inflammation of the stump, and its treatment, ii. 899; erythetic condition of the stump, ii. 899; inflammation of the arteries or veins, a not infrequent cause of death after amputation, ii. 900; symptoms and treatment, ii. 900; insufficient degree

of inflammation, or torpid condition of the stump, ii. 900; treatment of sloughing, ii. 900; of too copious suppuration, ii. 900; causes and treatment of protrusion of the bone, ii. 900; South on the causes and treatment of protrusion of the bone, ii. 901; necrosis of the bone, ii. 901; South on the exfoliation of bone after amputation, ii. 901; ulceration of the bone or soft parts, ii. 901; South on the fungous growth from the medullary cavity, ii. 901; the relative value of the several modes of proceeding in amputation of the limbs in their continuity, ii. 901; objections to the flap-operation, ii. 902; cases in which the flap-operation is suitable, ii. 902; Liston's preference of the flap-operation, and objections to the circular operation, ii. 902; South and Fergusson on the relative value of the flap and circular operations, ii. 903; Fergusson on amputation through the calf of the leg and at the shoulder-joint, ii. 903; South's objections to flap-operations on the leg, ii. 903; the propriety of quick union of stumps, or of the cure by suppuration and granulation, ii. 904; Dupuytren's mode of dressing stumps, ii. 904; South on the union of an amputation-wound, ii. 904; *results of amputation*, ii. 905; Phillips, Lawrie, Potter, and South on the results of amputation, ii. 905. *Amputation in the continuity of the several limbs:—amputation through the thigh*, ii. 906; preparatory steps of the operation, ii. 906; compression of the artery, ii. 906; South on the position of the limb, ii. 906; South on the position and duties of the assistants, ii. 906; the circular operation, ii. 907; division and retraction of the skin and cellular tissue, ii. 907; South on the circular cut and vertical division of the skin laterally, ii. 907; section of the muscles, ii. 907; of the periosteum, ii. 907; sawing the bone, ii. 907; cutting through the muscles on the outside of the thigh, ii. 907; South on the mode of using the knife in amputating, ii. 908; South on the retraction of the soft parts with the hand, while sawing through the bone, ii. 908; bandaging and dressing the wound, ii. 908; South on bandaging and dressing the wound, ii. 908; *amputation through the thigh, with two flaps*, ii. 908; mode of operating, ii. 908; Langenbeck's mode of amputating, ii. 908; Liston's mode of amputating the thigh, by the flap-operation, ii. 909; preferred by Syme and Fergusson, ii. 909; Fergusson and South's reasons why the hind flap should be longer than the front, ii. 909; *amputation through the thigh, with a single flap*, ii. 909; Benedict, Textor, and Jaeger's plan of amputating, with a flap from the outer side, ii. 909; Zang and Textor's plan, with a flap from the inner side, ii. 909; Hey's mode, with the flap from behind, ii. 909; B. Bell, Le Gras, and Foulliay's plan, with a flap from before, ii. 909; mode of operating, ii. 909; Dr. Little's case of amputation, with a flap from behind, ii. 909; Fergusson's recommendation to excise a considerable portion of the sciatic nerve, in that operation, ii. 909; Syme's objections to amputation through the shaft of the thigh-bone, and recommendation to amputate through the condyles or trochanters, ii. 910; commented on by South, ii. 910; Liston's account of eighteen amputations through the thigh, ii. 910; report of twenty-eight amputations through the thigh, ii. 911; Syme and South on the formation of conical stumps, ii. 914; Syme on amputation through the epiphyses, ii. 915; *amputation through the leg*, ii. 915; directions for the operation, ii. 916; application of the tourniquet, ii. 916; South on the application of the tourniquet, ii. 916; modes of operating in amputation with the circular cut, ii. 916; amputation through the leg in its lower third, ii. 917; Salemi, Lenoir, and Baudens' modes of operating, ii. 917; disjointing the head of the fibula, ii. 917; Larrey's amputation through the head of the tibia, ii. 917; South on the seat of amputation through the leg, ii. 917; ligature of the vessels, ii. 918; after-dressing, ii. 918; South on the ligature of the retracted anterior tibial artery, in amputation high up through the leg, ii. 918; South on the treatment of hæmorrhage from the nutritious artery of the tibia, ii. 918; South on the bringing the edges of the wound together horizontally, ii. 918; South on the causes of subsequent sloughing of the integuments, ii. 918; amputation through the leg with a single flap, ii. 919; mode of operating, ii. 919; South's objections to flap operations on the leg, ii. 919; amputation through the leg with two flaps, ii. 919; mode of operating, ii. 920; Liston and Fergusson's mode of operating, ii. 920; amputation just above the ancle, ii. 921; Solingen, Dionis, White, Bromfield, Wright, Alanson, and Hey on this operation, ii. 921; Lawrence and South's cases, ii. 922; Liston's statistics of amputation through the leg, ii. 922; Lawrie's objection to amputation below the knee, ii. 922; South's tabular report of amputations through the leg, ii. 922; *amputation through the upper arm*, ii. 924; steps preliminary to the operation, ii. 924; Liston's statistics of the operation, ii. 925; South on the propriety of having a long stump if possible, ii. 925; South's

tabular report of amputations through the upper arm, ii. 925; *amputation through the fore-arm*, ii. 926; directions for the operation, ii. 926; amputation with a single flap, ii. 926; with two flaps, ii. 926; South on flap amputations through the fore-arm, ii. 926; South's tabular report of amputations through the fore-arm, ii. 927; Liston's cases, ii. 927; amputation through the metatarsal and metacarpal bones, ii. 927; application of the tourniquet, ii. 927; amputation through the metatarsal bone of the great toe, ii. 927; mode of operating when the flap is formed from the sole, ii. 927; when the flap is made from the inner side of the metatarsal bone, ii. 928; the bone best sawn through obliquely from within outwards, ii. 929; mode of operating when the flap is made from the dorsal surface of the metatarsal bone, ii. 929; South on the consequences of amputation through the metatarsal bone of the great toe, ii. 929; amputation through the intermediate metatarsal bones, ii. 929; mode of operating, ii. 929; amputation through the metacarpal bones, ii. 930; amputation through the metacarpal bone of the thumb, ii. 930; South and Liston on amputation through the metacarpal bones, ii. 930; amputation through the fingers and toes, ii. 930; amputation through the phalanges of the fingers, ii. 930; mode of operating, ii. 930; cutting off the finger with a chisel, ii. 931; Mayor on the amputation of the phalanges with the tachytome, ii. 931; *exarticulation or amputation through the joints*, ii. 931; cases in which exarticulation is required, ii. 931; Scoutetten's mode of operating, ii. 931; general directions, ii. 932: condition of the parts around the joint, ii. 932; *exarticulation of the thigh at the hip*, ii. 932; danger and statistics of the operation, ii. 932; Jaeger, Krimer, and South on the operation, ii. 933; cases requiring the operation, ii. 933; La Croix d'Orléans, Perrault, and H. Thomson's cases, ii. 933; the modes of operating, ii. 933; by the circular cut, ii. 934: Abernethy, Veitch, Cole, Jaeger, Kerr, and Graëfe's modes of operating, ii. 934; by the flap-cut with a single flap, ii. 935; Puthod, Hunczorsky, Bryce, L'Alouette, Langenbeck, Delpech, Lenoir, Plantade, and Manec's mode of operating, ii. 935; with two flaps, ii. 937; Blandin, Larrey, Mott, Dupuytren, Lisfranc, von Walther, Vohler, Bell, Béclard, Liston, Begin, and Sanson's modes of operating, ii. 937; the oval cut, ii. 940; Sanson, Guthrie, Scoutetten, and Cornuau's modes of operating, ii. 940; the preference given to Larrey's operation, ii. 940; after dressing, ii. 942; *exarticulation of the leg at the knee*, ii. 942; opinions respecting the propriety of the operation, ii. 943; Jaeger's statistics of the operation, ii. 943; modes of operating, ii. 943; amputation with the flap-cut, ii. 943; Blandin, Rossi, Maingault, and Kern's operations, ii. 943; the circular cut, ii. 944; Velpeau, Cornuau, and Baudens' operations, ii. 944; the operation when the knee-cap is diseased, ii. 944; exarticulation of the ancle-joint an inferior operation to amputation through the leg, ii. 944; *exarticulation of the foot at the ancle*, ii. 944; Velpeau, Baudens, Syme, and Handyside's modes of operating, ii. 944; Syme on the advantages of this operation, ii. 946; *exarticulation of the tarsal bones*, ii. 946; the operation restricted to the removal of the astragalus and navicular bones, ii. 946; Hammond's case of exarticulation of the astragalus, ii. 946; Green's case, ii. 946; general directions for the operation, ii. 946; *amputation of the foot between the astragalus and navicular bones, and the heel and cuboid bones*, ii. 947; Chopart's operation, ii. 947; cases requiring the operation, ii. 947; mode of operating, ii. 947; when an under flap only is formed, ii. 947; when an under and upper flap are formed, ii. 948; Maingault's operation, ii. 948; Langenbeck, Klein, and Richeraud's objections to the upper flap, ii. 948; Walther's operation preferred, ii. 948; Scoutetten's oval cut, ii. 949; Blasius' oblique cut, ii. 949; *exarticulation of the metatarsal bones*, ii. 949; advantages and disadvantages of the operation, ii. 949; Hey, Scoutetten, Lisfranc, and Münzenthaler's modes of operating, ii. 949; *exarticulation of single metatarsal bones*, ii. 951; preservation of the great toe important, ii. 952; mode of operating, ii. 952; *exarticulation of the metatarsal bone of the great toe*, ii. 952; mode of operating, ii. 952; Langenbeck and Scoutetten's operations, ii. 952; *exarticulation of the metatarsal bone of the little toe*, ii. 953; *of the middle metatarsal bones*, ii. 953; consentaneous removal of the diseased tarsal bones, ii. 953; Key, Dieffenbach, and Ruyer's cases, ii. 953; *exarticulation of the toes*, ii. 953; mode of operating with an under flap, ii. 953; with a flap on the dorsal surface, ii. 953; with an outer or inner flap, ii. 953; exarticulation of the second from the first phalanx, ii. 954; of all the toes at once, ii. 954; Scoutetten's operation, ii. 954; *exarticulation of the arm at the shoulder*, ii. 954; various modes of operating, ii. 955; compression of the subclavian artery by an assistant safer than with an instrument, ii. 955; Walther's operation by an upper and an under flap. ii. 955; dressing the wound, ii. 956; Le Dran, Garengeot, Dupuytren, Onsenoort, Lisfranc, and Champesme's modes of operating, ii. 956; the operation on the left arm, ii. 956; Astley Cooper's amputation at the shoulder-joint with a single flap, ii. 956; Hesselbach, Desault, Larrey, Langenbeck, and Dupuytren's modes of operating. ii. 957; exarticulation with the circular cut. ii. 958; Morand, Sharp, Nannoni, Bertrandi, Alanson, Graëfe, Cornuau, Sanson, and B. Bell's operations, ii. 958; Scoutetten's operation with the oval cut, ii. 958; Dupuytren, Béclard, Bonfils, and Blasius' operations, ii. 959; circumstances which guide the choice of either of these methods, ii. 959; removal of the injured acromion or glenoid cavity, ii. 960; practised by Brown, ii. 960; recommended by Robinson and Fraser, ii. 960; Lisfranc's modification of the operation when performed prior to the age of fifteen, ii. 960; gun-shot wounds of the head of the humerus, ii. 960; excision of the head of the bone, or removal of the broken pieces requisite, ii. 960; Larrey's operation for the excision of the head of the humerus in such cases, ii. 960; Guthrie on gunshot wounds causing fracture of the humerus beneath and exterior to the capsular ligament, ii. 960; South on the excision of the acromion, glenoid cavity, or coracoid process in amputation at the shoulder-joint, ii. 961; Liston, South, and Astley Cooper's cases, ii. 961; *exarticulation of the fore-arm at the elbow*, ii. 961; mode of operating according to Textor, ii. 961; Brasdor, Jaeger, Hager, Rodger, Dupuytren, Velpeau, Cornuau, Textor, and Baudens' modes of operating, ii. 962; *exarticulation of the hand at the wrist*, ii. 963; modes of operating, ii. 963; Lisfranc's mode, ii. 963; South on the precautions to be taken in the flap-amputation at the wrist, ii. 963; *exarticulation of the metacarpal bones at their junction with the carpus*, ii. 963; mode of operating in exarticulating the metacarpal bone of the thumb, ii. 964; formation of the upper or under flap, ii. 964; exarticulation of the metacarpal bones of the ring and middle fingers, ii. 964; Langenbeck and Scoutetten's modes of operating, ii. 964; Scoutetten's oval cut in exarticulation of the middle metacarpal bone, ii. 964; mode of operating, ii. 964; in the exarticulation of both middle metacarpal bones, ii. 964; von Walther and Astley Cooper's modes of operating, ii. 965: Riadore, Guthrie, von Graëfe, von Walther, Jaeger, Astley Cooper, Larrey, Tyrrell, and Bennaben's cases of excision of part of the hand, ii. 965; mode of operating in exarticulation of the four metacarpal bones, ii. 965; Troccon's mode of operating, ii. 965; when one metacarpal or metatarsal bone is diseased alone, it should be alone removed, ii. 965; excision of the first metacarpal bone, ii. 965; of the other metacarpal bones, ii. 965; of the first metatarsal bone, ii. 966; of the other metatarsal bones, ii. 966; *exarticulation of the fingers, at their junction with the metacarpal bones, and at their own joints*, ii. 966; Dupuytren and Lisfranc on exarticulation of the middle and ring fingers, ii. 966; Barthelemy on the section of the palmar aponeurosis after exarticulation of the fingers from the metacarpal bones, ii. 966; mode of operating in exarticulation of the joints of the fingers from each other, ii. 966; with two flaps, ii. 966; Lisfranc's flap operation, ii. 966; statistics of amputations, ii. 967; IMMEDIATE AMPUTATION, ii. 967; importance of the question, ii. 967; South on the comparative danger of primary and secondary amputation in severe injuries of the thigh, ii. 967; South's conclusion in favour of primary amputation, ii. 967; South on the minor danger in injuries of the leg or upper extremities, and the consequent propriety of immediate amputation. ii. 967; John Hunter's preference of secondary amputation, ii. 967; John Hunter's objections to primary amputation in severe injuries of the extremities, ii. 967; Astley Cooper's opinion in favour of immediate amputation in such cases, the constitution then having but one shock to sustain, ii. 967; Rutherford Alcock on the difference of the shock to the constitution in such cases, when occurring in civil life, and on the field of battle, ii. 967.

AMUSSAT'S M., case of forcibly breaking through the anchylosis, i. 248; on the torsion of arteries, i. 308; on the mode of operating torsion, i. 309; on the division and thrusting back of the arterial coats, ii. 227; operation for imperforate anus, ii. 326; mode of operating for the formation of an artificial anus at the lower end of the colon, ii. 328; on the treatment of complete retention of urine in stricture, ii. 427; on the introduction of the straight catheter, ii. 431; on the treatment to be adopted when air enters a vein during an operation, ii. 856.

ANCHYLOSIS, i. 240; in anchylosis the opposed ends of the bones are united either by a ligamento fibrous structure or by bone, i. 240; South has seen the connecting medium composed partly of ligamento-fibrous and partly of bony matter, i. 240; John Hunter on anchylosis, i.

241; anchylosis effected by the whole substance of the articulation, i. 241; of two kinds, i. 241; Hunter on the inflammatory and scrofulous diseases of joints causing anchylosis, i. 242; Hunter on soft anchylosis from granulations, i. 242; Hunter on bony anchylosis, i. 242; South's views on anchylosis differ somewhat from those of Hunter, i. 242; South on soft anchylosis from granulations, i. 242; Key on the formation of a vascular membrane in joints as a preliminary to anchylosis, i. 242; South's cases of fibrous anchylosis, i. 243; South's case of the complication of bony and fibrous anchylosis, i. 245; Hunter's case of soft anchylosis from the extension of inflammation from the surrounding parts to the joint, i. 246; Mayo's case of injury to the ancle, followed by the absorption of the cartilages, and effusion and organization of lymph between the ends of the bones, i. 246; process of bony anchylosis, i. 246; the most important form of bony anchylosis, i. 246; Cruveilhier's case of bony anchylosis of the right condyle of the lower jaw, i. 247; other kinds of anchylosis, i. 247; treatment of the soft or ligamento-fibrous anchylosis, i. 247; Velpeau on the treatment of complete anchylosis, i. 247; Barton's operation of cutting out a wedge-shaped piece of bone, i. 247; also performed by Gibson, i. 247; operation for the establishment of a false joint, i. 247; Velpeau favourable to this proceeding, i. 248; performed by Barton and Rodgers with success, i. 248; the operation of breaking through the anchylosis, i. 248; condemned by Velpeau, i. 248; Amussat's case, i. 248; Velpeau on the consequences of the adhesion of the knee-pan to the condyles of the femur, i. 248; Louvrier's apparatus for the rupture of the anchylosis, i. 248; Velpeau's objections to the use of that apparatus, i. 249.

Anchylosis, causes and treatment, ii. 310.

Ancle-joint, dislocation of, i. 807; exarticulation of the foot at, ii. 944; excision of, ii. 983.

ANDERSON, Dr., on the use of raw cotton in the treatment of burns, i. 114; employed by him in cases of old and recent burns, vesicated and sphacelated, i. 114; preparation of the cotton, i. 115.

ANDERSON'S, Mr., operation for tying the common iliac, ii. 256; operation for tying the internal iliac, ii. 257; on the ligature of the external iliac, ii. 261.

ANDRAL'S, M., objections to the term inflammation, and substitution of the term hyperæmia, i. 22.

ANDREWS', Mr., case of penetrating wound of the chest with injury to the lung, i. 441.

ANEL'S, M., operation for aneurism, ii. 214.

ANEURISMS:—definition and varieties, ii. 196; Galen, Aetius, and Paul of Ægina on aneurism, ii. 197; John Hunter's definition of aneurism, ii. 197; distinction between true and false aneurism, ii. 197; Breschet on the four principal kinds of true aneurism, ii. 197; symptoms of aneurism, ii. 198; John Hunter on the coagulation of blood in an aneurism, ii. 198; John Hunter and Hodgson on the bursting of aneurisms, ii. 199; bursting of aneurisms into mucous canals, ii. 199; Dr. Wells' case of an aneurism bursting into another artery, ii. 199; distinguishing characters of circumscribed true and false aneurism, ii. 200; Lawrence on the *bruit de soufflet*, ii. 200; South on the distinguishing characters of circumscribed true and false aneurism, ii. 201; diagnosis of aneurisms from other swellings, ii. 201; Dupuytren, Ferrand, Astley Cooper, and South's cases of aneurism mistaken for abscess, ii. 201; Warner's case of abscess mistaken for aneurism, ii. 202; causes of aneurism, ii. 202; Richerand on the occurrence of aneurism in the dissecting-room servants, ii. 202; Guthrie on the predisposing cause of aneurism, ii. 203; Astley Cooper on the age at which aneurism occurs, ii. 203; John Hunter, Astley Cooper, Hodgson, Guthrie, Lisfranc, and South on the relative frequency of aneurism in the sexes, ii. 203; relative frequency of aneurism in the arteries, ii. 203; Hunter, Hodgson, and Lisfranc on the relative frequency of aneurism in the arteries, ii. 203; more than one aneurism may exist at the same time, ii. 204; Cline and Astley Cooper's cases, ii. 204; Astley Cooper, Tyrrell, Pelletan, and Cloquet's cases of the existence of numerous aneurisms in the same person, ii. 204; condition of the arterial coats in an aneurism, ii. 204; John Hunter admits a diseased condition of the artery as the cause of aneurism, ii. 205; Scarpa's views respecting the non-expansion of all the arterial coats in aneurism not always correct, ii. 205; spontaneous cure of aneurism, ii. 206; circumstances which favour spontaneous cure, ii. 206; John Hunter and South on the spontaneous cure of aneurism, ii. 206; mode of cure of aneurism, ii. 206; enlargement of the collateral circulation, ii. 207; remedies for the treatment of aneurism, ii. 207; treatment of internal aneurism on Valsalva's plan, ii. 207; application of astringent remedies to restore the elasticity of the arterial coats, ii. 207; Guérin, Richerand, and Hodgson on the application of pounded ice to aneurism, ii. 207; compression, ii. 208; of the swelling alone objectionable, ii. 208; of the artery above

the swelling, ii. 208; of the whole limb, ii. 208; Guattani's plan of treating aneurism by compression, ii. 209; John Hunter, Sir W. Blizard, Freer, Hodgson, Richerand, Hutton, Bellingham, Liston, Allan, Greatrex, and Crampton on compression in the treatment of aneurism, ii. 210; cases in which compression may be had recourse to, ii. 213; S. Cooper on the effects of compression in aneurism, ii. 213; ligature of the aneurismal artery, ii. 214; Anel's operation, ii. 214; Desault's case, ii. 215; the Hunterian operation, ii. 215; Hunter's claims to originality in reference to this operation, ii. 215; Ford's cases of spontaneous cure, ii. 215; Sir E. Home on the Hunterian operation, ii. 216; indications for the operation, ii. 217; Sir E. Home on the non-necessity for the existence of large collateral branches, to ensure success in this operation, ii. 217; Hunter and South on the size of the aneurism best fitted for operation, ii. 217; the operation for aneurism by opening the sac, ii. 217; the Hunterian operation, ii. 218; Scarpa and Jones on the application of the ligature, ii. 218; Jones, Hodgson, Travers, Scarpa, Lawrence, Astley Cooper, Maunoir, and Abernethy on the effects produced by the ligature on the arterial coats, ii. 219; John Hunter's operation for tying the femoral artery in popliteal aneurism, ii. 219; Birch's case, ii. 220; South on the importance of opening the sheath to the least possible extent, in applying a ligature round an artery, ii. 221; Cline's cases in which the femoral artery was tied with a broad tape, the ligature being removed some hours after, ii. 222; Crampton and Dease's cases in which the temporary ligature was employed, ii. 222; Lisfranc on the ligature of a diseased artery, without opening the sheath, ii. 222; Abernethy and Galen on the application of two ligatures, and the division of the artery between them, ii. 222; treatment after the operation, ii. 223; Wedemeier's case, in which the aneurism burst after the ligature of the femoral artery, and amputation became requisite, ii. 223; Guthrie and South on the return of pulsation in the aneurism for a short time, after the ligature of the artery, ii. 223; Green's case, ii. 224; accidents consecutive to the operation — secondary hæmorrhage and mortification, ii. 224; circumstances under which secondary hæmorrhage is likely to occur, ii. 224; Hunter's cases of secondary hæmorrhage after the operation, ii. 224; Green's case of secondary hæmorrhage after the ligature of the subclavian, ii. 224; South on the treatment of secondary hæmorrhage, ii. 225; Gunning and Briggs' cases of recurrence of the aneurism after the ligature of the artery, ii. 225; occurrence of mortification of the limb, after the ligature of its principal arterial trunk, ii. 225; causes, ii. 226; advantages and disadvantages of the old operation for aneurism, ii. 226; advantages of the Hunterian operation, ii. 226; the Hunterian operation not applicable in certain forms of aneurism, ii. 227; Thierry and Lieber on torsion of the artery, ii. 227; Amussat's division and thrusting back the internal coats of the artery, ii. 227; mode of operating, ii. 227; Tavignot's subcutaneous tying the superficial arteries, ii. 228; changes effected in arteries by the application of a ligature, ii. 228; cutting into and plugging the aneurism, ii. 228; suture of arterial wounds, ii. 228; application of a ligature with a running knot, ii. 228; E. Home and Phillips on acupuncture of the aneurism, ii. 228; Velpeau on acupuncture of the artery, ii. 228; Pravaz on acupuncture of the sac, and the application of galvanism, ii. 228; cauterization with moxas, ii. 228; introduction of mechanical plugs into the arteries, ii. 228; of threads, ii. 228; various modes of compression, ii. 228; Brasdor's operation, ii. 229; Deschamps' case, ii. 229; Astley Cooper's case, ii. 230; Wardrop and Lawrence on Brasdor's operation, ii. 230; *aneurism of the carotid artery and its branches*, ii. 232; situation and diagnosis, ii. 232; Burns and Syme on carotid aneurism, ii. 232; compensation of the cerebral circulation after ligature of the carotid, ii. 232; Macgill and Mussey's cases of ligature of both carotids, ii. 232; Abernethy's case of ligature of the internal carotid on account of a wound, ii. 233; Fleming's case of ligature of the carotid for secondary hæmorrhage, ii. 233; Astley Cooper's case of ligature of the common carotid, ii. 233; Travers, Robertson, and Zeis' cases of ligature of the carotid, ii. 233; Kuhl's case of ligature of both carotids, ii. 233; tying the common carotid may be performed at three different places, ii. 233; mode of operating immediately above the collar-bone, ii. 234; Zang, Dietrich, and Coates on ligature of the common carotid, ii. 234; the operation below the omo-hyoideus, ii. 235; Astley Cooper on the impediment to the operation offered by the internal jugular vein, ii. 235; if the vein be wounded, it must be tied, ii. 235; the operation above the omo-hyoideus, ii. 235; after-treatment, ii. 236; Astley Cooper on the post-mortem appearances in a case in which he had tied the common carotid 13 years before, ii. 236; aneurism of the branches

of the carotid, ii. 237; tying the external carotid, ii. 237; Dietrich on the ligature of the external carotid, ii. 237; Beclard and Dietrich on the ligature of the lingual artery, ii. 238; ligature of the external maxillary or facial artery, ii. 239; Velpeau and Dietrich on the ligature of this artery, ii. 239; aneurism of the temporal artery, ii. 239; ligature of the artery, ii. 239; aneurism of the occipital artery, ii. 239; its ligature, ii. 239; ligature of the posterior aural, ii. 240; Astley Cooper's case of aneurism of the posterior aural, ii. 240; Bégin's case of aneurism of the middle meningeal artery, ii. 240; aneurism of the branches of the internal carotid in the skull, ii. 240; Sir Gilbert Blane's case of aneurisms of the internal carotid by the side of the sella turcica, ii. 240; Hodgson's case of aneurism of the anterior cerebral, ii. 240; Serres' case of aneurism of the basilar, ii. 240; *aneurism of the subclavian and axillary arteries*, ii. 240; characters of axillary aneurism, ii. 240; ligature of the axillary artery, ii. 241; two modes of operating, ii. 241; the operation by cutting through the pectoralis major, ii. 241; the operation by division of the tendinous interspace between the pectoral and deltoid muscles, ii. 241; South's objections to both these operations, ii. 241; ligature of the subclavian above the collar-bone, ii. 242; Dupuytren, Hodgson, Lisfranc, and Graefe on the section of the scalenus anticus in ligature of the subclavian, ii. 242; Astley Cooper, Ramsden, Sir W. Blizard, T. Blizard, Dr. Colles, Dr. Post, and Liston's cases of ligature of the subclavian above the clavicle, ii. 243; Green and South on ligature of the subclavian, ii. 243; ligature of the subclavian on the tracheal side of the scalenus, ii. 243; the operation very hazardous, ii. 243; mode of operating, ii. 244; Dietrich's description of the operation, ii. 244; South on aneurisms of the aorta and origin of the carotid and subclavian, liable to be mistaken for aneurism of the subclavian, ii. 245; Allan Burns and Hodgson's proposal to tie the innominata, ii. 245; Mott and Graefe's operations, ii. 245; Hodgson on ligature of the innominata, ii. 246; Bujalsky, King, Dietrich and Manec on ligature of the innominata, ii. 246; compensation to the circulation, when the subclavian is obliterated, ii. 247; Key on the post-mortem appearances in a case in which he tied the subclavian 12 years previously, ii. 248; South on the results of injury to the axillary nerves, ii. 249; ligature of the internal mammary, ii. 249; Dietrich's description of two modes of tying the vertebral artery, ii. 249; Nuntiante Ippolito on ligature of the vertebral artery, ii. 250; Möbus' case of vertebral aneurism, ii. 250; case of vertebral aneurism, ii. 250; *aneurism of the brachial, ulnar, and radial arteries*, ii. 251; causes of aneurism of the brachial, ii. 251; Astley Cooper, Hodgson, and Liston on spontaneous aneurism of the brachial, ii. 251; the free anastomosis of the arteries of the arm requires the ligature of the artery near the sac, ii. 251; Astley Cooper and Liston on ligature of the arteries of the fore-arm, ii. 251; W. Cooper's case of radial aneurism, ii. 251; aneurism on the back or front of the hand, ii. 251; ligature of the brachial, ii. 251; the operation in the arm-pit, ii. 252; in the middle of the upper-arm, ii. 252; high bifurcation of the brachial, ii. 252; Tiedemann on the high bifurcation of the brachial, ii. 252; ligature of the brachial at the bend of the arm, ii. 252; of the radial in the upper third of the fore-arm, ii. 253; of the ulnar in the upper third of the fore-arm, ii. 253; in the lower part of the fore-arm, ii. 253; in the region of the wrist, ii. 253; ligature of the end of the radial artery, ii. 253; compensation to the circulation after ligature of the brachial, ii. 254; White and South on the compensating collateral branches, ii. 254; *aneurism of the external and internal iliac*, ii. 254; Astley Cooper, James, and Murray's cases of ligature of the aorta, ii. 254; Guthrie on ligature of the aorta, ii. 255; Monteiro's case of ligature of the aorta, ii. 255; ligature of the common iliac for aneurism of the external or internal iliac, ii. 255; the operation for ligature of the common iliac, ii. 255; Mott, Crampton, Anderson and Salamon's operations, ii. 256; ligature of the internal iliac for aneurism of its branches, ii. 256; the operation for ligature of the internal iliac, ii. 256; Stevens, White, Anderson and Bujalsky's operations, ii. 257; Owen on the post-mortem appearances in Stevens' case, ii. 257; ligature of the gluteal, ii. 257; Carmichael's case, ii. 258; ligature of the ischiatic, ii. 258; of the common pudic, ii. 258; case of aneurism of the internal pudic, ii. 258; *aneurism of the femoral and popliteal arteries and their branches*, ii. 258; Abernethy's case of ligature of the external iliac in the groin, ii. 258; Freer and Astley Cooper's cases, ii. 259; Tait and Arendt's cases of ligature of both the external iliacs, ii. 259; cases in which the external iliac should be tied, ii. 259; description of the operation, ii. 259; Abernethy, Charles Bell, Scarpa, Astley Cooper, Lisfranc, Anderson, Rust, Langenbeck, Delpech, Wright, Post, Bujalsky, and Guthrie on the ligature of the exter-

nal iliac, ii. 261; the operation for ligature of the femoral below Poupart's ligament, ii. 261; Textor, and Froriep on ligature of the femoral below Poupart's ligament, ii. 262; compensation to the circulation after ligature of the external iliac, ii. 262; Astley Cooper on the post-mortem appearances after ligature of the external iliac, ii. 262; ligature of the femoral, for aneurism in the lower third of the thigh, or at the knee-joint, ii. 262; John Hunter on ligature of the femoral, ii. 263; ligature of the popliteal dangerous, and not to be practised, except for wounds, ii. 264; the operation in the middle of the ham, ii. 264; in the upper part of the ham, ii. 264; in the lower part, ii. 264; Jobert's case of ligature of the popliteal in the internal epicondyloid pit, ii. 265; aneurism of the tibial artery, ii. 265; Green's case of aneurism of the posterior tibial, ii. 265; Astley Cooper and Cline jun.'s cases of aneurism of the anterior tibial, ii. 265; Astley Cooper on the treatment of aneurism of the anterior tibial low down, by opening the sac, and tying the artery above and below, ii. 265; ligature of the anterior tibial above the middle of the leg, ii. 266; in the neighbourhood of the instep, ii. 266; of the posterior tibial in the middle or upper third of the leg, ii. 266; South on ligature of the posterior tibial when wounded, ii. 266; ligature of the peroneal artery in the middle of the leg, ii. 266; aneurisms in the sole and back of the foot, ii. 267; compensation to the circulation, when the femoral artery has been tied, ii. 267; Astley Cooper on the post-mortem appearances after ligature of the femoral artery, ii. 267; *aneurismal varix and varicose aneurism*, ii. 268; definition of an aneurismal varix, ii. 268; McMurdo's case of aneurismal varix between the internal jugular vein and carotid artery, ii. 268; characters of the disease, ii. 268; Breschet on the condition of the artery and vein in aneurismal varix, ii. 269; Sennertus, Galen, and William Hunter on aneurismal varix, ii. 269; Lawrence and Liston on the peculiar noise heard in an aneurismal varix, ii. 270; Liston's case of aneurismal varix in the femoral vein and artery, ii. 270; W. Hunter on the distinction between aneurismal varix and false aneurism, ii. 271; treatment, ii. 271; Breschet, Stromeyer, and Astley Cooper on the treatment of aneurismal varix, ii. 271; Atkinson's ligature of the brachial artery for aneurismal varix, ii. 271; varicose aneurism, ii. 271; definition, ii. 271; W. Hunter on varicose aneurism, ii. 272; the operation, ii. 272; Green's case of varicose aneurism, ii. 272; Perry's case of aneurism bursting into a vein, ii. 272; South's comments on the case, ii. 272; *unnatural expansion in the branches and ramifications of arteries*, ii. 273; *branching aneurism*, ii. 273; seat and characters, ii. 273; diagnosis from other swellings, ii. 274; causes, ii. 274; prognosis, ii. 274; treatment, ii. 274; Graefe, Travers, Dalrymple, Wardrop, Rogers, and Dupuytren on the treatment of branching aneurism, ii. 275; *aneurism of the arteries of bone, or aneurism by anastomosis of bone*, ii. 275; symptoms, ii. 275; post-mortem appearances, ii. 276; situation, ii. 276; occasional causes, ii. 276; these aneurisms always preceded by inflammation of the bone, ii. 277; Stanley on pulsating tumours of bones, ii. 277; treatment, ii. 279; *unnatural expansion in the capillary-vascular system*, ii. 279; *teleangiectasy*, ii. 280; is congenital, ii. 280; characters, 280; fungous growths after rupture of the swelling, ii. 280; nature of the disease, ii. 280; complications, ii. 281; *teleangiectasis lipomatodes*, ii. 281; causes, ii. 281; always a local disease, ii. 281; prognosis, ii. 281; treatment, ii. 281; by compression, ii. 282; Abernethy on compression, ii. 282; by extirpation with the knife, ii. 282; with the ligature, ii. 282; advantages of the ligature, ii. 282; Lawrence, Brodie, and South on the application of the ligature, ii. 282; destruction of teleangiectasy by caustic, ii. 283; South on caustic in teleangiectasy, ii. 284; various remedies to induce inflammation and suppuration in the diseased growth, ii. 284; Pattison, Smith, and Tyrrell's cases, ii. 285; tying the principal trunk supplying the diseased growth, ii. 285; if the teleangiectasy be seated in the extremities, and incurable, amputation must be performed, ii. 286; Pauli on the tattooing of moles on the skin, ii. 286.

Ansiaux, M., on the application of the actual cautery in irreducible prolapse of the rectum, ii. 136.

Anus, *artificial*, i. 717; spasmodic contraction of, and anal fissures, i. 734; first clearly described by Boyer, Dupuytren, and Brodie, i. 734; Boyer and Dupuytren on the symptoms of anal fissure, i. 734, 735; Brodie on spasmodic contraction of the anus, i. 735; Dupuytren on the three varieties of fissures, i. 735; Brodie on the spasmodic contraction of the sphincter, attended with ulceration, i. 735; Dupuytren, Brodie, and Boyer on the treatment, i. 736; Boyer's operation for anal fissure, i. 736; *anus imperforate*, ii. 325; congenital narrowing of, ii. 329; spasmodic contraction of, ii. 330.

Aorta, cases of ligature of, ii. 254.

Arden, John of, mentions the *chaudepisse*, i. 163; prescription for an injection for gonorrhœa, i. 169.

Arendt, M.'s, case of ligature of both the external iliacs, ii. 259.

Arm, upper, amputation through, ii. 924; exarticulation of, at the shoulder, ii. 954.

Arnaud's, M., apparatus for fracture of the neck of the femur, i. 569; on the *reduction en masse*, ii. 16; on incision of the hernial sac, and introduction of lint-tents for its radical cure, ii. 24; on dilatation of the stricture in strangulated hernia, without cutting, ii. 38.

Arnott's, Dr., oil-silk tube for strictures of the urethra, ii. 364; on cauterizing the walls of the stricture, ii. 367; operation of lithectasy, ii. 643.

Arnott's, Mr., case of hospital gangrene, i. 69; on severe phlebitis, i. 78; on the morbid appearances in phlebitis, i. 80; case of foreign body in the vagina, the bladder injured, and formation of a calculus, ii. 524; case of malignant tumour of the tongue, in which that organ was removed by ligature, ii. 779; case of diseased undescended testicle, ii. 814.

Arteries, Wounds of, and their consequences, i. 297; closure of slight and longitudinal wounds of, i. 298; Saviard, Petit, and Scarpa on the healing of wounds of, i. 298; artery compressors of Langenbeck, Verdier, Mohrenheim, Dahl, Wegehausen, Moore, Graefe, Scultetus, Heister, Dionis, Plattner, Brambilla. Desault, Leber, Ayres, Bell, Chabert, Lampe, Faulquier, Schendler, Hesselbach, and Joachim, i. 299; von Winter's directions for wounded arteries, i. 301; pressure on the meningeal artery inadmissible, and not requisite, i. 301; Abernethy's case of wounded meningeal artery, i. 301; South on wounds of the pudic artery and artery of the bulb, during the lateral operation for the stone, i. 302; South on the treatment of wounded arteries in the thick fleshy parts of the hand or foot, i. 302; ligature of arteries, i. 303; South's experiments on the carotid of a dog, i. 303; Manec, Dupuytren, and Roux on the introduction of a piece of bougie into an ossified artery, after amputation, i. 304; treatment of a retracted artery, i. 305; South on the ligature of large arteries above and below the wound, i. 305; South on the necessity for cutting down upon a wounded vessel on the sound side of a limb, if nearer the artery than is the part wounded, i. 305; Travers' case of wound of the posterior tibial artery, i. 305; Lawrence, Hennen, Delpech, Walther, Haire, Guthrie, and South on the after-management of the ligature, i. 306; Dr. M'Sweeny on the silk-worm-gut ligature, i. 307; Physick on the animal ligature, i. 307; Astley Cooper on the catgut ligature, i. 307; length of time before the separation of a ligature, i. 307; Callaway and Guthrie's cases, i. 307; secondary hæmorrhage on the separation of a ligature, i. 307; Green's case of secondary hæmorrhage after ligature of the subclavian, i. 307; torsion or twisting of arteries, i. 308; Galen, Amussat, Thierry, Liber, Velpeau, Fricke, and Dieffenbach, on torsion, i. 308; changes produced by torsion, i. 308; Palmer on the torsion of arteries, i. 309; Amussat, Thierry, and Fricke on the mode of practising torsion, i. 309; Dieffenbach's torsion-forceps, i. 310; Kluges's torsion apparatus, i. 310; advantages of torsion, i. 310; Dupuytren, Lorch, Textor, Fricke, Elster, and Bramberger on the effects of torsion, i. 311; Dieffenbach, Dupuytren, and Chelius' objections to torsion, i. 311; South on torsion, i. 311; Ferne and Astley Cooper's cases of accidental torsion, i. 311; cases in which torsion is preferable, i. 311; Köhler and Fricke on the torsion of bony vessels, i. 311; Stilling on the interweaving of arteries, i. 311; use of astringent styptics, i. 312; effects of cauterization on wounded vessels, i. 313; occurrence and management of secondary hæmorrhage, i. 313; circumstances favouring the occurrence of secondary hæmorrhage, i. 313; Cline jun.'s cases of after-bleeding, in which the actual cautery was employed, i. 314; Cline jun.'s clinical observations on after-hæmorrhage, and the use of the actual cautery in such cases, i. 316; Cline jun.'s experiments on arteries, i. 318; South on the treatment of bleeding ossified arteries, ii. 318; if a large artery be wounded from a bruise, it may be necessary to expose it and take it up, i. 334; South on extensive ecchymosis, and the means of diagnosis, when an artery of any material size has been wounded, i. 334; South on the danger of gangrene when a large artery has been wounded, from the distension of the soft parts, i. 334.

Arteriotomy, ii. 864.

Arteritis, Dupuytren and Cruveilhier on, as a cause of dry gangrene, i. 59; South's case of, without gangrene, i. 60; inflammation of the coats of arteries, i. 74; Bouillaud on arteritis, i. 74, 75; Hodgson's cases of, i. 74; Portal's case of inflammation of the aorta, consequent on the recession of measles, i. 74; South's case of arteritis, i. 75.

Arthur, Dr., on the use of the seton in gun-shot wounds, to bring away separated pieces of bone, i. 342.

Assalini, M., on the stanching the bleeding from a wounded intercostal artery, i. 448.
Ashwell, Dr., on the extirpation of ovarian cysts, ii. 492; on the pain in cancer uteri, ii. 818; case of cancer uteri, ii. 818; on the period of life at which cancer uteri is generally developed, ii. 819.
Astragalus, dislocation of, i. 809; case of exarticulation of, ii. 946.
Atkinson's, Mr., case of ligature of the brachial artery, for aneurismal varix, ii. 271.
Attenburrow's, Mr., case of trepanning the spine, i. 538; cases of old men operated on for stone, ii. 569.
Atti, M., on the use of a canula, for maintaining the patency of the artificial duct, in the operation for salivary fistula, i. 714.
Aube, M., on the contagion of itch, dependent on the itch-mite, i. 636.
Aumont's, M., operation for extirpating the testicle, ii. 812.
Austin, Mr., on the formation of urinary calculi, ii. 513.
Autenrieth's, M., opinion, that crusta serpiginosa is connected with itch, i. 634.
Avenzoar, on the acarus scabiei, i. 636.
Avicenna, on congenital dislocation of the hip, i. 769; on the application of caustic, for the radical cure of hernia, ii. 24.
Axillary aneurism, ii. 240.
——— artery, ligature of, ii. 241.
Ayres', Mr., artery-compressor, i. 299.

Babington's, Dr., case of fatal bayonet-wound of the heart, i. 455.
Babington's, Mr., case, illustrative of the peculiar delirium of hydrophobia, i. 369; on the premonitory pains of hydrophobia, i. 371.
Bach, M., on extirpation of bronchocele by ligature, ii. 664.
Bacot's, Mr., objection to the exhibition of corrosive sublimate in cases of syphilis in infants, i. 674; on erethismus mercurialis, i. 677; on the cachexia syphiloidea, i. 678; on the eczema mercuriale, i. 679; on the treatment of mercurial sore-throat, i. 681.
Baillie's, Dr., case of obliteration of the vena cava inferior, ii. 288.
Baillie, Mr., on the local treatment of fractured ribs, i. 549.
Baillif's, M., apparatus for fracture of the patella, i. 579; artificial hands, ii. 848.
Baines, Mr., on the treatment of vesico-vaginal fistula, by drawing off the urine, and by compression, i. 752.
Baker, Mr., on the existence of the acarus scabiei, i. 636.
Balanitis, or external gonorrhœa, i. 176; causes and symptoms, i. 176; Hunter and South on balanitis, i. 176; treatment, i. 176; Ricord and South on the treatment of balanitis, i. 176.
Balfour's, Dr., case of reunion of divided parts, ii. 835.
Balling, M., on cutting away the tunica vaginalis, ii. 506.
Banks', Sir **Joseph**, account of his sufferings, and of Dr. Solander's, from exposure to cold, i. 126.
Banner's, Mr., case of extirpation of the womb, ii. 826.
Bardsley's, Dr., case of hydrophobia, occurring twelve years after the bite had been inflicted, i. 367; his opinion that the disease was not hydrophobia, i. 367; supports his views by the opinions of Darwin, Haygarth, and R. Pearson, i. 367; case illustrative of the peculiar delirium of hydrophobia, i. 369; on the stages of hydrophobia, i. 370; on the diagnosis of tetanus from hydrophobia, i. 380.
Barlow, Mr., on the treatment of torn muscles, i. 495.
Barnes', Dr., case of knife-swallowing, ii. 388.
Barnes', Mr., obturator for vesico-vaginal fistula, i. 751.
Baron's, Dr., case of hydrocephalocele, ii. 198.
Barry, Sir **David**, on the application of the cupping-glass over snake-bites, i. 355.
Barry's, Mr., case of accidental reduction of the dislocation in hip-disease, i. 270.
Barthelemy, M., on the means of preventing the retraction of the urethra in amputation of the penis, ii. 802; case of reunion of divided parts, ii. 835; on the section of the palmar aponeurosis, after exarticulation of the fingers from the metacarpal bones, ii. 966.
Barton's, Dr., operation, of cutting out a wedge-shaped piece of bone for the relief of anchylosis, i. 247; operation for the establishment of a false-joint, in treating anchylosis, i. 248; on the symptoms produced by the bite of the rattlesnake, i. 356; on the treatment of rattlesnake-bites, i. 358; on the employment of the ligature in snake-bites, i. 359; case of cure of ununited fracture, i. 591; operation on the anchylosed femur, ii. 311; operation to remedy the opening of the rectum into the vagina, ii. 327.
Basedow, M., considers dissection wounds agree with malignant pustule, i. 349.
Bateman's, Dr., distinction between erythema and erysipelas, i. 100; acute erysipelas, the vesicular erysipelas of Chelius, i. 100; erratic erysipelas, the erythema symptomaticum of Chelius, i. 102; œdematous erysipelas, the erysipelas from scalp-wounds, i. 102; on

purpura hæmorrhagica, or land-scurvy, i. 621; on the existence of the acarus scabiei, i. 636; case of erythismus mercurialis, i. 677; on eczema rubrum, i. 678.

Baudelocque, M., on the mode of performing the Cæsarian operation, ii. 443.

Baudens', M., oblique cut in amputations, ii. 892; mode of amputating the leg in its lower third, ii. 917; mode of amputating at the knee with the circular cut, ii. 944; at the ancle-joint, ii. 944; mode of operating in exarticulation of the fore-arm at the elbow, ii. 962.

Bauer, M., on the presence of globules in the serum, i. 43.

Bayle, M., on mortification from spurred rye, i. 61; on the pain in cancer uteri, ii. 818.

Baynham's, Mr., case of puncturing the womb in retroversion, ii. 144.

Beaumont, Mr., on increased pressure and supine posture in the radical cure of hernia, ii. 23.

Beck's, Mr., apparatus for fracture of the neck of the femur, i. 570; on accidental cerebral rupture, ii. 100.

Beckett's, Mr., memorandum respecting gonorrhœa, i. 162; prescription for an injection for gonorrhœa, i. 169.

Beclard, M., distinctly of opinion that cartilages are not vascular, i. 227; practice in wounded intestine, i. 464; on the treatment of fistula of the parotid duct, i. 715; on the ligature of the lingual artery, ii. 238; modification of Dupuytren's bilateral section for stone, ii. 597; mode of amputating at the hip-joint with two flaps, ii. 939; mode of amputating at the shoulder-joint, ii. 959.

Bedingfield, Mr., on the treatment of tooth-ache, i. 704.

Beer's, M., cases of malignant pustule, i. 65.

Begin's, M., case of closing and wasting of the portion of intestine below the artificial anus, i. 718; case of aneurism of the middle meningeal artery, ii. 240; operation for the division of the inner fold of the prepuce, ii. 347; directions for œsophagotomy, ii. 386; on the treatment of complete retention of urine in stricture, ii. 427; on the operation for cutting into the urethra in the perinæum, ii. 428; mode of amputating at the hip-joint with two flaps, ii. 940; mode of operating in excision of the knee-joint, ii. 981.

Beinl's, M., opinion, that the so-called lymph-swelling is an extravasation of lymph, i. 48; plan of opening a cold abscess with a lancet, after the previous application of caustic, i. 90.

Bell, Mr. Benjamin, denies the identity of gonorrhœa and syphilis, i. 164; cases of gonorrhœa of the nose, i. 177; on alternate swelling of the testicles, i. 177; on tapping lumbar or psoas abscess with a trocar, i. 189; on the stanching the bleeding from a wounded intercostal artery, i. 447; on the use of the suture in wounded intestine, i. 466; on the expulsion of the suture after union has taken place, i. 468; apparatus for fracture of the patella, i. 579; objections to the use of the catheter in urethral fistula, i. 745; mode of amputating by the circular incision, ii. 891; plan of amputating the thigh with the flap from before, ii. 909; mode of amputating at the shoulder-joint with the circular cut, ii. 958.

Bell's, Sir Charles, opinions relative to the formation of pus, i. 35; on tying the tonsils, i. 145; case of hysterical affection of the hip-joint, i. 249; explanation of the pain in the inside of the knee in hip-disease, i. 252; on the pain in hip-disease, i. 260; on morbus coxæ senilis, i. 260; proposal to saw through the neck of the femur in hip-disease, to promote anchylosis, i. 270; on the operation for trepanning the spine, i. 538, 541; objection to laying open the fracture and using the elevator, or removing its edge by the lenticular, in order to raise the depressed portion of bone in fracture of the sternum, i. 546; on the bent position in fracture of the femur, i. 574; operation for the restoration of the canal of the urethra, i. 744; on the mode of reducing the dislocation of the thumb, i. 795; on the reduction *en masse*, ii. 16; on the ligature of the external iliac, ii. 261; on the ligature of the spermatic veins in varicocele, ii. 297; on the seat of stricture in the rectum, ii. 336; mode of amputating at the hip-joint with two flaps, ii. 939.

Bell, Mr. John, on the arrest of hæmorrhage by nature, i. 297; artery-compressor, i. 299; on the use of the suture in wounded intestine, i. 467.

Bellanger, M., on the reduction of the retroverted womb, ii. 144.

Bellingham, Dr., on compression in the treatment of aneurism, ii. 212.

Bellini's, M., operation for prolapsus uteri, ii. 113.

Belmas', M., operation for the radical cure of hernia, ii. 27.

Belloq, M., on the stanching the bleeding from a wounded intercostal artery, i. 448.

Benaben's, M., case of excision of part of the hand, ii. 965.

Benedict, M., opposed to the radical cure of umbilical rupture by ligature, ii. 83; modification of the German operation of rhinoplasty, ii. 843; stimulant treatment of stumps, ii. 898; mode of amputating the thigh with a flap from the outside, ii. 909.

Bennati, M., on cauterization of the uvula with nitrate of silver in relaxation, i. 147.

Bennett, Dr. J. H., on the oscillation attending the recovery of the circulation in inflammation, i. 29; on the process of resolution, i. 31; on the process of effusion, i. 32; on the process of union by adhesion, i. 290; on the formation of new vessels, i. 291; on the processes of granulation and cicatrization, i. 294.

Bennett's Mr., case of sarcomatous scrotum, ii. 808.

Bent's, Mr., case of excision of a joint, ii. 968; mode of operating in excision of the head of the humerus, ii. 974.

Berard, M., on the removal of the edges of the cleft in staphyloraphy, i. 604; mode of passing the needle, i. 605; fatal case from pneumonia, i. 607; on the ligature of the hernial sac for its radical cure, ii. 24; case of femoral rupture, in which the Fallopian tube was protruded, ii. 71; operation for prolapsus uteri, ii. 112; case of fungus of the dura mater treated by operation, ii. 689.

Berard's, M., jun., case of invagination of the rectum through the anus, ii. 130.

Berdot, M., on dislocation of the head of the thigh-bone downwards and inwards in hip-disease, i. 258; case of reduction of the consecutive dislocation in hip-disease, i. 268.

Berlichingen's, M. Götz von, artificial hands, ii. 848.

Berlinghieri's, M. Vacca, directions for œsophagotomy, ii. 386; operation for stone, ii. 616.

Bernstein's, M., apparatus for fracture of the neck of the femur, i. 569.

Berrens', M., artificial leg, ii. 846.

Bertrandi's, M., mode of reducing dislocation of the humerus, i. 785; mode of amputating at the shoulder-joint with the circular cut, ii. 958.

Berzelius', M., opinion relative to the formation of pus, i. 35.

Beynard, M., on the treatment of spina bifida by closure of the sac, ii. 469.

Bibrach, M., on tying the tonsils, i. 145.

Bichat, M., on the vessels of cartilage, i. 227; on the changes which the substance of bone undergoes in advanced age, i, 497; on the cause of death from the entrance of air into a vein, ii. 856.

Biessey's, M., plan of treatment of ingrowing of the nail by scraping its free surface till nearly its entire thickness is destroyed, then touching it with lunar caustic until it contracts completely, i. 199.

Biett, M., on the solution of chloride of lime in foul, gangrenous, and torpid ulcers, i. 616; on iodine in hard swellings of the testicles, i. 669.

Bigelow's, Dr., employment of ether by inhalation prior to the extraction of a tooth, ii. 1007; to the performance of more important surgical operations, ii. 1008; cases of injurious effects produced by the inhalation of ether, ii. 1008.

Bile, retention of, ii. 408.

Bilguer's, M., objection to amputation, i. 345.

Biliary fistula, i. 716.

Billard's, M., case of cure of cerebral rupture, ii. 99.

Birch's, Mr., case of fatal rupture of the uterus, subsequently to one previously recovered from, i. 484; case of popliteal aneurism, ii. 220.

Bladder, prolapse of, ii. 124; puncturing of, ii. 432; above the pubes, ii. 432; through the rectum, ii. 434; through the perineum, ii. 434; stone in, ii. 544.

Bladder, Wounds of, i. 481; nature and treatment of these wounds, i. 481; removal of foreign bodies in wounds of the bladder, as their presence may cause the formation of a calculus, i. 481; South on rupture or laceration of the bladder in fracture of the pelvis, i. 481; case of grape-shot wound of the pelvis, involving both the rectum and bladder, i. 481; Hennen's case of ball-wound of the pelvis, involving the bladder, i. 481; Cline's sen. case of musket-shot wound of the bladder, the ball remaining, and afterwards extracted by operation, i. 482.

Blagden's, Mr., case of consecutive hæmorrhage after the extraction of a tooth, i. 707.

Blandin's, M., treatment of fracture of the radius or ulna near the wrist, i. 560; on hydrocele caused by gonorrhœa, ii. 499; mode of amputating at the hip-joint with two flaps, ii. 537; at the knee-joint with the flap cut, ii. 943.

Blane, Sir Gilbert, on the period of the accession of tetanus after the receipt of the injury, i. 377; case of aneurism of the internal carotid by the side of the sella turcica, ii. 240.

Blasius, M., on the nature of strangulation, ii. 11; on the causes of club-foot, ii. 176; opposes tenotomy in the treatment of club-foot, ii. 185; operation of chiloplasty, ii. 775; sloping cut in amputations, ii. 892; oblique cut in partial amputation of the foot, ii. 949; mode of amputating at the shoulder-joint, ii. 959.

Blechy, M., on the cause of the difficulty experienced in reducing dislocation of the thumb, i. 795.

Blegny, M., on increased pressure and the supine posture for the radical cure of hernia, ii. 23.

Blizard's, Sir W., case of penetrating wound of the chest, i. 440; on compression in the treatment of aneurism, ii. 210;

case of ligature of the subclavian above the clavicle, ii. 243.

Blizard's, Mr. Thomas, case of hydrocele in front of an inguinal rupture, ii. 61; case of ligature of the subclavian above the clavicle, ii. 243; on the section of the prostate in the operation for stone, ii. 590; case of simple serous cysts of the neck, ii. 695.

Blisters, application of, ii. 871.

Block's, Mr., experiments on the effects of spurred rye on animals, i. 61.

Blood-letting, ii. 860; modes of operating, ii. 860; *opening veins, phlebotomy*, ii. 860; situation where performed, ii. 861; choice of a vein at the bend of the elbow, ii. 861; mode of opening a vein, ii. 861; South's directions for blood-letting from a vein, ii. 862; dressing the wound, and applying the bandage, ii. 862; accidents which occur during the operation, ii. 862; faulty stab, ii. 862; formation of too small an opening, ii. 862; stoppage of the flow of blood, ii. 862; severe pain from wounding a nerve, ii. 862; wounding an artery, ii. 862; wound of a lymphatic vessel, tendon, or aponeurotic expansion, ii. 862; accidents which may occur after the operation, ii. 863; bleeding, ii. 863; inflammation and suppuration, ii. 863; inflammation of the veins or lymphatics, ii. 863; Abernethy on the treatment of traumatic phlebitis, ii. 863; severe pain and even convulsions from partial division of a nervous twig, ii. 863; Abernethy on the complete section of the nervous twig in such cases, ii. 863; use of the snapper dangerous, ii. 863; opening the veins of the fore-arm and hand, ii. 863; blood-letting in the foot, ii. 863; blood-letting in the neck, ii. 863; directions for opening the external jugular vein, ii. 863; *opening arteries*, ii. 864; only performed on the temporal, ii. 864; mode of operating, ii. 864; South and Cline jun. on arteriotomy, ii. 864; *application of leeches*, ii. 864; mode of applying them, ii. 864; description of the blood-leech, ii. 864; of the horse-leech and common leech, ii. 865; means to induce leeches to bite, ii. 865; application of leeches to the mouth, or near the anus, ii. 865; Crampton and Osborne on the application of leeches to the mucous surfaces, ii. 865; treatment after the leeches have dropped off, ii. 865; of the after-bleeding in children, ii. 865; Bricheteau, Lisfranc, Green, and Oliver's cases of fatal hæmorrhage from leech-bites, ii. 866; South on the treatment of the after-bleeding, ii. 866; treatment of ecchymosis, inflammation and suppuration of leech-bites, ii. 867; *scarification*, ii. 867; definition and employment of, ii. 867; *cupping*, ii. 867; mode of operating, ii. 867; dry cupping, ii. 868; South on a substitute for cupping, ii. 868; Dr. Osborne's polytome, ii. 868; South on dangerous hæmorrhage from cupping, ii. 868; relative value of leeches and cupping, ii. 868; Junod's apparatus to cause derivation of blood, ii. 868; South on the relative value of leeches and cupping, ii. 868; South's preference of cupping, ii. 868.

Blundell, Dr., on prolapse of the womb, ii. 103; on relaxation and incomplete prolapse of the womb, ii. 104; on the size of the prolapsed womb and vagina, ii. 105; on the causes of prolapse, ii. 107; case of removal of the inverted womb by ligature, ii. 121; on the symptoms of prolapse of the vagina, ii. 122; on the local symptoms caused by retroversion of the womb, ii. 139; on partial retention of urine in retroversion, ii. 140; on the prognosis in retroversion, ii. 142; on anteversion, ii. 146; case of extirpation of the womb, ii. 825; apparatus for transfusion, ii. 880.

Boerhaave's, M., opinions relative to the formation of pus, i. 35.

Boggie's Staff-surgeon, cases of gun-shot wound, in which a seton was used to bring away separated pieces of bone, i. 342.

Boil or furuncle:—character and symptoms of the disease, i. 132; Walther on the seat of the disease originally in the sebaceous glands of the skin, i. 132; other inflammatory affections of the sebaceous glands, i. 132; Gendrin on the nature of the cores of boils, i. 132; Alibert's division of boils into four kinds, i. 132; the wasp-nest or malignant boil, i. 132; the pustular boil, i. 133; Dr. Copland's asthenic boil—furoncle atonique of Guersaut, i. 133; description of the disease, its symptoms and progress, i. 133; boils often occur in healthy persons without any apparent cause, i. 134; are occasionally critical, i. 134; occur after suppressed perspiration, from neglect of cleanliness, in persons of irregular habits during menstruation, and in the spring, i. 134; they appear sometimes to be dependent on the state of the atmosphere, and are also met with in the chronic form in dyscratic individuals, i. 134; treatment, i. 134; South's plan of treatment by free incision, i. 134; general treatment rarely necessary, i. 134; Ritter's idea that boils depend on the retention of the animal refuse, i. 135; South recommends the employment of general treatment, i. 135.

Boivin, Mad., on anteversion of the womb, ii. 146; case of spontaneous reduction of anteversion, ii. 147.

Bonafont, M., on the treatment of salivary fistula, i. 714.

Bone, aneurism of the arteries of, ii. 275.

Bonfils', M., operation when the cleft in the soft palate is very large and complicated, i. 606; mode of treating ovarian dropsy, ii. 488; case of spontaneous rupture of the ovarian cyst, ii. 491; mode of amputating at the shoulder-joint, ii. 959.

Bonnet, M., on the chemical and microscopic characters of pus, i. 35; on the effects of the resorption of pus, i. 36; operation for the radical cure of hernia, ii. 26; on the application of caustic in varix, ii. 292; on injections of iodine in hydrarthrus, ii. 463; operation for the subcutaneous division of the nerve in mental neuralgia, ii. 885; on the nature of the uniting medium between the two ends of a divided nerve, ii. 886.

Bosch's, M., explanation of wounds from the wind of a ball, i. 339; apparatus for re-breaking a badly-united bone, i. 525.

Bossau, M., mortification from spurred rye noticed by, i. 61.

Böttcher's, M., apparatus for fracture of the olecranon, i. 560; apparatus for fracture of the neck of the femur, i. 569.

Bouillaud, M., on arteritis, i. 74, 75; on the redness of the internal membrane of arteries, i. 75; on severe phlebitis, i. 78.

Boullay, M., on the solution of the chloride of lime in the treatment of foul, gangrenous, or torpid ulcers, i. 616.

Bourgeois', M., observations on malignant pustules, i. 67.

Bouvier, M., on the section of the tendo Achillis in club foot, ii. 182.

Bowman, Mr., considers there is a difference between temporary and articular cartilage, i. 224.

Boyer, M., on the lengthening of the limb in hip disease, i. 257; on dislocation into the foramen ovale in hip disease, i. 259; objects to the subdivision of fractures into complete and incomplete, i. 497; infers the impossibility of simple dislocation of the spine, i. 535: case mentioned by him, i. 535; apparatus for fractured clavicle, i. 551; opposed to Astley Cooper's views on the union of fractures of the neck of the femur, i. 566; apparatus for fracture of the neck of the femur, i. 570; on permanent extension in fracture of the femur, i. 574; apparatus for fracture of the patella, i. 579; on rubbing the ends of the broken bones together in cases of false joint, i. 589; on the treatment of ulcers by sticking plaster, i. 619; on dressing the wound after the operation for rectal fistula, i. 731; on the symptoms of anal fissure, i. 734; on their treatment, i. 736; operation for the cure of anal fissure, i. 736; on dislocation of the upper end of the radius forwards, i. 791; on reduction of dislocation of the astragalus, i. 811; on the nature of strangulation in rupture, ii. 11; on increased pressure and the supine posture for the radical cure of hernia, ii. 23; on cutting away the tunica vaginalis, ii. 506; mode of using Frère Côme's lithotome, ii. 596; on wens, ii. 712; on the cancerous degeneration of steatoma, ii. 715; mode of amputating by the circular incision, ii. 891.

Brachial aneurism, ii. 251.

—— artery, ligature of, ii. 251.

Bradley, Dr., on the blood-fungus, ii. 722.

Braid's, Mr., case of re-union of divided parts, ii. 835.

Brain, and its membranes, injuries of, i. 396; inflammation of, i. 400; compression of, i. 404; concussion of, i. 408.

Bramberger, M., on the effects of torsion, i. 311.

Brambilla's, M., artery-compressor, i. 299.

Branching aneurism, ii. 273.

Brande's, Mr., analysis of the earthy concretions in arteries, i. 77.

Brasdor's, M., bandages for fractured clavicle, i. 551; objected to, i. 551; operation for aneurism, ii. 229: mode of operating in exarticulation of the fore-arm at the elbow, ii. 962.

Braun's, M., apparatus for fractures of the leg, i. 583.

Breast, Inflammation of; situation and character of, i. 150; causes, i. 150; South on the arrest of the secretion of milk, and its absorption, i. 151; treatment of inflammation of the breast, i. 151; abscess of the breast, i. 151; treatment of fistulous openings, i. 151; opening the abscess only advisable when it is very deep, has proceeded slowly, the pain is great, and fever high, i. 151; Langenbeck's treatment of lengthy fistulæ, i. 151; the introduction of tents injurious, i. 151; South's recommendation that abscess of the breast be opened freely and early, i. 151; advantages of the proceeding, i. 152; condemnation of Langenbeck's plan of treating the fistulæ, i. 152; South's treatment of fistulæ, i. 152; milk-knots, i. 152; terminations and treatment, i. 152; inflammation of the breast, unconnected with suckling, i. 152; causes, i. 152; treatment, i. 152; deep-seated abscesses in the gland, or between it and the pectoral muscles, i. 153; to be opened early, i. 153; fistulous passages to be laid open throughout their whole length, i. 153; Astley Cooper on chronic abscess of the breast, i. 153; South's case of chronic abscess operated on by mistake for scirrhus, i. 153; imperfection of the nipples, i. 154; inflammation of the nipple, i. 154; treatment, i. 154; Cooper and Hanney on the treatment of fissured nipples, i. 154.

Breast, cancer of, ii. 783; chronic inflammation of the lymphatics, or of the breast-gland, ii. 788; scrofulous tumors, ii. 790; herpetic and psoric affections, ii. 790; encysted tumors, ii. 790; vesicular scirrhus, ii. 790; hydatid swellings, ii. 791; serocystic tumors, ii. 792; medullary fungus, ii. 793; blood swellings, ii. 793; hypertrophy, ii. 794.

Brefeld's, M., apparatus for fractured clavicle, i. 551; preferred, i. 552.

Brera's, M., plan of treatment preventative of hydrophobia, i. 374.

Breschet, M., on the membrane of the fistulous passage, i. 92; experiment on the communicability of hydrophobia from man to man, and from man to beast, i. 366; on the re-union of fractures, i. 500; on the double formation of bony substance in fracture, i. 501; on the production of callus, i. 501; on the reduction of old dislocations, i. 767; on the causes of congenital dislocations, i. 769; cases of displacement of the heart, ii. 96; on the four principal kinds of true aneurism, ii. 197; on the condition of the artery and vein in aneurismal varix, ii. 269; on the treatment of aneurismal varix, ii. 271; on spermatocele, ii. 295; operation for varicocele, ii. 297; directions for its performance, ii. 299; on the nature of corns, ii. 668.

Bretonneau's, M., treatment of erysipelas by moderate compression, i. 108; condemned by Lawrence and Duncan, i. 108; on pressure in the treatment of burns, i. 117; on tracheotomy in croup, ii. 399.

Bricheteau's, M., case of fatal hæmorrhage from leech-bites, ii. 866.

Briesche's, M., case of softening of the callus, by the internal use of the Carlsbad waters, i. 526.

Briggs', Mr., case of recurrence of the aneurism after the ligature of the artery, ii. 225.

Brodie, Sir B. C., on sudden loss of blood, a cause of mortification, i. 55; case of dry gangrene from inflammation of the principal artery and vein of the limb, i. 59; on the cause of the distinction between dry and moist gangrene, i. 59; gangrene from arterial inflammation a comparatively rare disease, i. 59; this statement denied by Cruveilhier and Dupuytren, i. 59; case of fatal hæmorrhage consecutive to opening a tonsillar abscess, i. 142; on the rarity of affections of the ligaments independent of other structures, i. 206; on the diseases of the synovial membranes, i. 213; on the two varieties of synovial inflammation, i. 213; case of acute synovial inflammation terminating in suppuration and ulceration, i. 214; on the subacute or chronic form of synovial inflammation, i. 215; on gonorrhœal rheumatism and ophthalmia, i. 217; on the pulpy degeneration of the synovial membrane, i. 217; on the causes and progress of the pulpy degeneration, i. 218; on the local treatment of synovial inflammation, i. 219; on the use of friction to promote the absorption of the effused fluid, i. 220; opinion that cartilages are vascular, i. 227; on the ulcerative absorption of cartilage, i. 229; considers that absorption of the cartilages may take place under such circumstances, as to admit of no other agency than that of the vessels of the cartilage, i. 233; considers ulceration of cartilages differs from common synovial inflammation, and from inflammation of the spongy ends of bones, i. 236; on the degeneration of cartilage into a fibrous structure, i. 236; on the period at which ulceration of the articular cartilages may occur, i. 237, on inflammation of the joint-ends of bones, its symptoms, and progress, i. 238; on the consequences of this inflammation, i. 238; on the period at which it is likely to occur, i. 239; observes that it is likely to occur in several joints at once, or in succession, i. 239; opinion that the occurrence of scrofulous disease in the joints has suspended the progress of some other and perhaps more serious disease elsewhere, i. 240; on the diagnosis between scrofulous disease of the joint-ends of bones and ulceration of the articular cartilages, i. 240; on the removal of the articular cartilages in old age, as the result of previous ulceration, i. 241; on the symptoms of hysterical affections of the joints, i. 249; on the local applications in such disorders, i. 250; on ulceration of the cartilage, the primary affection in diseased hip-joint, i. 252, 261; on the difference between hip-disease from ulceration of the cartilages, and that from scrofulous deposit in the cancellous structures of the bones, i. 254; explanation of the lengthening of the limb in hip-disease, i. 257; on dislocation into the foramen ovale in hip-disease, i. 259; on the influence of the primary irritation of the issue, and the maintaining it by repeated applications of caustic potash, or sulphate of copper, i. 265; approved of by South, i. 266; on the use of a seton in the groin, i. 266; on warm bathing, i. 267; on the importance of rest and position, i. 267; on the treatment of abscesses at the hip, i. 269; recommends free incisions in opening these abscesses, i. 269; on the management of abscesses at the hip, i. 269; on the diagnostic symptoms of the diseases of the knee, i. 272; on ulceration of the cartilages of the knee, i. 273; on scrofulous disease in the cancellated structure of the bones of the knee, i. 274; progress of the caries, i. 274; on curvature of the spine from caries, i. 278; on the occurrence of suppuration in caries of the vertebræ, i. 278; on the disappearance of psoas abscess, and its re-appearance elsewhere, i. 278; on the pain in vertebral caries, i. 279; on the extent of the curvature in dorsal caries, i. 279; on the pathology of spinal caries, i. 280; on chronic inflammation of the vertebræ, with ulceration of the inter-vertebral cartilage, i. 280; on the diagnosis between curvature of the spine from caries and that from rickets, i. 281; on the applicability of issues in this disease, i. 283; on the manner in which the disease is cured by anchylosis, i. 283; on vertebral caries in the neck, i. 284; on abscess connected with vertebral caries in the neck, i. 284; on the period of the accession of tetanus after the receipt of the injury, i. 377; on the removal of foreign bodies in injuries of the brain, i. 398; on puncturing the dura mater when the extravasation lies beneath it, i. 406; only employs trepanning in injuries of the head, when secondary symptoms of irritation and pressure require it, i. 412; on softening of the spinal cord after a severe blow, i. 537; on the attempt to set a fracture through the body of a vertebra, i. 538; on the operation for trepanning the spine, i. 541; on fracture of the lower end of the radius, i. 558; on the formation of a false joint, with a fibro-ligamentous capsule and a lining membrane, i. 588; on the operation of sawing off the ends of the broken bone, i. 591; on the impropriety of operating for fistula in phthisical subjects, i. 728; on the treatment of large abscesses high up by the side of the rectum, i. 729; on internal erysipelas following the operation for fistula, i. 732; on spasmodic contraction of the anus, i. 735; on spasmodic contraction of the sphincter, attended with ulceration, i. 735; on the treatment, i. 736; on incomplete internal urinary fistula, i. 740; on the causes of fistula in perineo, i. 744; on the causes of perineal abscess, i. 744; on the treatment of fistula in perineo, i. 745, 746; case of malignant disease consecutive on neglected perineal fistula, i. 746; on the treatment of prolapsus ani in children, ii. 132; on the treatment of prolapsed rectum with piles in the adult, ii. 134; case of wry-neck alternating with insanity, ii. 153; on the application of the ligature in telangiectasy, ii. 282; on the effects of inflammation on the blood in veins, ii. 287; case of varicose veins of the fore-arm, ii. 289; cases of varicose veins of the arm and chest from compression of the subclavian vein, ii. 289; on the application of adhesive plasters in the treatment of varix, ii. 290; on the subcutaneous division of the vein in varix, ii. 292; on the application of caustic in varix, ii. 292; on the removal of internal piles by ligature, ii. 302; cases in which severe symptoms followed the application of the ligature for piles, ii. 303; on the application of the ligature for piles, ii. 303; on excision of piles, ii. 304; on ulceration of the rectum, in connection with spasmodic contraction of the sphincter, ii. 331; on the occurrence of symptoms of strangulated hernia in some cases of stricture, ii. 334; on the post-mortem appearances in stricture of the rectum, ii. 334; on the seat of stricture in the rectum, ii. 336; on the necessity of early treatment in stricture of the rectum, ii. 338; on the distension of the bowel above the stricture by fæces, ii. 338; on the use of bougies, ii. 339; on the internal application of mercurial ointment in stricture of the rectum, ii. 340; on incision of the stricture, ii. 341; on incontinence of urine in stricture of the urethra, ii. 352; on extravasation of urine from ruptured urethra in stricture, ii. 353; on abscesses communicating with the bladder in old cases of stricture, ii. 353; on the complication of stricture with enlarged prostate, ii. 354; case of enlargement of the urethra from stricture, ii. 354; on the formation of cysts of the urethral mucous membrane in stricture, ii. 354; on the occurrence of rigors and fever in stricture ii. 354; on the existence of an indurated mass at the lower portion of the penis in old strictures, ii. 355; on the original seat of stricture, ii. 356; on the use of a full-sized bougie in determining the seat of stricture, ii. 357; on the passing a bougie; ii. 359; on the treatment of stricture with bougies, and on their applicability to the various kinds of stricture, ii. 360; directions for the introduction of bougies, ii. 360; on the destruction of stricture by ulceration, ii. 365; on the use of the armed bougie, ii. 371; case of apple-core in the rectum, ii. 392; case of abscess by the side of the rectum from the irritation of a foreign body, ii. 393; case of foreign body in the bronchus, ii. 401; on abscess of the prostate, ii. 420; on catheterism in inflammation of the prostate, ii. 421; on chronic enlargement of the prostate, ii. 422; on the characters of enlarged prostate, ii. 423; on the rare occurrence of ruptured bladder from retention of urine in enlarged prostate, ii. 424; on the treatment of enlarged prostate, ii. 424; on the treatment of retention of urine from enlarged prostate, and on catheterism in such cases, ii. 425; on effusion of blood into the cellular tissue of the scrotum, ii. 455; on hæmatocele complicated with hydrocele, ii. 456; case of hæmatocele in which the tunica vaginalis ruptured, ii. 456; on hydrarthrus, ii. 462; case of hour-glass hydrocele, ii. 497; case of very large hydrocele, ii. 498; on the spontaneous cure of hydrocele, ii. 499; case of relapse of a hydrocele a long time after the operation, ii. 504; case of foreign body the nucleus of a stone, ii. 524; on the treatment of uric acid gravel, ii. 534; on the connexion between uric acid calculi and gout, ii. 540; on renal calculi of oxalate of lime, ii. 540; on the symptoms of renal calculi, ii. 541; case of renal calculus, ii. 541; on the passage of renal calculi into the bladder, ii. 541; cases of renal calculus communicating with abscess in the loins, ii. 542; on the treatment of renal calculi, ii. 542; on gouty inflammation of the kidneys, ii. 543; on the symptoms of stone in the ureters, ii. 543; case of inspection of calculus in the ureter, ii. 544; on the prevalence of calculi in different classes of society, and at different ages, ii. 545; case of encysted calculus, ii. 547; on the spontaneous breaking up of calculi in the bladder, ii. 548; on sounding, ii. 550; on the existence of calculous symptoms, without the presence of a stone in the bladder, ii. 551; on the use of stone-solvents, ii. 554; on the dilatation of the urethra, ii. 556; on the dilatation of the female urethra, ii. 556; case of encysted calculus removed by the lateral operation, ii. 581; on the external incision in lithotomy, ii. 582; on the section of the prostate and bladder, ii. 588; on contraction of the bladder during lithotomy, ii. 600; on the effects of hæmorrhage in lithotomy, ii. 603; case of fatal venous hæmorrhage in lithotomy, ii. 603; case of secondary hæmorrhage after lithotomy, ii. 604; on the dangerous symptoms which follow the incision of the prostate extending into the loose cellular texture surrounding the neck of the bladder, ii. 609; on the recto-vesical operation, ii. 612; on the expulsion of small calculi from the bladder in women, ii. 617; case of ulceration of the bladder and vagina from the pressure of a large calculus, ii. 617; modification of the vertical cut upwards, ii. 618; on the incontinence of urine consequent on lithotomy in women, ii. 621; on the occurrence of hæmorrhage and of rigors after lithotrity, ii. 623; on the cases in which lithotrity should be performed, and on those in which lithotomy should be preferred, ii. 627; on the nature of corns, ii. 668; on lipoma diffusum, ii. 690; case of fatty tumor connected with the spermatic cord within the abdominal ring, ii. 692; on inflammation of fatty tumors running on to abscess, ii. 693; opinion that fatty tumors sometimes take on a malignant degeneration, ii. 693; case of fatty tumor partially removed by liq. potassæ, ii. 693; on simple cysts in the female breast, ii. 696; case of long-standing scirrhus, ii. 768; on scirrhus of the breast, ii. 784; on scirrhus of the nipple, ii. 786; on the puckering in of the skin in mammary cancer, and on its cause, ii. 787; on sero-cystic tumors of the female breast, ii. 792; on the question as to the propriety of removing a scirrhous breast, ii. 796; on the circumstances permitting the operation, ii. 797.

BROMFIELD, Mr., on incisions and injections of bark and tincture of myrrh in carbuncle, i. 138; invention of the tenaculum, i. 320; case of necrosis from irritation, i. 688; operation for stone in the bladder, ii. 587; on amputation just above the ancle, ii. 921.

BRONCHOCELE, ii. 651; definition and characters, ii. 652; symptoms when the bronchocele is large, ii. 652; varieties, ii. 652; symptoms and treatment of inflammation of the thyroid gland, ii. 653; *vascular or aneurismatic bronchocele*, ii. 653; characters, ii. 653; *lymphatic bronchocele*, ii. 653; characters, ii. 653; seat of the disease, ii. 654; South on lymphatic bronchocele and serous cysts in the neck, ii. 654; *scirrhous bronchocele*, ii. 654; characters, ii. 654; causes of bronchocele, ii. 654; M'Clellan on the cause of bronchocele, ii. 655; Inglis and Copland on the age at which bronchocele is most usual, ii. 655; Dr. Robertson and M'Clellan on bronchocele as a variety of scrofula, ii. 656; prognosis, ii. 656; treatment, ii. 656; in vascular bronchocele, ii. 656; ligature of the superior thyroideal artery, ii. 656; mode of operating, ii. 657; after-treatment, ii. 658; relative value of this operation, and other modes of treatment formerly recommended, ii. 658; the tumour may increase in size after this operation from the enlargement of the inferior thyroid, and its communicating with the superior, ii. 659; Coates and Wickham's case in which the bronchocele ultimately enlarged, after the ligature of the superior thyroid, ii. 659; ligature of the inferior thyroid artery, ii. 659; treatment of lymphatic bronchocele, ii. 659; exhibition of burnt sponge and iodine, ii. 659; dangerous symptoms caused by large doses of iodine, and their treatment, ii. 660; contra-indications to the use of iodine, ii. 660; Graëfe's treatment of bronchocele, ii. 660; Inglis' objections to Coindet's mode of exhibiting iodine, ii. 660; Dr. Gairdner on the dangerous symptoms occasionally caused by iodine, ii. 661; South on the exhibition of iodide of potassium, ii. 661; external remedies for bronchocele, ii. 661; South on the employment of iodide of potassium in the form of ointment, ii. 662; ligature of the superior thyroid artery in lymphatic bronchocele, when it presents a cartilaginous hardness, ii. 662; employment of the seton, ii. 662; mode of applying it, ii. 662; fatal results have occasionally followed its use, ii. 663; incision of the bronchocele, ii. 663; puncturing the bronchocele, ii. 663; Maunoir's treatment by puncture, and irritating injections, and by seton, ii. 663; extirpation very dangerous, and to be almost entirely forbidden, ii. 663; cases in which extirpation is admissible, and mode of operating, ii. 664; Green's case, ii. 664; Mayor and Bach's extirpation of bronchocele by ligature, ii. 664; Regal de Gaillac's extirpation of bronchocele by subcutaneous ligature, ii. 664.

Brown's, Dr., case of a piece of broken delf plate in the œsophagus, ii. 384.

Brown, Mr., treatment of ovarian dropsy, ii. 488.

Brown, Mr., removal of the acromion and glenoid cavity in amputation of the shoulder-joint, ii. 960.

Bruckner, M., on the causes of club foot, ii. 176.

Brugman's, M., opinions relative to the formation of pus, i. 35.

Brünninghausen's, M., straps for fractured clavicle, i. 551; objected to, i. 551; apparatus for fracture of the neck of the femur, i. 569; on permanent extension in fracture of the femur, i. 574; on the spontaneous cure of umbilical rupture, ii. 82; artificial leg, ii. 846; recommendation to swathe a limb in flannel, prior to amputation, to diminish the loss of blood, ii. 889; mode of amputating by the circular incision, ii. 890; management of the periosteum, ii. 893.

Bryce's, Dr., mode of amputating at the hip-joint with the flap cut with a single flap, ii. 936.

Buchanan's, Mr., operation of puncturing the abdomen through the bladder for dropsy, ii. 486.

Bucking's, M., apparatus for fracture of the patella, i. 579.

Bujalsky, M., on ligature of the innominata, ii. 246; operation for tying the internal iliac, ii. 257; on the ligature of the external iliac, ii. 261; case of excision of a portion of the accessory nerves of Willis, ii. 887.

Bulley, Mr., on simultaneous dislocation of the radius forwards and of the ulna backwards, i. 791.

Bullock's, Mr., case of a quartz pebble in the upper part of the larynx, ii. 396.

Burchard's, Mr., obturator for vesico-vaginal fistula, i. 751.

Burder, Mr., on erethismus mercurialis, i. 677.

Burns, Mr. Allan, on the spontaneous bursting of a tonsillar abscess, i. 141; attended with much danger, i. 142; details of a case in which the trachea was deluged with purulent matter, and death by suffocation ensued, i. 142; advice in such cases to tap the abscess with trocar and canula, i. 142; directions for opening a tonsillar abscess, i. 142; case of fatal hæmorrhage consecutive to opening the abscess, i. 142; on the formation of calculi in the tonsils, i. 143; on the frequency of congenital rupture in the female, ii. 65; on carotid aneurism, ii. 232; proposal to tie the innominata, ii. 245; on the difference between fungus hæmatodes and sarcoma medullare, ii. 721; on extirpation of the parotid, ii. 782.

Burns, Mr. John, on the treatment of scrofulous ulcers, i. 624; on prolapse of the vagina, ii. 122; on anteversion of the womb, ii. 146.

Burns:—causes of burns, i. 109; different degrees of burns, i. 109; Dupuytren's subdivision of burns, i. 110; first degree of burn, a bright uncircumscribed redness of the skin, i. 110; second degree, vesication, i. 110; third, more intense burn, with destruction of the cuticle and rete mucosum, i. 110; fourth, gangrenous destruction of the parts, i. 110; symptoms of each degree of burn, i. 110, 111; South on burns, i. 111; burns generally more dangerous than scalds, i. 111; complete immersion of a person in boiling water fatal in ten or fifteen minutes, i. 111; persons whose entire surface has been charred by fire may live for several hours, i. 111; the danger of burns and scalds is the greater in reference to the part injured, i. 111; treatment of the slightest degrees of burns, i. 112; treatment of parts deprived of the cuticle, i. 112; after suppuration is established, i. 112; when mortification is caused by the burn, i. 112; various remedies for burns, i. 112; Fricke's solution of lunar caustic, i. 112; Larrey's plan of treatment, i. 112; Lisfranc's employment of the solution of the chlorate of lime, i. 112; Earle on cold moist applications, i. 113; Hunter on cold, i. 113; Kentish's plan of treatment, i. 113; mode of application of stimulants, i. 113; disapproval of frequent dressings, i. 114; application of raw cotton, i. 114; Gibson, Dallam, and Anderson on raw cotton, i. 114; only applicable in superficial burns, i. 114; employed by Anderson in recent and old burns, vesicated and sphacelated, i. 114; preparation of the cotton, i. 115; application of flour, i. 115; Dr. Ward on the application of flour, i.

115; mode of application, i. 115; Ward's objection to liquid applications, i. 115; modus operandi of the flour, i. 116; Marshall on the application of flour, i. 116; South on the use of flour, i. 116; Hunter on the primary treatment of burns, i. 116; Bretonneau and Velpeau on pressure in the treatment of burns, i. 116; Velpeau considers compression best adapted to cases of burn in the third and fourth degrees, but also applicable in those of the second degree, i. 117; mode of application of compression, i. 117; advantages of this plan of treatment according to Velpeau, i. 117; Earle on the removal of the clothes after burns and scalds, i. 117; South on the treatment of burns and scalds, i. 118; Higginbotham's treatment by the nitrate of silver, i. 119; immediate amputation inadmissible, even when an entire limb has perished; the line of demarcation must be first formed, i. 119; when the destruction of skin on a limb has been very extensive, leaving large wounds without a disposition to heal, and exhausting the strength by the extent of suppuration, amputation should be performed, i. 119; burns from gunpowder, i. 119; the grains of powder to be picked out of the face with a lancet or needle, i. 119; employment of internal remedies, i. 119; the antiphlogistic treatment requisite if the inflammation be high, i. 119; opium required to relieve the pain, i. 119; South on the internal treatment of burns and scalds, i. 120; the occurrence of rigors to be met with stimulants, and external warmth, i. 120; exhibition of opium, i. 120; objections to its use, i. 120: protracted sickness and vomiting an unfavourable sign, i. 120; treatment of febrile excitement, i. 120; support to be given during suppuration, or the separation of sloughs, i. 120; great care required during the process of cicatrization, i. 120; tendency of the cicatrix to contract, i. 120; Earle on the contraction of the cicatrices, i. 120; the contraction the result of a natural process, i. 121; Hunter on the contraction of the granulations during cicatrization, i. 121; South on the effects of this contraction, i. 121; Earle on the effects of the contraction, i. 121; division of the contracted cicatrix followed by the reproduction of the contraction when the wound had healed, i. 121; the same effect followed the removal of the webbed portion of the scar, i. 121; Earle's operation for the removal of the entire cicatrix, i. 121; Earle's case in which this operation was performed, i. 122; case by South, i. 122; Mütter's plastic operations for the relief of deformities from burns, i. 124; occurrence of abdominal disorder and diarrhœa during the cicatrization of extensive burns, i. 125.

Bursæ mucosæ, dropsy of, ii. 458.

BUSH'S, Mr., apparatus for fracture of the lower jaw, i. 529.

BUSHE, Dr., describes two forms of prolapsed rectum, ii. 130; on the characters of prolapse of the rectum, ii. 131; on the diagnosis between prolapsed rectum and hæmorrhoids and intus-susception, ii. 131; on the changes in the mucous membrane of the rectum in old prolapses, ii. 132; on relaxation of the anus, ii. 137; on relaxation of the rectum with invagination of the mucous membrane, ii. 137; on the local symptoms of piles, ii. 301; on the effects of loss of blood from piles, ii. 301; on the removal of internal piles by ligature, ii. 302; on the treatment of hæmorrhage after the removal of piles, ii. 304; on spasmodic contraction of the anus, ii. 331; on stricture of the rectum, ii. 336; on the seat of the stricture, ii. 337.

BUTT'S, Dr., case of excision of the lower part of the ulna on account of necrosis, ii. 977.

Cachexia syphiloidea or mercurialis, i. 678.

Cæsarean operation, ii. 436.

CALCULUS, URINARY: Magendie, von Walther, Austin, Wetzlar, Willis, and Jones, on the formation of calculi, ii. 513; general constituents of calculi, ii. 517; other and more rare constituents, ii. 517; Taylor on the rarity of carbonate of lime calculi, ii. 518; *uric acid and urate of ammonia*, ii. 518; the combination of uric acid with ammonia, and its precipitation in the free state on the cooling of the urine, ii. 518; the development of free acids in the urine, ii. 519; *oxalate of lime*, ii. 519; frequently forms the nucleus of a calculus, but not uncombined, ii. 519; a calculus of almost pure oxalate of lime has been met with, ii. 519; Prout and Walther on the origin of oxalic acid in the urine, ii. 519; presence of free oxalic acid in the urine, ii. 520; combinations of oxalic acid, ii. 520; *cystin*, ii. 521; calculi of cystic oxide rare, ii. 521; usually consist entirely of this substance, but occasionally met with as nuclei of other calculi, ii. 521; formation of cystic oxide calculi, ii. 521; chemical composition, ii. 521; *xanthic oxide, uric oxide*, ii. 521; of very rare occurrence, ii. 521; chemical composition, ii. 521; never occurs in solution, or as a precipitate from the urine, ii. 521; *phosphate of ammonia and magnesia*, ii. 522; causes of its formation, ii. 522; Jones on the phosphatic diathesis, ii. 522; con-

necting material of calculi, ii. 522; causes of the production of gravel and calculi, ii. 522; remote causes, ii. 522; Taylor on the calculi of children, ii. 523; foreign bodies in the bladder act as the nuclei of calculi, ii. 523; foreign bodies rarely coated with uric acid, ii. 524; South on foreign bodies as the nuclei of stones, ii. 524; Astley Cooper, Brodie, and Everard Home's cases, ii. 524; A. White and Arnott's cases of foreign bodies in the vagina, the bladder injured, and formation of calculi, ii. 524; varieties of calculi, ii. 525; characters, ii. 525; characters of uric acid calculi, ii. 525; of urate of ammonia, ii. 525; of mulberry stones, ii. 525; of hempseed calculi, ii. 526; of the earthy phosphates, ii. 526; of the phosphate of lime, ii. 526; of the fusible stone, ii. 526; of the cystic oxide, ii. 526; of xanthic oxide, ii. 526; of carbonate of lime, ii. 526; physical characters of calculi, ii. 526; division of calculi according to their chemical composition, ii. 527; frequency of the different kinds of calculi, ii. 527; *amorphous urinary sediments*, ii. 528; Dr. Prout on lithic or uric acid sediments, ii. 528; characters of yellow sediments, ii. 528; of red or lateritious sediments, ii. 528; of pink sediments, ii. 528; white lithate or urate of soda sediment, ii. 529; characters and accompanying symptoms of the phosphatic sediments, ii. 529; causes of the phosphatic sediments, ii. 530; oxalate of lime sediment, ii. 530; characters of the urine in cystic oxide calculus, ii. 530; *gravel*, ii. 530; definition and characters, ii. 530; Magendie on hairy gravel, ii. 530; symptoms of gravel, ii. 531; Prout on the characters and symptoms of crystallized uric acid gravel, ii. 531; Prout on the crystallized phosphatic sediments, ii. 532; Prout on the rarity of crystallized oxalate of lime gravel, ii. 532; symptoms of the oxalic diathesis, ii. 532; causes and treatment, ii. 533; treatment of gravel, ii. 533; of uric acid gravel, ii. 533; Wetzlar, Jones, Wilson Philip, and Brodie on the treatment of uric acid gravel, ii. 534; Prout on the treatment of a fit of the gravel, ii. 535; Jones on the treatment of uric acid gravel, ii. 535; treatment of cystic oxide gravel, ii. 536; of oxalate of lime gravel, ii. 536; of phosphate of lime gravel, ii. 537; Prout on the treatment of cystic oxide gravel, ii. 537; Prout and Jones on the treatment of the oxalate of lime diathesis, ii. 537; Prout and Jones on the treatment of the phosphatic diathesis, ii. 538; *stones in the kidneys*, ii. 539; situation, ii. 539; Prout on the formation of uric acid calculi in the kidneys, ii. 540; Brodie on the connexion between uric acid calculi and gout, ii. 540; Prout and Brodie on renal calculi of oxalate of lime, ii. 540; Prout on renal calculi of cystic oxide, ii. 541; Prout on the rarity of phosphatic renal calculi, ii. 541; diagnosis, ii. 541; symptoms, ii. 541; Brodie on the symptoms of renal calculi, ii. 541; Astley Cooper and Brodie's cases, ii. 541; progress of stone in the kidney, ii. 541; Brodie on the passage of renal calculi into the bladder, ii. 541; Hevin, Astley Cooper and Brodie's cases of renal calculi communicating with abscess in the loins, ii. 542; Crisp's case of fracture of a renal calculus by sudden exertion, ii. 542; treatment, ii. 542; removal of the calculus by nephrotomy, ii. 542; directions for the operation, ii. 542; Brodie and South on the treatment of renal calculi, ii. 542; Prout on the treatment of nephritis complicating renal calculi, ii. 542; Brodie on gouty inflammation of the kidneys, ii. 543; *stone in the ureters*, ii. 543; symptoms, ii. 543; treatment, ii. 543; Brodie on the symptoms of stone in the ureter, ii. 543; Brodie and Travers' cases of impaction of calculi in the ureters, ii. 544; Cline and Astley Cooper's cases of suppuration of the kidney from impaction of calculi in the ureters, ii. 544; Astley Cooper on the treatment of calculi in the ureters, ii. 544; *stone in the bladder*, ii. 544; origin and varieties, ii. 544; Brodie on the prevalence of calculi in different classes of society, and at different ages, ii. 545; Smith on the statistics of lithotomy, ii. 545; Copland Hutchinson on the rarity of calculus among seamen, ii. 545; forms of calculi in the bladder, ii. 545; characters and situation, ii. 546; sacculated and adherent calculi, ii. 546; Taylor on hourglass calculi, ii. 546; Cline, Mayo, Astley Cooper, Smith and Cheselden's cases of large calculi, ii. 546; Martineau's cases of very small stones, ii. 547; Astley Cooper's case of a great number of calculi in the bladder, ii. 547; Pott's case of fusible calculus in a vesical rupture, ii. 547; Brodie's case of encysted calculus, ii. 547; Wickham's case of calculus enclosed in a bag of lymph incrusted with calculous matter, ii. 548; Brodie, Prout, and Crosse on the spontaneous breaking up of calculi in the bladder, ii. 548; symptoms of vesical calculus, ii. 548; Prout on the symptoms of vesical calculus, ii. 550; sounding the bladder, ii. 550; Klein, Brodie, and South on sounding, ii. 550; Brodie and South on the existence of calculous symptoms, without the presence of a stone in the bladder, ii. 551; South on the simulation of calculus by vesical polypus, ii. 551; measuring the size of

the calculus, ii. 551; South on measuring the calculus, ii. 551; various modes of treatment, ii. 552; internal use of stone-solvents, ii. 552; empirical remedies, ii. 552; efficacy of stone-solvents, ii. 552; Liston's case of partial solution of a stone in the bladder, ii. 553; injection of solvents into the bladder, ii. 553; directions for the use of solvent injections, ii. 553; difference of opinion as to the value of these modes of treatment, ii. 553; Pelouze's experiments, ii. 554; Prout and Brodie on the use of stone-solvents, ii. 554; dissolving stone by means of the galvanic pile, ii. 555; the apparatus and its application, ii. 555; *extraction of the stone through the urethra*, ii. 555; by dilatation, ii. 555; principally applicable to females, ii. 555; mode of effecting the dilatation, ii. 555; Brodie on the dilatation of the urethra, ii. 556; Astley Cooper, Liston and Brodie on the dilatation of the female urethra, ii. 556; *crushing the stone,—lithotrity*, ii. 557; Gruithuisen, Elderton, and Sanctorius' lithotritic instruments, ii. 558; case of the Monk of Citeaux, ii. 558; General Martin's case, ii. 558; improvement of lithotritic instruments, ii. 559; three classes of lithotritic instruments, ii. 559; relative value of these instruments, ii. 560; advantages and disadvantages of the three-limbed perforating forceps, ii. 560; of Jacobson's instrument, ii. 560; of Heurteloup's percuteur, ii. 560; treatment prior to the operation, ii. 561; position of the patient, ii. 561; mode of operating, ii. 561; with the three-limbed perforating forceps of Civiale and Leroy, ii. 562; with Jacobson's instrument, ii. 563; with Heurteloup's percuteur, ii. 563; duration of a lithotriptic sitting, ii. 564; treatment after the operation, ii. 564; escape of sand and calculous fragments, ii. 564; arrest of fragments in the urethra, ii. 565; breaking up the fragments in the bladder, ii. 565; treatment of fragments of calculus fixed in the urethra, ii. 565; by extraction, ii. 566; removal by incision, ii. 566; examination of the bladder when the calculous symptoms have ceased, ii. 566; lithotrity in women, ii. 566; *cutting for the stone,—lithotomy*, ii. 568; definition, ii. 568; should be performed early, ii. 568; circumstances contra-indicating the operation, ii. 568; Cline, Attenburrow and Astley Cooper's cases of old men operated on for stone, ii. 569; Keate, Hunter and Civiale's operations on infants, ii. 569; Green's case of lithotomy in a fat man of 50 years of age, ii. 569; preparation of the patient for the operation, ii. 569; cutting for the stone in man, ii. 570; with the little or Celsian apparatus, ii. 570; mode of operating, ii. 570; objections to the operation, ii. 571; cutting for the stone with the great apparatus, ii. 571; mode of operating, ii. 571; advantages of this operation over the little apparatus, ii. 572; the high operation, ii. 572; mode of operating, ii. 573; modifications of the operation, ii. 574; dressing the wound, ii. 575; the prevention of infiltration of urine from this operation, ii. 575; treatment of the wound for some days, ii. 576; untoward circumstances during and after the operation, ii. 576; advantages and disadvantages of the operation, and cases in which it is applicable, ii. 577; Cheselden on the high operation, ii. 577; the lateral operation, ii. 578; Rau's mode of operating, ii. 579; Cheselden's operation for stone, ii. 580, 585; preparations for the operation, ii. 580; South on the binding a patient prior to the operation, ii. 580; mode of operating, ii. 581; Brodie's case of encysted calculus removed by the lateral operation, ii. 581; South's case of stone undetected by the sound during eight years, ii. 581; Brodie and South on the external incision, ii. 582; Scarpa on the division of the prostate, ii. 583; Key and Liston's modes of operating for stone, ii. 584; Dr. James Douglas and Sharp on Cheselden's operation, ii. 586; Douglas on the dissection of the parts concerned in this operation, ii. 587; Martineau and Bromfield's operations, ii. 587; Brodie on the section of the prostate and bladder, ii. 588; use of Langenbeck's knife, ii. 589; Thomas Blizard, Astley Cooper, and Tyrrell on the section of the prostate, ii. 590; extraction of the calculus, ii. 590; use of the cutting gorget, an improvement on Cheselden's blunt gorget, ii. 591; Cline's gorget, ii. 592; Scarpa's gorget, ii. 592; Astley Cooper on opening the membranous part of the urethra, ii. 592; South on the use of the cutting gorget, ii. 593; objections to the cutting gorgets, ii. 593; South's opinion that these objections are groundless, ii. 593; Le Cat and Pajola's mode of operating for stone, ii. 594; objections to the operation, ii. 595; Frère Côme's operation with the *lithotome caché*, ii. 595; disadvantages of the instrument, ii. 596; Boyer's mode of using Frère Côme's lithotome, ii. 596; Dupuytren's bilateral section, ii. 596; mode of operating, ii. 596; Béclard's modification of the operation, ii. 597; advantages and disadvantages of the operation, ii. 597; extent of the incision in the prostate and neck of the bladder, ii. 598; extraction of the stone, ii. 599; obstacles to the extraction of the stone, ii. 599; *taille en deux tems*, ii. 600; Brodie and South on contraction of the bladder during lithotomy, ii. 600;

extraction of the stone when enclosed by a contracted bladder, ii. 601; of an encysted stone, ii. 601; of a stone lodging in the ureter, and projecting into the bladder, ii. 601; of a stone lying in a hollow, ii. 601; of a stone covered with fungosities, ii. 601; of a brittle and easily breaking stone, ii. 601; dressing the wound, ii. 602; hæmorrhage during the operation, ii. 602; from the branches of the superficial perineal artery, ii. 602; from the inferior hæmorrhoidal, ii. 602; from the internal hæmorrhoidal, ii. 602; from the internal pudic, ii. 602; from the vesical, ii. 602; treatment of the hæmorrhage, ii. 602; Erard, Dupuytren, and von Graefe's compressors, ii. 603; Shaw's case of fatal hæmorrhage in lithotomy, from wound of the dorsal artery of the penis, ii. 603; Brodie on the effects of hæmorrhage in lithotomy, ii. 603; South on the treatment of hæmorrhage during and after the operation, ii. 603; Brodie's case of fatal venous hæmorrhage in lithotomy, ii. 603; symptoms of hæmorrhage into the bladder after the operation, ii. 603; South on secondary hæmorrhage after lithotomy, ii. 604; Brodie, Earle, Travers, Green, and South's cases, ii. 604; wounding the rectum, ii. 605; South on wounding the rectum, ii. 606; convulsions and fainting, ii. 606; after-treatment, ii. 606; South on the treatment to be adopted after the operation for lithotomy, ii. 607; causes and treatment of inflammation after the operation, ii. 609; of spasm, ii. 609; Key on suppurative inflammation of the cellular tissue surrounding the bladder the most frequent cause of death after lithotomy, ii. 609; Brodie on the dangerous symptoms which follow the incision of the prostate extending into the loose cellular texture surrounding the neck of the bladder, ii. 609; treatment of the consecutive hæmorrhage, ii. 610; abscesses about the neck of the bladder, ii. 611; incontinence of urine and impotence, ii. 611; disposition to lithogenesis, ii. 611; opening the bladder from the perinæum, ii. 611: Foubert's operation, ii. 611; cutting for the stone through the rectum, ii. 612; Brodie on the recto-vesical operation, ii. 612; Solly's case of recto-vesical operation, ii. 612; Sanson's two modes of operating, ii. 612; description of the operation, ii. 613; modifications of the operation, ii. 614; after-treatment, ii. 614; advantages and disadvantages of the recto-vesical operation, ii. 615; results of recto-vesical lithotomy, ii. 615; Vacca Berlinghieri and Dupuytren's operations for stone, ii. 616; *cutting for the stone in women*, ii. 616; various modes of operating, ii. 617; Astley Cooper on the symptoms of stone in women, ii. 617; Brodie on the expulsion of small calculi from the bladder in women, ii. 617; Brodie and Astley Cooper's cases of ulceration of the bladder and vagina by the pressure of large calculi, ii. 617; cutting for the stone in women by the lateral operation, ii. 617; mode of operating, ii. 617; the horizontal cut on one or both sides, ii. 618; Liston's operation, ii. 618; the vertical cut upwards, ii. 618; Brodie's modification of the vertical cut upwards, ii. 618; advantages of the vertical cut upwards, ii. 619; the vertical cut downwards, ii. 619; the cut below the pubic symphysis, ii. 619; objections to the operation, ii. 620; Lisfranc's vestibular cut, ii. 620; mode of operating, ii. 620; objections to the operation, ii. 620; von Kern's operation, ii. 620; the vagino-vesical cut, ii. 621; advantages of this operation, ii. 621; Astley Cooper, Brodie, Liston, Hey, and South on the incontinence of urine consequent on the operation, ii. 621; South on dilatation of the female urethra for the extraction of calculi, ii. 622; opening the bladder above the pubic symphysis, ii. 622; *comparison of lithotomy and lithotrity*, ii. 622; equality of the possible evils after the two operations, ii. 623; possible evils from lithotrity, ii. 623; Liston on the breaking or bending of lithotritic instruments in the bladder, ii. 623; Brodie on the occurrence of hæmorrhage and of rigors after lithotrity, ii. 623; comparison of the results in lithotomy and lithotrity, ii. 624; cases in which lithotrity is inapplicable, ii. 624; lithotomy preferable for children, ii. 624; lithotrity preferable in advanced age, females, and in very stout persons, ii. 624; stones of moderate size, and round or oval in shape, best for crushing, ii. 624; cases in which lithotrity is preferable, and cases in which lithotomy should be performed, ii. 625; stricture of the urethra only a temporary contra-indication to lithotrity, ii. 625; palsy of the bladder not a contra-indication, ii. 625; Key on the advantages and applicability of lithotrity, ii. 625; Key on lithotrity with reference to the size of the calculus, ii. 626; Key on the applicability of lithotrity or lithotomy according to the age of the calculous patient, ii. 626; Key on the requisite condition of the bladder for the operation of lithotrity, ii. 627; Key on irritability of the bladder, ii. 627; Brodie, Liston, and South on the cases in which lithotrity should be performed, and on those in which lithotomy should be preferred, ii. 627; *stone in the urethra*, ii. 630; consequences of the impaction of stones or other foreign bodies in any part of the urethra, ii. 630; Travers' case of calculus in the urethra, ii. 630; Home's

case of retention of urine, and consequent mortification from the impaction of calculi in the urethra, ii. 630; Liston's case of a small brass ring encircling the penis, ii. 630; symptoms of stone at the neck of the bladder, ii. 630; treatment and removal by operation ii. 630; South on the treatment of stone in the urethra, ii. 631; symptoms and treatment of stone in the membranous part of the urethra, ii. 631; of stone in the spongy part of the urethra, ii. 631; in the fossa navicularis, ii. 631; the entire urethra, in rare cases, blocked up with calculi, ii. 632; South on the extraction of calculi in the urethra in front of the scrotum without incising the canal, ii. 632; *urinary calculi external to the urinary passage*, ii. 632; are met with in the perinæum or scrotum from the destruction of the walls of the urethra, ii. 632; consequences, ii. 632; may also occur in the vagina or rectum by the destruction of their parietes, ii. 632; Vincent's case of calculi in the perinæum, ii. 632; Vincent's case of calculi between the prepuce and glans penis, ii. 633; treatment of these calculi, ii. 633; *prostatal stones*, ii. 633; varieties, ii. 633; Astley Cooper's case, ii. 634; treatment by operation, ii. 634; Green's case of encysted stone, ii. 634; Travers' case of stone broken up under the use of a constitutional stone-solvent, ii. 634; statistics of the operations of lithotomy at St. Thomas' hospital from 1800 to 1846, ii. 635; *lithectasy, cystectasy*, ii. 642; object of the operation, ii. 642; originally proposed by John Douglas, ii. 642; Dr. Arnott, and Astley Cooper's case, ii. 643; Elliott, Dr. Wright, and Fergusson's cases, ii. 643.

Callaway, Mr., on the hæmorrhage following the extirpation of the tonsils, i. 146; case of retention of a ligature on an artery for four months, i. 307; case of reduction *en masse*, ii. 16; case of removal of degenerated omentum, ii. 40; on the seat of femoral rupture, ii. 70.

Callisen, M., on the removal of the entire skin covering a cold abscess, i. 90; explanation of the lengthening of the limb in hip-disease, i. 257; on the reduction of the consecutive dislocation, i. 268; on the premonitory pains of hydrophobia, i. 371; mode of operating for the formation of an artificial anus at the lower end of the colon, ii. 328.

Callosities, ii. 668.

Camper's, M., explanation of the lengthening of the limb in hip-disease, i. 257; on the causes of club-foot, ii. 176.

Camus', Mr., mode of treating ovarian dropsy, i. 488; case of spontaneous rupture of the ovarian cyst, ii. 491.

Cancer, ii. 754; definition, ii. 755; origin, ii. 755; symptoms of scirrhus, ii. 755; progress of the disease, ii. 755; concealed cancer, ii. 755; ulcerated cancer, ii. 756; condition of the parts in scirrhus, ii. 756; in concealed cancer, ii. 756; microscopic elements of scirrhus, ii. 756; Müller on the four several kinds of carcinoma, ii. 757; Müller on carcinoma simplex and fibrosum, ii. 757; Müller on carcinoma reticulare, ii. 757; Müller on carcinoma alveolare, ii. 757; Müller on carcinoma fasciculatum, ii. 758; Dr. Hodgkin on the development and progress of scirrhus, ii. 758; secondary development of cancerous ulceration, ii. 760; seat of cancer, ii. 760; difference in the progress of cancer in different persons, ii. 761; Alibert on the varieties of cancer, ii. 761; diagnosis of scirrhous tumours, ii. 761; Scarpa on the diagnosis between scrofula and scirrhus, ii. 762; Hodgkin on the diagnosis between scirrhus and medullary fungus, ii. 762; Foy's analysis of scirrhus, ii. 763; *cancer in the skin*, ii. 763; origin and seat, ii. 763; symptoms, ii. 763; occurrence of ulceration, ii. 763; origin of cancer in glands, ii. 764; characters of cancer in mucous membranes, ii. 764; cancer in the bones, ii. 764; characters of cancer in the nerves ii. 764; other tumours in nerves, and their treatment, ii. 764; Cheselden's cases, ii. 765; Astley Cooper's case of tumour in the popliteal nerve, ii. 765; Liston on tumours of nerves, ii. 765; Langstaff, South, Astley Cooper, Cline, and Mayo on tumours in nerves of stumps, ii. 765; cancer a specific disease, ii. 766; cancerous dyscrasy, ii. 767; predisposing and occasional causes of cancer, ii. 767; Hunter on the disposing causes of cancer, ii. 767; prognosis, ii. 767; Scarpa on the nature of scirrhus, ii. 768; Travers on the occasional inertness of scirrhus during life, ii. 768; Brodie and South's cases, ii. 768; treatment of scirrhus and cancer, ii. 768; Leroy d'Etiolles on the statistics of operations for cancer, ii. 768; treatment for effecting dispersion of the tumour, ii. 769; Young, Recamier, and South on compression of scirrhus, ii. 770; removal of the diseased part with the knife or by escharotics, ii. 770; contra-indications, ii. 770; preliminary treatment, ii. 770; necessary to remove all the diseased parts, ii. 770; destruction of a cancerous part by caustic, ii. 771; mode of applying the caustic, and the resulting symptoms, ii. 771; Canquoin's employment of chloride of zinc as a caustic for cancer, ii. 771; Hellmund's mode of applying Cosme's powder, ii. 771; duration of the treatment, ii. 772; symptoms occasionally produced by the arsenical caustic, ii. 772; internal treatment of cancer, ii. 773; exhibition of narcotics to relieve

the pain, ii. 773; *cancer of the lips and cheek*, ii. 773; seat and characters of cancer of the lip, ii. 773; microscopic characters of the disease, ii. 773; malignant but non-cancerous ulceration of the lips, ii. 774; treatment of cancer of the lips by extirpation, ii. 774; contra-indications of the operation, ii. 774; mode of operating when the cancer does not spread down beyond the red part of the lip, ii. 774; South on the operation in such cases, ii. 774; the operation when the cancer has spread beyond the red edge of the lip, ii. 774; union of the divided parts, even when there has been great loss of substance, ii. 775; the operation of chiloplasty, or making a new lip, ii. 775; various modes of operating for chiloplasty, ii. 775; Dieffenbach and Blasius' operations, ii. 775; treatment of cancer of the lip connected with the bone, ii. 776; by operation, ii. 776; of cancer of the cheek, ii. 776; *cancer of the tongue*, ii. 776; characters, ii. 776; prognosis, ii. 777; treatment, ii. 777; by operation, ii. 777; mode of operating, ii. 777; after-treatment, ii. 778; treatment of fungous growths, ii. 778; ligature of the lingual artery, prior to the amputation of the scirrhous portion of the tongue improper, ii. 778; removal of the tongue by ligature, ii. 778; Mirault's operation for ligature of the tongue, ii. 779; Regnoli's operation for the extirpation of the tongue, ii. 779; Arnott's case of malignant tumour of the tongue in which that organ was removed by ligature, ii. 779; *cancer of the parotid gland*, ii. 780; diseases of the parotid, ii. 780; characters of swelling of the parotid, ii. 780; diagnosis between the several tumours of the parotid, ii. 780; treatment in scirrhus and medullary fungus of the parotid, ii. 781; extirpation of the gland a doubtful remedy, ii. 781; arteries in danger of being wounded during the operation, ii. 781; Allan Burns on extirpation of the parotid, ii. 782; mode of operating for the extirpation of the parotid, ii. 782; Goodlad and Langenbeck on the prior ligature of the carotid, ii. 783; after-treatment, ii. 783; *cancer of the breast*, ii. 783; symptoms, characters, and progress, ii. 784; Brodie and South on scirrhus of the breast, ii. 784; characters of scirrhus and cancerous ulceration of the breast, ii. 785; development of cancer of the breast as skin cancer, ii. 785; characters of cancer of the areola, ii. 785; of cancer of the nipple, ii. 785; Astley Cooper on fungous degeneration of the nipple, ii. 786; Astley Cooper on the development of the nipple in the fœtus and its subsequent changes, ii. 786; Brodie on scirrhus of the nipple, ii. 786; symptoms of cancer of the breast, ii. 786; of acute cancer, ii. 786; of chronic cancer, ii. 786; Brodie on the puckering in of the skin in mammary cancer, and on its cause, ii. 787; appearance of scirrhus when cut into, ii. 787; diagnosis between scirrhus and chronic inflammation of the lymphatic vessels, or of the breast gland, ii. 788; symptoms and treatment of the inflammation, ii. 788; symptoms and characters of milk-knots, ii. 789: malignant appearance of milk-knots in old women, ii. 789; Scarpa and South's cases of lacteal swelling, ii. 789; diagnosis between scirrhus and scrofulous tumours of the breast, ii. 790; and herpetic and psoric affections, ii. 790; and encysted tumours, ii. 790; characters of vesicular scirrhus of the breast, or carcinoma mammæ hydatides, ii. 790; this disease a steatomatous degeneration of the gland, ii. 790; Astley Cooper on hydatid swellings of the breast, ii. 791; Astley Cooper on the symptoms and treatment of cellulous hydatids of the breast, ii. 791; Astley Cooper on polypoid hydatids of the breast, ii. 792; Astley Cooper on the lobular hydatids of the breast, ii. 792; Brodie on the serocystic tumours of the female breast, ii. 792; characters of medullary fungus of the breast, ii. 793; of the blood-swelling of the breast, ii. 793; ecchymosis of the breast in girls prior to menstruation, ii. 794; characters of hypertrophy of the female breast, ii. 794; anatomical appearances of the hypertrophied breast, ii. 795; causes, ii. 795; treatment, ii. 795; causes of scirrhus of the breast, ii. 795; prognosis, ii. 796; the question as to propriety of removing a scirrhous breast, ii. 796; opinions of Cline, Home, Astley Cooper, Brodie, and South, ii. 796; Brodie on the circumstances permitting the operation, ii. 797; extirpation of the breast, ii. 797; mode of operating, ii. 797; South on the position of the patient during the operation, ii. 798; South's case of fatal venous hæmorrhage from the extirpation of the breast, ii. 798; South on the after-treatment, ii. 798; amputation of the breast, ii. 798; South's opinion that amputation is not preferable to extirpation, ii. 799; relative value of these operations, ii. 799; requisite to remove all diseased structures, ii. 799; operation for relapse of scirrhus after the removal of the disease, ii. 800; *cancer of the penis*, ii. 800; origin, symptoms, causes, and results, ii. 800; diagnosis, ii. 800; treatment, ii. 800; by operation, ii. 801; amputation of the penis, ii. 801; South on the recurrence of cancer after amputation of the penis, ii. 801; Cline the younger's case, ii. 801;

examination of the organ preliminary to the operation, ii. 801; amputation of the penis by the knife, ii. 801; of the glans alone, ii. 801; in the middle of the organ, ii. 801; Schreger's mode of amputating the penis near the pubic bones, ii. 801; Langenbeck's operation, ii. 802; Barthelemy on the means of preventing the retraction of the urethra, ii. 802; occurrence of after-hæmorrhage, and its treatment, ii. 802; after-treatment, ii. 802; amputation of the penis by ligature, ii. 802; relative value of the two operations, ii. 802; South on the relative value of the two operations, ii. 803; Lisfranc's operation for the removal of cancer of the corpora cavernosa, ii. 803; *cancer of the testicle*, ii. 803; definition of sarcocele, ii. 804; symptoms and progress of scirrhus of the testicle, ii. 804; characters and appearances of sarcomatous degeneration of the testicle, ii. 804; these diseases occasionally complicated with hydrocele, ii. 804; diagnosis of scirrhous and sarcomatous degenerations of the testicle from other swellings of that organ, ii. 805; from thickening of the cellular tissue of the scrotum, ii. 805; characters and causes of that disease, ii. 805; treatment, ii. 805; by operation, ii. 805; Liston, Key, O'Ferrall, and Bennett's cases of sarcomatous scrotum, ii. 806; diagnosis of sarcocele from simple hydrocele, ii. 809; from cystic swelling of the testicle, ii. 809; characters and appearances of cystic swelling, ii. 809; Astley Cooper on the nature of the cysts in cystic swelling, ii. 809; removal of the disease by operation, ii. 809; hydatids of the testicle, ii. 809; diagnosis of sarcocele from thickening of the tunica albuginea, ii. 809; scirrhus of the tunica albuginea, ii. 809; diagnosis of sarcocele from fungus of the testicle or tunica albuginea, ii. 810; from induration of the testicle, ii. 810; from scrofulous swellings, ii. 810; from syphilitic swellings, ii. 810; from medullary fungus, ii. 810; extirpation of the testicle a doubtful remedy in cancerous degeneration, ii. 811; indications and contra-indications of the operation, ii. 811; Walther and Maunoir on ligature of the spermatic artery in sarcocele, ii. 811; mode of operating, ii. 811; mode of operating for extirpation of the testicle, ii. 812; Aumont's operation, ii. 812; South and Astley Cooper on the retraction of the cord during the operation, ii. 812; degeneration of the spermatic cord, and the operation, ii. 812; South and Cline junior on ligature of the spermatic cord, ii. 813; dressing the wound, and subsequent treatment after extirpation, ii. 813; treatment of after-hæmorrhage, ii. 813; treatment of undescended testicle, ii. 813; by operation, ii. 813; extirpation of undescended testicle, ii. 813; South on the treatment of undescended testicle, ii. 814; Paget and Arnott's cases of diseased undescended testicle, ii. 814; *cancer of the scrotum*, ii. 815; characters of chimney-sweep's cancer, ii. 815; Pott and Paris on cancer of the scrotum, ii. 815; Earle's case of chimney-sweep's cancer on the wrist, ii. 816; Astley Cooper and Keate's cases of chimney-sweep's cancer on the cheek, ii. 816; Earle and South on the extension of the disease to the neighbouring parts, ii. 816; Travers on the resemblance of the disease to lupus, ii. 816; cause and treatment, ii. 816; South on the cause of the disease, ii. 816; Pott and Earle on the age at which the disease generally occurs, ii. 816; South's case of recurrence of the disease, ii. 816; *cancer of the womb*, ii. 817; origin of the disease, and primary symptoms, ii. 817; indications on vaginal examination, ii. 817; Montgomery on the origin of the disease in the ova Nabothi, ii. 817; progress of the disease, ii. 817; results of the vaginal examination in the advanced state of the disease, ii. 818; Ashwell, Bayle, and Cayol on the pain in cancer uteri, ii. 818; Montgomery and Ashwell's cases of cancer uteri, ii. 818; diagnosis, ii. 818; Simpson on cauliflower excrescence from the os uteri, ii. 818; period of life at which cancer uteri is generally developed, ii. 819; causes, ii. 819; Ashwell on the period of life at which cancer uteri is developed, ii. 819; treatment, ii. 819; by internal and external treatment, ii. 819; can only be palliative in true scirrhus, ii. 820; examination of the parts in cancer uteri by the speculum, ii. 820; mode of introducing the speculum, ii. 820; Simpson on the mode of using the speculum vaginæ, ii. 820; Osiander on the extirpation of the cancerous neck of the womb, ii. 821; modes of operating, ii. 821; Dupuytren's operation, ii. 821; Canella and Hatin's specula vaginæ, ii. 822; von Walther's case of excision of the cervix uteri, preceded by excising the pubic arch, ii. 822; Recamier's operation when the neck of the womb is softened or destroyed, ii. 822; Lisfranc's operation, ii. 822; Colombat's hysterotome, ii. 822; destruction of the degenerated womb by caustic, ii. 822; Mayor's ligature of the neck of the womb, ii. 822; mode of applying caustic potash to destroy the cancerous cervix uteri, ii. 822; cases in which this proceeding is applicable, ii. 823; extirpation of the whole womb, ii. 823; Struve, Gutberlat, and Wenzel on extirpation of the womb, ii. 823; Langenbeck and Laud-Wolf's cases of extirpation of the cancerous womb, ii.

823; Recamier's cases of removal of the womb by ligature, ii. 824; Sauter's directions for the operation of extirpation, ii. 824; dressing and after-treatment, ii. 825; von Siebold, Langenbeck, Paletta, Holcher, Blundell, and Banner's cases, ii. 825; Delpech, Dubled, and Recamier on the extirpation of the womb, iii. 826; Roux' cases, ii. 828; the difficulty and danger of the operation, ii. 828; Gendrin's directions for the operation, ii. 828; Heath's case of excision of the uterus by the abdominal section, ii. 829.

Cancrum oris. *Vide* Mortification.

CANELLA'S, M., speculum vaginæ, ii. 822.

CANQUOIN, M., on the use of the chloride of zinc as a caustic in cancer, ii. 771.

CANTON, Mr., on the existence of the acarus scabiei, i. 636.

CAPURON, M., on an epidemic vaginal catarrh, i. 161.

CARBUNCLE:—nature of the disease, i. 135; distinguished from boil and malignant pustule, i. 135; symptoms, i. 135; varieties, i. 135; Hunter on the inflammation that produces carbuncle, i. 135; his observation, that there are generally more carbuncles than one, not confirmed by South, i. 136; his opinion that carbuncle has some affinity to boils, i. 136; Copeland on anthrax, i. 136; Perrez on the physiology of carbuncle, i. 136; benignant carbuncle, i. 137; carbuncle, the consequence of metastasis of deleterious matter, i. 137; malignant carbuncle never connected with previous fever, i. 137; English surgeons do not admit the metastatic origin of carbuncle, i. 137; Rayer says it occurs most frequently in spring and summer, i. 137; danger of carbuncle depends on its size, seat, presence of many such swellings, the constitution of the patient, and the connecting general disease, i. 137; Astley Cooper on the danger of carbuncle on the head and neck, i. 137; South on the rareness of carbuncle on the head, i. 137; general and local treatment of benignant carbuncle, i. 137: von Walther on incisions in carbuncle, i. 137; Wiseman on incisions in carbuncle, i. 137; Bromfield on incisions and injections of bark and tincture of myrrh, i. 138; Cooper, Abernethy, Dupuytren, and Rayer, on incisions, i.138; Pearson against incisions, i. 138; South's treatment of carbuncle, i. 138; Physick's treatment of carbuncle, i. 138; Coates on the application of blisters in carbuncle, i. 138; Perrez on the treatment of carbuncle, i. 139; Pouteau on the application of caustic, and the actual cautery, i. 139; treatment of malignant carbuncle, i. 139.

CARIES, i. 681; nature and appearances of the disease, i. 681; Lawrence's definition of caries, i. 682; Miescher on the granulations attending caries, i. 682; Syme on the distinguishing character of caries, i. 682; Mayo on the progress of caries, i. 682; symptoms, i. 682; diagnosis, i. 683; Miescher and Syme on the characters of caries, i. 683, 684; causes, i. 684; Delpech on the diseased condition of the bones in syphilis, not caries, but necrosis, i. 684; Mayo on inflammation as the cause of caries, i. 684; Miescher on the seat of the various kinds of caries, i. 684; prognosis, i. 685; general and local treatment, i. 685; Rust, Fricke, Mayo, Lawrence, and Syme on the treatment of caries, i. 686; removal of the diseased bone, i. 687; *caries of the skull bones*, i. 698; situation, causes, and symptoms, i. 698; South on the consequences of caries, or necrosis in the mastoid process, i. 698; South on necrosis of the vault of the skull, i. 699; South's case of extensive destruction of the vault of the skull, i. 699; South on caries of the bones of the face, i. 699; South on the disease in bones from mercury and syphilis, i. 699; Syme's case of destruction of the bones of the face, i. 699; causes and prognosis of caries of the skull-bones, i. 699; treatment, i. 699; *caries of the teeth*, i. 700; characters and situation of the caries, i. 700; South on inflammation and suppuration in the tooth-socket without caries, i. 701; symptoms of caries at the root of the tooth, i. 701; caries of the alveolar process, i. 701; diseased changes in the maxillary antrum, i. 701; epulis, i. 701; South on the symptoms and treatment of sympathetic disease of the antrum, i. 701; Liston and South on epulis, i. 702; causes of caries, i. 702; Coffinière on toothache as a counter irritant, i. 703; treatment, i. 703; remedies to resist the further destruction of carious teeth, i. 703; filing and stopping the teeth, i. 703; destruction of the nerve of the diseased tooth by the actual cautery, or sulphuric acid, i. 703; South on the stopping a carious tooth, i. 703; preventive treatment of caries, i. 703; treatment of tooth-ache, i. 704; South and Bedingfield on the treatment of tooth-ache, i, 704; extraction of the tooth sometimes necessary, i. 704; excision of the carious crown, i. 704; the different instruments used in the extraction of teeth, i. 704; extraction of the front teeth, i. 705; of the back teeth with the key, i. 705; with the pelican, i. 705; use of the punch, i. 705; extraction of stumps and roots of teeth; i. 706; accidents which may occur in extracting teeth, and their treatment, i. 706; occasional consecutive hæmorrhage, i. 706; inflammation and suppuration of the gum,

i. 706; caries of the alveolar process, i. 707; South on the consecutive hæmorrhage in the hæmorrhagic diathesis, and its treatment by the actual cautery, i. 707; Blagden, South, and Davenport's cases. i. 707, 709; Cortez, Cullen, Kendrick, and Dr. Ryan on the treatment of the consecutive hæmorrhage, i. 709; South on the necessity of adopting preventive measures immediately after the extraction of a tooth, when the hæmorrhagic diathesis is known to exist, i. 709; tooth-fistulas, i. 709; carcinomatous excrescences on the gums, i. 709; treatment, i. 709.

Carlisle's, Sir A., tourniquet, and its mode of application, i. 300.

Carmichael, Mr., on severe phlebitis, i. 78; injection of a strong solution of nitrate of silver in gonorrhœa, i. 170; objections to the terms syphilis, syphyloidal, and pseudo-syphilis, i. 652; bases his arrangement of venereal complaints on the character of the eruption, i. 652; does not admit the existence of mercurial disease, i. 676; on eczema mercuriale, i. 679; case of ligature of the gluteal artery, ii. 258; case of excision of the head of the femur, ii. 978.

Carotid aneurism, ii. 232.

——— artery, common, ligature of, ii. 234; tying the external carotid, ii. 237.

Carpue's, Mr., cases of the Taliacotian operation, ii. 831.

Carpus, fracture of the bones of, ii. 562; exarticulation of the metacarpal bones at, ii. 963.

Carswell, Dr., on the genus carcinoma, ii. 716.

Cartilage, Inflammation of. *See* Inflammation of the Joints.

Cartilages of the larynx, fracture of, i. 530.

——— costal, dislocation of, ii. 777.

Catheter, introduction, ii. 429; straight, introduction of, ii. 430; female, introduction of, ii. 432.

Catheterism, forcible, ii. 427.

Cauterization, ii. 880.

Cautery, actual, ii. 881.

Cayol, M., on the pain in cancer uteri, ii. 818.

Celsus, on the extirpation of the tonsils by cutting and by tearing out, i. 145; on the removal of the relaxed uvula by cutting, i. 147; on the use of the ligature for wounded vessels, i. 320; on the application of a ligature above a viper's bite, i. 354; observations on the innocuous qualities of the poison of serpents when introduced into the mouth confirmed by Russell, i. 354; on rubbing the ends of the broken bone together in cases of false joint, i. 589.

Cerebral Hernia, ii. 97.

Cestoni, M., on the acarus scabici, i. 636.

Chabert's, M., artery-compressor, i. 299.

Champesme's, M., mode of amputating at the shoulder joint, ii. 956.

Chauliac's, Guy de, account of the operations of the Arabian physicians in false joints, i. 592; on ligature of the hernial sac for its radical cure, ii. 24.

Chaussier's, M., cases of actual protrusion of the heart, ii. 96; experiments on the excision of joints, ii. 969.

Chaumet's, M., case of partial resection of the clavicle, ii. 1004.

Cheek-bones, fracture of, i. 527.

Cheek, cancer of, ii. 776.

Cheselden, Mr., on ligature of the tonsils, i. 145; his operation preferred by Else, i. 145; on the immovable apparatus for fractures, i. 504; case of large urinary calculus, ii. 546; on the high operation for stone, ii. 577; operation for stone, ii. 580-5; cases of tumours on nerves, ii. 765.

Chesman's, Mr., case of spina bifida, ii. 465.

Chest, Wounds of the, i. 438; either superficial or penetrating, i. 438; treatment of superficial cuts and sabre wounds, i. 438; consequences and treatment of bruises and shot wounds of the coverings of the chest, i. 439; penetrating wounds of the chest, i. 439; indications of a penetrating wound, i. 439; South on the examination with the probe, &c., in penetrating wounds of the chest, i. 439; South on the condition of the lungs when the chest is opened, i. 439; Williams' experiments and conclusions, i. 439; Astley Cooper on the signs of wounded lungs, i. 440; Hennen on the course taken by balls in wounding the chest, i. 440; Maiden and Sir W. Blizard's case of penetrating wound of the chest, i. 440; Andrews' case of penetrating wound of the chest, with injury to the lung, i. 441; Astley Cooper's case of wound of the intercostal muscles by an iron spindle, ii. 443; Everard Home on the appearances in the lungs thirty-two years after their having been wounded by a ball, i. 443; Hennen and Gregory on the prognosis of wounds of the chest, i. 444; varieties of penetrating wounds of the chest, i. 444; simple penetrating wounds of the chest, and their treatment, i. 444; penetrating wounds of the chest complicated by the presence of foreign bodies, i. 444; Larrey's case of excision of a portion of a rib for the removal of a ball, i. 445; presence of bullets in the chest without causing inconvenience, i. 445; instance of a ball remaining in the lungs for twenty years without causing mischief, i. 445; occurrence of hæmorrhage in penetrating wounds of the chest, i. 445; symptoms of hæmorrhage, i. 445; the most certain and determinate signs of extravasation of blood in the chest, i. 445; the less certain and constant symptoms, i.

446; effects of the extravasation of blood into the cavity of the chest, i. 446; Hennen on the occurrence of primary and secondary hæmorrhage in incised or punctured wounds of the chest, i. 446; very difficult to determine the source of the hæmorrhage in penetrating wounds of the chest, i. 446; injury of the intercostal artery, i. 446; Richter's piece of cardboard, and Reybard's canula useless in such cases, i. 447; Graefe's case of fatal gun-shot wound of the intercostal artery, i. 447; various plans for stanching bleeding from the intercostal artery proposed by Gerard, Goulard, Leber, Reybard, Nevermann, Benj. Bell, Lottery, Quesnay, Bellocq, Harder, Desault, Sabatier, Medin, Assalini, and Grossheim, i. 447, 448; Nevermann's mode of operating, i. 448; objections to these modes of proceeding, i. 448; treatment of bleeding from an intercostal artery, i. 448; wounds of the internal mammary artery, i. 449; wounds of the large vessels in the cavity of the chest speedily fatal, i. 449: stanching of bleeding from a wounded lung, i. 449; Verrey's objections to the union of penetrating wounds of the chest, i. 449; Astley Cooper on the danger attending wounds of the lungs, i. 450; Hennen on the immediate treatment of penetrating wounds of the lungs, i. 450; emphysema, i. 451; causes of emphysema, i. 451; Astley Cooper, Hennen, and South on emphysema, i. 451; the escape of air from the lungs into the cavity of the pleura, i. 451; Hennen's case of secondary emphysema, i. 451; treatment of emphysema, i. 452; Abernethy on the use of a broad chest-bandage in emphysema, i. 452; South on the practice of sucking or pumping to extract the air in the cavity of the chest, i. 452; Hennen on the healing of wounded lung, i. 452; protrusion of a portion of lung in wounds of the chest, i. 453; Hennen on the protrusion of a portion of lung, i. 453; treatment of the consecutive inflammation of the lung and pleura, i. 453; consequences of the inflammation, i. 453; Astley Cooper on the treatment of traumatic pneumonia, i. 453; wounds of the heart, i. 454; symptoms of wounds of the heart, i. 454; Speyer on the peculiar causes of death at different periods in wounds of the heart, i. 454; case of fatal wound of the heart by a broken rib, i. 454; Featherstone and Dr. Babington's cases of fatal bayonet-wound of the heart, i. 455; case of laceration of the pericardium, and superficial wound of the heart, i. 455; Hennen, Fournier, and Ploucquet's cases of foreign bodies in the heart, i. 455; treatment of wounds of the heart, i. 456; wounds of the pericardium, i. 456; Astley Cooper and Hennen's cases of wounds of the pericardium, i. 456; injuries of the gullet, thoracic duct, diaphragm, and spinal marrow, i. 456; symptoms of wounds of the diaphragm, i. 456.

CHESTON'S, Mr., case of gangrene of the bladder from retention, ii. 412.

CHEVALIER, Mr., on tying the tonsils, i. 145; case of puncturing the dura mater, to remove effused blood from beneath it, i. 407.

CHEVALIER'S, M., case of removal of the inverted womb by ligature, ii. 121.

Chiloplasty, the operation of, ii. 775.

CHILBLAINS:—i. 129, 130; symptoms and results, i. 130; Hunter mentions another inflammation very like chilblains, i. 131; seat of chilblains, i. 131; treatment, i. 131; South on the mustard liniment of St. Thomas' Hospital in the treatment of chilblains, i. 131; treatment of ulcerated chilblains, i. 131; of gangrenous chilblains, i. 131; prevention of chilblains, i. 131.

Chimney-sweep's cancer, ii. 815.

CHOPART'S, M., case of inclusion of a nerve in the noose of a ligature placed on an artery, i. 307; case of simple dislocation of the spine, i. 535; mode of operating in ovarian dropsy, ii. 487.

CHOULART, M., on the influence of spinal curvature on the transverse diameter of the pelvis, ii. 158.

CHRESTIEN, M., on gold and its preparations in primary and secondary syphilis, i. 669.

CHURCH, Mr., on tartar emetic in strangulated hernia, ii. 32.

CHURCHILL, Dr., on the treatment of lacerated perineum, i. 609.

Cirsocele, ii. 295.

CITTADINI'S, M., case of false joint, in which rubbing the ends of the broken bone together was practised, i. 590; successful operation for sawing off the ends of the broken bone, i. 594.

CIVIALE, M., on the introduction of the straight catheter, ii. 431; operations for stone on infants, ii. 569.

CLANNY'S, Dr., case of enlargement of the tongue, ii. 650.

CLARKE, Sir J. M., on the length of time during which prolapse of the womb is forming, ii. 106; on the size and shape of the prolapsed organ, ii. 106; on the consecutive ulceration of the vagina, ii. 106; case of procidentia uteri, with separation of the pelvic bones, ii. 108; on the after-treatment of procidentia uteri, ii. 109; on the application of injections, ii. 110; on the treatment of the ulcerated vagina, ii. 110; objections to sponge as a pessary, ii. 110; on the corrosion of pessaries in the passage, and on the deposit of calculous matter on them, ii. 112; on polypus of the fundus uteri as a cause of inversion, ii. 117; on the character of the discharge in inverted uterus,

ii. 119; on the treatment of chronic inversion, ii. 120; of recent inversion, ii. 120; on the diagnosis between chronic inversion and polypus uteri, ii. 120; on the treatment of the inverted womb, complicated with procidentia, ii. 121; case of removal of the inverted womb by ligature, ii. 121; on prolapse of the vagina, ii. 122; on the symptoms of prolapse of the vagina, ii. 122; on the causes and symptoms of posterior prolapse of the vagina, ii. 123; on the treatment of posterior prolapse, ii. 123.

Clarke's, Dr. J., case of removal of the inverted womb by ligature, ii. 121.

Clavicle, fracture of, i. 550; dislocation of, i. 777; resection of, ii. 1003.

Clay, Dr., on the large operation for ovarian dropsy, ii. 489.

Clement's, Mr., case of successful operation for strangulated umbilical rupture during pregnancy, ii. 82.

Cline's, Mr., experiments to cause the absorption of the pus in lumbar or psoas abscess, i. 188; on the lengthening and shortening of the diseased limb in hip disease, i. 256; experiments with the broad ligature on arteries, i. 304; case of musket-shot wound of the bladder, the ball remaining in that viscus, and being afterwards extracted by operation, i. 482; case of fracture of the spine without displacement, i. 534; case of cure of ununited fracture, i. 591; case of double umbilical rupture, ii. 80; case of the existence of several aneurisms in the same person, ii. 204; cases in which the femoral artery was tied with a broad tape, the ligature being removed some hours afterwards, ii. 222; case of obliteration of the vena cava inferior, ii. 289; case of varix of a deep-seated vein, ii. 289; on excision of piles, ii. 304; case of impending suffocation from ranula, ii. 404; case of stone in one of the submaxillary ducts, ii. 405; case of very large hydrocele, ii. 498; case of suppuration of the kidney from impaction of calculus in the ureter, ii. 544; case of large calculus, ii. 546; case of an old man operated on for stone, ii. 569; gorget, ii. 592; on the question as to the propriety of removing a scirrhous breast, ii. 796; the first experimenter with vaccine lymph, ii. 873.

Cline's, Mr., jun., cases of after-bleeding, in which the actual cautery was employed, i. 314; clinical observations on after-hæmorrhage, and on the use of the actual cautery in such cases, i. 316; experiments on arteries, i. 318; on the disposition of hydrophobic animals to use their weapons of offence, i. 369; directions for the excision of the part bitten by a mad dog, i. 373; on puncturing the brain in wounds of the dura mater, i. 399; case in which he performed the operation for trepanning the spine, i. 538; details of the case, i. 539; clinical observations on the case, i. 539; on the use of caustics to destroy the cartilaginous ends of broken bones in false joints, i. 590; case of cure of false joint by caustic potash, i. 591; reduction of an old dislocation of the humerus, i. 766; case of hydrocele in front of an inguinal rupture, ii. 61; case of aneurism of the anterior tibial artery, ii. 265; on tumours of nerves in stumps, ii. 766; case of amputation of the penis, ii. 801; on ligature of the spermatic cord, ii. 813; on arteriotomy, ii. 864.

Clitoris, enlargement of, ii. 664.

Cloquet's, M., treatment of fractured clavicle, i. 552; on the solution of the chloride of lime in the treatment of foul, gangrenous, or torpid ulcers, i. 616; on the statistics of rupture, ii. 8; explanation of the manner in which *reduction en masse* takes place, ii. 17; on the spontaneous return of the hernial sac into the abdomen, ii. 22; on Nuck's canal, ii. 65; case of lumbar rupture, ii. 84; on thyroid rupture, ii. 88; on elongation of the womb in cases of prolapse, ii. 106; on the formation of calculi in the displaced bladder, consequent on prolapsus uteri, ii. 106; on consecutive displacement of the rectum, ii. 107; case of the existence of numerous aneurisms in the same person, ii. 204.

Clossius', M., explanation of the lengthening of the limb in hip disease, i. 257.

Club foot, ii. 174.

Coates, Dr., on the application of blisters in the treatment of carbuncle, i. 138; on ligature of the common carotid, ii. 234; case in which the bronchocele ultimately enlarged, after the ligature of the superior thyroid, ii. 659.

Coccyx, fracture of, i. 543; dislocation of, i. 776.

Cock, Mr., on the reduction of the dislocated femur by placing the foot between the thighs, and making extension and rotation, i. 801; case of sixpence in the larynx, ii. 398.

Cephalæmatoma, ii. 447.

Coffinière, M., on toothache as a counter-irritant, i. 703.

Coherence, unnatural: — definition, ii. 305; causes and mode of union, ii. 305; contraction and closure of the outlets of the body, ii. 305; congenital closure of the outlets, and congenital union of parts which should be separate, ii. 306; condition of the parts when an outlet is

closed, ii. 306; treatment of parts preternaturally united, ii. 306; treatment of deforming cicatrices, ii. 306; treatment of narrowing and closure of the outlets, ii. 307; of imperforation, ii. 307; *union of the fingers and toes*, ii. 308; causes, ii. 308; the operation for its treatment, ii. 308; circumstances which contra-indicate the operation, ii. 308; after-treatment, ii. 308; result of the operation often unsatisfactory, ii. 308; mode of operating, and treatment to prevent reunion, ii. 309; Dupuytren and Rudtorffer's plans to prevent reunion, ii. 309; Zeller's operation, ii. 309; *the growing together of the joint-ends of bones, or anchylosis*, ii. 310; definition, ii. 310; sub-divisions, ii. 310; causes, ii. 310; nature of the connecting substance, ii. 310; treatment, ii. 311; Dr. Barton's operation on the anchylosed femur, ii. 311; von Wattmann's operation on the humerus in anchylosis of the elbow, ii. 311; treatment of the slighter degrees of false anchylosis, ii. 311; of the more severe forms, ii. 311; the operation in contraction of the knee-joint, ii. 312; occasional results, ii .312; *growing together and narrowing of the nostrils*, ii. 313; characters, ii. 313; the operation for contracted nostrils, ii. 313; after-treatment, ii. 313; *unnatural adherence of the tongue*, ii. 314; direct causes, ii. 314; diagnosis, ii. 314; treatment, ii. 314; of the tumour under the tongue, ii. 314; division of the frenum, ii. 314; treatment of adhesion of the tongue to the cheek, ii. 314; South on adhesion of the tongue to the cheek, ii. 315; consecutive accidents, ii. 315; hæmorrhage from the raninar artery, ii. 315; danger of suffocation from the tongue turning backwards, ii. 315; *growing together of the gums and cheeks*, ii. 315; causes, prevention, and treatment, ii. 315; *narrowing and closure of the mouth*, ii. 315; complete closure a very rare malformation, ii. 315; causes of narrowing, ii. 316; symptoms, ii. 316; treatment, ii. 316; Dieffenbach and Werneck's operations, ii. 316; treatment of narrowing of the mouth, with loss of substance of the lips, ii. 317; *narrowing of the œsophagus*, ii. 317; causes, ii. 318; consequences, ii. 318; symptoms of simple or membranous stricture, ii. 318; callous narrowing of the œsophagus, ii. 319; of scirrhous hardening, ii. 319; expansion of the walls and its causes, ii. 319; ulceration of scirrhous and callous, cartilaginous, and bony stricture, ii. 319; Meyer and Gendrin's cases of strictured œsophagus communicating with the bronchus or trachea, ii. 320; narrowing of the œsophagus from fungous growths, ii. 320; from swellings in the neighbourhood, ii. 320; symptoms of dysphagia lusoria, ii. 320; spasmodic stricture, ii. 320; angina impetiginosa, symptoms, characters, and treatment, ii. 321; prognosis in stricture of the œsophagus, ii. 321; Astley Cooper's case of stricture of the œsophagus ulcerating externally, ii. 321; treatment of stricture caused by chronic inflammation, ii. 321; introduction of the œsophageal sound, ii. 322; mode of operating, ii. 322; introduction of the sound through the nostril improper, ii. 322; use of a sound with a lead stilette, ii. 322; South's objection to the protrusion of the tongue prior to the passage of the œsophagus-bougie, ii. 323; Astley Cooper's case of stricture of the œsophagus, in which a false passage was made through into the anterior mediastinum, ii. 323; dilatation of the stricture, and subsequent treatment, ii. 323; use of caustic bougies very dangerous, ii. 323; Jameson and Fletcher's instruments, ii. 323; general treatment for callous, scirrhous, and spasmodic stricture, and for dysphagia lusoria, ii. 324; use of the œsophageal sound for the passage of strong broths, ii. 324; dysphagia paralytica atonica, ii. 324; *narrowing and closure of the rectum*, ii. 324; closure of the rectum always a malformation, ii. 325; stricture rarely congenital, ii. 325; congenital closure of the rectum, ii. 325; symptoms, ii. 325; Wolff's case of imperforate anus, ii. 325; the operation for imperforate anus, ii. 325; the operation to be performed when there is not any trace of an anus, ii. 326; Amussat's operation, ii. 326; South's case of adherence of the two portions of the ileo-colic valve, causing obstruction to the passage of the meconium, ii. 326; the operation for the rectum opening into the vagina, ii. 327; Barton and Dieffenbach's operations, ii. 327; opening of the rectum into the urethra, ii. 327; the operation, ii. 327; opening of the rectum into the urinary bladder, ii. 328; Fergusson's case of opening of the rectum into the bladder, ii. 328; Cruveilhier's case of opening of the rectum under the glans penis, ii. 328; the formation of an artificial anus at the lower end of the colon, ii. 328; the mode of operating, ii. 328; Callisen and Amussat's mode of operating, ii. 328; Pilore's case, in which he made an artificial anus in the right side, by opening the cæcum, ii. 328; Freer and Pring's cases of operation for artificial anus at the lower end of the colon, ii 329; congenital narrowing of the anus, ii. 329; South's case of im-

perforate anus, opening under the glans penis, ii. 329 ; stricture of the rectum, ii. 330 ; spasmodic contraction of the anus, ii. 330; causes, ii. 330 ; symptoms, ii. 330 ; examination of the anus, ii. 331 ; fissure of the rectum, ii. 331 ; Brodie on ulceration of the rectum in connexion with spasmodic contraction of the sphincter, ii. 331 ; Bushe on the spasmodic contraction of the anus, ii. 331 ; spasmodic contraction distinguished from narrowing, ii. 331 ; treatment, ii. 331 ; division of the sphincter, ii. 332 ; after-treatment, 333 ; narrowing of the rectum, depending on chronic inflammation, ii. 333 ; characters, ii. 333 ; progress and terminations of the disease, ii. 334 ; local results of stricture, ii. 334 ; Brodie on the occurrence of symptoms of strangulated hernia in some cases of stricture, ii. 334 ; Astley Cooper's case of stricture of the rectum, ii. 334 ; changes produced in the tissues of the gut by chronic inflammation, ii. 334 ; Brodie on the post-mortem appearances in stricture of the rectum, ii. 334 ; Lawrence on the spongy excrescence of the rectum, ii. 335 ; situation of the stricture, ii. 335 ; excrescences growing from the valvulæ conniventes, ii. 335 ; examination of the rectum for stricture, ii. 335 ; Lawrence and Bushe on stricture of the rectum, ii. 336 ; White, Salmon, Charles Bell, Colles, Allan, Liston, Syme, Brodie and Bushe on the seat of stricture in the rectum, ii. 336 ; immediate cause of stricture, ii. 337 ; prognosis, ii. 337 ; Brodie on the necessity of early treatment in stricture of the rectum, ii. 338 ; treatment, ii. 338 ; Brodie on the distension of the bowel above the stricture by fæces, ii. 338 ; stretching the contracted part, ii. 338 ; introduction of bougies, ii. 338 ; Brodie and Lawrence on the use of bougies, ii. 339 ; Brodie on the internal application of mercurial ointment in stricture of the rectum, ii. 340 ; dilatation by prepared gut, and by metallic dilators, ii. 340 ; incision of the stricture, ii. 340 ; Copeland and Brodie on incision of the stricture, ii. 340 ; extirpation of tuberculous excrescences, ii. 341 ; use of the caustic bougie, ii. 341 ; treatment of fistulæ complicating the stricture, ii. 341 ; of cancerous stricture, ii. 341 ; operation for the removal of cancerous stricture, ii. 341 ; stricture caused by a cicatrix, ii. 342 ; narrowing of the anus from union between the nates, ii. 342 ; treatment of closure of the rectum from stricture, ii. 342 ; *growing together, and unnatural closure of the prepuce*, ii. 342 ; phimosis and paraphimosis, ii. 343 ; phimosis congenital or acquired, ii. 343 ; consequences, ii. 343 ; after puberty, ii. 343 ; causes of accidental phimosis, ii. 343 ; symptoms, ii. 344 ; consequences of venereal ulcers on the corona glandis, complicated with phimosis, ii. 344 ; treatment of phimosis, ii. 344 ; operations by circumcision and slitting up the prepuce, with or without removal of the flaps, ii. 344 ; circumcision, ii. 344 ; the Jewish operation, ii. 345 ; South on the Jewish operation, ii. 345 ; slitting up the prepuce, ii. 345 ; after-treatment, ii. 346 ; the preference given to the latter operation, ii. 346 ; division of the inner fold of the prepuce, ii. 346 ; Langenbeck, Begin, and Vidal de Cassis' operations, ii. 347 ; treatment of phimosis complicated with union, partial or complete, of the prepuce to the glans, ii. 347 ; connexion of the glans with the prepuce by bands, ii. 347 ; treatment of phimosis from inflammation, ii. 348 ; from excoriation or putrefaction of the cheese-like matter, ii. 348 ; treatment of syphilitic phimosis, ii. 348 ; Pigné on the treatment of syphilitic phimosis, ii. 348 ; the operation rarely required for inflammatory and venereal phimosis, ii. 348 ; the introduction of the catheter requisite, when the issue of the urine is impeded by the constriction of the phimosis on the urethra, ii. 349 ; the origin and symptoms of paraphimosis, ii. 349 ; treatment, ii. 349 ; reduction of the prepuce, ii. 349 ; treatment of the accompanying inflammation, ii. 349 ; South on the reduction of paraphimosis, ii. 350 ; the operation for paraphimosis, ii. 350 ; treatment if suppuration have occurred, ii. 351 ; after-treatment, ii. 351 ; constriction of the penis by threads, tape, rings, &c., ii. 351 ; symptoms and treatment, ii. 351 ; *narrowing and closure of the urethra*, ii. 351 ; stricture of the urethra of more frequent occurrence than in any other outlet, ii. 352 ; symptoms, ii. 352 ; Brodie on incontinence of urine in stricture, ii. 352 ; extravasation of urine from rupture or sloughing of the urethra behind the stricture, ii. 353 ; Brodie on extravasation of urine from ruptured urethra in stricture, ii. 353 ; Brodie on abscesses communicating with the bladder in old cases of stricture, ii. 353 ; changes in the urethra in old strictures, and the attendant symptoms, ii. 353 ; Brodie on the complication of stricture with enlarged prostate, ii. 354 ; Brodie's case of enlargement of the urethra from stricture, ii. 354 ; Brodie on the formation of cysts of the urethral mucous membrane in stricture, ii. 354 ; Brodie on the occurrence of rigors and fever in cases of stricture, ii. 354 ; causes of stricture, ii. 355 ; Brodie on the existence in old strictures of an indurated mass at the lower portion of the penis, ii. 355 ;

seat and characters of stricture, ii. 355; Hunter's description of three forms of stricture, ii. 356; Brodie on the original seat of stricture, ii. 356; diseases liable to be confounded with stricture, ii. 356; diagnosis, ii. 357; prognosis, ii. 357; treatment ii. 357; mode of determining the seat of the stricture, ii. 357, 358; Brodie on the use of a full-sized bougie in determining the seat of the stricture, ii. 357; preparation of common bougies, ii. 358; Astley Cooper, Abernethy and Brodie on the passing the bougie, ii. 359; Astley Cooper and Abernethy on the use of metallic bougies, ii. 359; Brodie on the treatment of stricture with bougies, and on their applicability to the respective kinds of stricture, ii. 360; Brodie's directions for the introduction of the bougie, ii. 360; South on the danger of using plaster bougies, ii. 361; South on the introduction of the bougie, ii. 362; South on the general treatment of stricture, ii. 363; the time the bougie should be left in the urethra, and the frequency of its introduction, ii. 363; precautions to be taken when the instrument is left in the urethra, ii. 364; gradual increase in the size of the instrument used, ii. 364; Arnott's oil-silk tube, ii. 364; action of the bougie, ii. 364; symptoms occasionally produced by it, ii. 364; Astley Cooper and Abernethy on hæmorrhage from the urethra after passing the bougie, ii. 365; Astley Cooper and South on the practice to be adopted when a laceration of the urethra by the bougie is suspected, ii. 365; destruction of the stricture by caustic, ii. 365; by ulceration to be rejected as dangerous, ii. 365; Brodie on the destruction of stricture by ulceration, ii. 365; cauterizing a stricture from before backwards, ii. 366; preparation of armed bougies, ii. 366; Hunter, Home and Whately on the use of the armed bougie, ii. 366; objections to this mode of cauterization, ii. 366; cauterizing the walls of the stricture, ii. 366; Whately and Arnott on cauterizing the walls of the stricture, ii. 367; use of bougies armed with caustic potash, ii. 367; Whately and Lawrence on the use of bougies armed with caustic potash, ii. 368; Ducamp's mode of cauterizing the urethra, ii. 368; subsequent treatment, ii. 369; Ducamp's mode of dilating the urethra after cauterization, ii. 369; Ducamp's caution respecting the use of caustic, ii. 370; Lallemand, Segalas and Tanchou's caustic-holders, ii. 370; relative advantages of the treatment by bougies and by caustic, ii. 370; Astley Cooper, Brodie, Lawrence and South on the use of the armed bougie, ii. 371; cutting into the stricture, and subsequent dilatation, ii. 372; Jameson's treatment of stricture, ii. 372; formation of false passages, ii. 373; treatment, ii. 373; South on the treatment of false passages, ii. 373; congenital closure of the urethra, ii. 373; treatment, ii. 373; *hypospadias* and its treatment, ii. 374; *closure and narrowing of the vagina*, ii. 374; congenital or accidental, ii. 374; symptoms of congenital closure of the vagina, ii. 374; narrowing of the vagina, ii. 375; treatment, ii. 375; operation for complete closure of the vagina by the hymen, ii. 375; division of the united labia, ii. 375; South on the treatment of closed vagina in infants, ii. 375; the closure more or less deep in the vagina, ii. 376; complete closure of the vagina without signs of menstruation, ii. 376; partial closure or bands of the vagina, ii. 376; Locock's case of bands in the vagina from previous difficult labour, ii. 376; Kennedy and Labat's cases, ii. 376; treatment of narrowing of the vagina, ii. 376; treatment after the escape of the retained catamenia, ii. 377; *closure and narrowing of the mouth of the womb*, ii. 377; congenital or acquired, ii. 377; characters ii. 377; consequences of the retention of the catamenia, ii. 377; treatment by operation, ii. 377; after-treatment, ii. 378; operation for closure of the os uteri from scirrhous degeneration, ii. 378; the operation when the os uteri is completely closed, or cannot be felt, ii. 378.

COLE'S, Mr., mode of amputating at the hip-joint by the circular cut, ii. 934.

COLLES, Mr., on the ingrowing of the nail, i. 199; on the disease of the nail liable to be mistaken for gout, i. 199; condemns Cooper's operation for ingrowing of the nail, i. 201; operation for the treatment of that disease, i. 201; on onychia maligna, i. 202; plan of treatment, i. 203; doubts whether a syphilitic infant can infect its nurse, unless she have ulceration of the nipple, i. 673; case of ligature of the subclavian above the clavicle, ii. 243; on the seat of stricture in the rectum, ii. 336.

COLOMBAT'S, M., mode of reduction of dislocated femur, i. 800; hysterotome, ii. 822.

COLOMBE'S, M., experiments respecting staphyloraphy on the dead body, i. 603.

CÔME'S, FRÈRE, operation with the *lithotome caché*, ii. 595.

COMPRESSION; PRESSURE ON THE BRAIN, i. 404; causes, i. 404, 405; symptoms, i. 404; Guthrie on stertor an uncertain sign of compression, i. 404; Guthrie on a peculiar whiff or puff from the corner of the mouth a sign of compression, i. 404; prognosis, i. 405; treatment, i. 405; South on mercury in compression, i. 405; removal of extravasated blood either by absorption or trepanning, i. 405; signs indicative of the propriety of trepanning, i. 405; removal of the extravasation after the performance of the operation, i. 406; South on the removal of the extravasated blood after the operation, i. 406; South, Pott and Brodie on puncturing the dura mater, when the extravasation lies beneath it, i. 406; Pott on the extravasation between the meninges, or on the surface of the brain, i. 406; Chevalier and Ogle's cases, i. 407; Hunter, Astley Cooper, Abernethy and Lawrence on puncturing the dura mater to evacuate the effused blood, i. 407; South on the operation of trepanning to remove effused blood, i. 408.

Concussion of the Brain, i. 408; symptoms, i. 408; Astley Cooper and South on the state of the pulse in concussion, i. 409; Astley Cooper and Larrey's cases of loss of memory, &c., after concussion, i. 409; Hennen on the loss of certain faculties from concussion, i. 409; Astley Cooper on the condition of the alimentary canal and bladder during concussion, i. 409; the diagnosis of concussion from compression, i. 409; concussion and compression may occur together, i. 410; difficult to distinguish between drunkenness and concussion or compression, i. 410; in drunkards delirium tremens may succeed concussion, i. 410; inflammation of the brain may be connected with concussion, i. 410; primary and consecutive changes in the brain from concussion, i. 410; Dupuytren distinguishes between commotion and contusion of the brain, i. 410; Walther and Astley Cooper on the symptoms of laceration of the brain, i. 410; Astley Cooper on the condition of the brain in moderate concussion, i. 410; causes of concussion, i. 411; Astley Cooper on the causes of concussion, i. 411; Schmucker's case of concussion, i. 411; prognosis, i. 411; treatment, i. 411; South on the treatment of concussion, i. 411; Astley Cooper's case of enormous blood-letting in concussion, i. 412; after-treatment, i. 412.

Cook's, Dr., case of fistulous opening in the stomach, i. 477.

Cooper, Sir Astley, on the effects of frostbite, i. 127; observations on the effects of too suddenly warming a frozen or benumbed limb, i. 129; on the danger of carbuncle on the head and neck, i. 137; on incisions in carbuncle, i. 138; did not consider any benefit was derivable from the excision of the relaxed uvula, i. 147; on chronic abscess of the breast, i. 153; on the treatment of fissured nipples, i. 154; on the period when gonorrhœa first shews itself after infection, i. 156; on the primary symptoms of gonorrhœa, i. 156; on the actual seat of the discharge, i. 156; on the post-mortem appearances in gonorrhœa, i. 157; on the occurrence of hæmorrhage in severe gonorrhœa, i. 157; on the influence of constitutional causes on gonorrhœa, i. 159; on the sympathetic bubo of gonorrhœa, i. 167; on the treatment of gonorrhœa, i. 170; observes that gonorrhœa is difficult to cure in strumous subjects, i. 170; on the remedies for chordee, i. 170; on gleet and its infectious nature, i. 173; on the distinction between gonorrhœa or gleet, and abscess of the lacunæ, i. 173; on the treatment of gleet, i. 173; on the use of cubebs in gonorrhœa, i. 175; on syphilitic swelling of the testicles, i. 178; mentions enlargement of the prostate in old age, inflammation of the neck of the bladder, a stone passing through the ureter, or pressing on the commencement of the urethra from the bladder, as causes of swelled testicle, i. 178; on the symptoms and progress of orchitis, i. 179; on adhesion and thickening of the tunica vaginalis, i. 179; on suppuration of the testicle, i. 180; on wasting of the testicles, as caused by inflammation, i. 180; on the more frequent seat of the disease in the globus major, i. 180; on the symptoms of psoas abscess, i. 185; on the origin of psoas and lumbar abscess in inflammation of the spine and inter-vertebral substance, i. 186; remarks that lumbar abscess must be allowed to take its course, i. 188; this opinion controverted by South, i. 188; recommends Abernethy's plan of treatment, i. 190; on the treatment of the sinuous cavities resulting from lumbar abscess by injections, i. 191; says the application of a blister will often bring away the nail in cases of its ingrowing, i. 200; this opinion contravened by South, i. 200; operation for the removal of the diseased portion of nail, i. 200; condemned by Colles and South, i. 201; on the removal of the nail with its secreting surface in onychia maligna, i. 203; on gonorrhœal rheumatism and ophthalmia, i. 217; case of gonorrhœal rheumatism and ophthalmia, i. 217; on the second stage of hip-disease, i. 252; on the bursting of abscesses of the hip-joint, i. 253; on the lengthening of the limb from effusion into the joint, i. 258; on morbus coxæ senilis, i. 262; on the manner in which vertebral caries is cured by anchylosis, i. 283; on vertebral caries in the neck, i. 284; on the union of wounds, i. 289; on adhesive inflammation, i. 290; on the catgut ligature, i. 307; case of accidental torsion, i. 311; on the application of a ligature above a viper's bite, i. 354; on fracture of the frontal sinuses, i. 392; on apparent fracture and depression of the skull, i. 392; on the treatment of simple fracture with depression without the trephine, i. 392; on the necessity for raising or removing the depressed bone in compound fracture, i. 394; case of lodgment of a ball in the frontal sinuses, i. 395; case of fatal perforation of the orbitar plate of the frontal bone, i. 396; on the removal of foreign bodies in injuries of the brain, i. 398; on puncturing the brain in wounds of the dura mater, i. 399; case of chronic inflammation of the dura mater, i. 400; on puncturing the dura mater to evacuate effused blood, i. 407; on the state of the pulse in concussion, i. 409; cases of loss of memory, &c., after concussion, i. 409; on the condition of the alimentary canal and bladder during concussion, i. 409; on the symptoms of laceration of the brain, i. 410; on the condition of the brain in moderate concussion, i. 410; on the causes of concussion, i. 411; case of enormous bloodletting in concussion i. 412; only employs trepanning in injuries of the head when secondary symptoms of irritation and pressure require it, i. 412; case of suspended intellect, the consequence of an injury to the head, cured by the application of the trephine i. 418; on wounds of the throat, i. 431; case of fistulous opening in the thyroid cartilage, i. 434; objection to the use of the œsophagus-tube, i. 435; on the signs of wounded lung, i. 440; case of wound of the intercostal muscles by an iron spindle, i. 443; on the danger attending wounds of the lungs, i. 450; on emphysema, i. 451; on the treatment of traumatic pneumonia, i. 453; case of wound of the pericardium, i. 456; mode of practice in small wounds of the intestines, i. 469; on stabs of the liver, i. 478; case of wound of the spleen, i. 479; cases of separation of the spleen from its attachments, i. 480; on wounds of joints, and their results, i. 489; treatment of wounded joints by a fine suture, i. 490; on the effect of compound fractures on the constitution, and the reduction of a compound to a simple fracture, i. 510; on dressing the wound in compound fracture, i. 514; on the union of compound fractures, i. 515; on the question of immediate amputation, i. 518; considers simple dislocation of the spine to be of very rare occurrence, i. 534; says fracture with displacement above the fourth cervical vertebra is immediately fatal, i. 536; on softening of the spinal cord after a severe blow, i. 537; on the operation for trepanning the spine, i. 538, 540; on fracture of the anatomical neck of the humerus, i. 553; on fracture of the surgical neck, i. 554; on the union of fracture of the condyles of the humerus, i. 557; apparatus for fractured clavicle, i. 560; first describes fracture of the coronoid process of the ulna, i. 561; on its union by ligament, i. 562; on the distinction between fracture of the neck of the femur within and without the capsular ligament, i. 564; on the in-locking of the broken ends of the bone, i. 564; on inversion of the foot, i. 565; on interstitial absorption in the neck of the femur, i. 566; admits bony union in fractures external to, but not in fractures internal to, the capsular ligament, i. 566; on the treatment of fractures of the neck of the femur, i. 570; bandage for the treatment of oblique fracture through the trochanter major, i. 572; on the bent position in fracture of the femur, i. 574; apparatus for fracture of the patella, i. 579; on the causes of the non-union of fractured bones, i. 588; on salivary calculi, i. 715; case of artificial anus in the jejunum terminating fatally, i. 718; case of fistula in ano, i. 727; on the impropriety of operating for fistula in phthisical subjects, i. 728; on dressing the wound after the operation, i. 731; on the treatment of callous urinary fistula, i. 740; on the suture of urethral fistula, i. 741; on urethroplasty, i. 742; operation for recto-urethral fistula, i. 748; cases of dislocation from a lax condition of the ligamentous capsules of the joints, i. 764; on laxity of the ligaments of the lower jaw, i. 772; on dislocation of the costal cartilages, i. 777; on the symptoms of dislocation of the sternal end of the clavicle backwards, i. 778; on a partial dislocation of the humerus, i. 781; case of reduction of an old dislocation of the elbow, i. 790; mode of reduction in dislocations of the elbow, i. 790; on dislocation of the upper end of the radius forwards, i. 791; on the difficulty attending the reduction of this dislocation, i. 792; on the cause of the difficulty experienced in reducing the dislocation of the thumb from the metacarpal bone, i. 794; on the relative frequency of dislocations of the femur, i. 795; on the reduction of dislocation of the femur downwards, i. 801; on dislocation of the semilunar cartilages, i. 806; cases of dislocation of the great cuneiform bone, i. 813; case of dislocation of the toes, i. 814; on the double hernial sac, ii. 4; on the nature of strangulation, ii. 11; on the complication of strangulated hernia by the presence of an irreducible rupture, ii. 13; case in which the entire hernial sac was ineffectually removed, ii. 29; objections to ligature of the sac, ii. 29; case of sloughing of the omentum, ii. 41; on the operation of dilating the abdominal ring, the hernial sac not being opened, ii. 43; reasons for recommending the operation of dividing the stricture without opening the sac, in large and old ruptures, ii. 43; case of sloughing of the intestine after it had been returned into the abdomen, ii. 49; case of tetanus after the operation for strangulated hernia, ii. 51; on encysted hernia of the tunica vaginalis, ii. 59; on the seat of femoral rupture, ii. 70; on the presence of other tumours in the femoral region, liable to be mistaken for femoral rupture, ii. 70; on the varieties of femoral rupture, ii. 75; case of umbilical rupture, in which the sac was either absorbed, or burst, ii. 80; on the occasional enormous size of umbilical rupture in women, ii. 80; on the danger of sloughing of the integuments in strangulated umbilical rupture, ii. 82; on suppuration of the omentum in strangulated umbilical rupture, ii. 82; case of successful operation for strangulated umbilical rupture during pregnancy, ii. 82; opposed to the radical cure of reducible umbilical rupture by ligature, ii. 83; on the operation for strangulated ischiatic rupture, ii. 87; on the operation for strangulated thyroid rupture, ii. 89; on pudendal hernia, ii. 91; case of phrenic rupture, depending on malformation of the diaphragm, ii. 92; on internal strangulation, ii. 94; case of aneurism mistaken for abscess, ii. 202; on the age at which aneurism occurs, ii. 203; on the relative frequency of aneurism in the sexes, ii. 203; cases of several aneurisms in the same person, ii. 204; on the effects produced by the ligature on the arterial coats, ii. 219; case in which Brasdor's operation was performed, ii. 230; case of ligature of the common carotid, ii. 233; on the impediment to ligature of the common carotid offered by the internal jugular vein, ii. 235; on the post-mortem appearances in a case in which he had tied the common carotid 13 years previously, ii. 236; case of aneurism of the posterior aural, ii. 240; case of ligature of the subclavian above the clavicle, ii. 243; on spontaneous aneurism of the brachial, ii. 251; on ligature of the arteries of the fore-arm, ii. 251; case of ligature of the aorta, ii. 254; case of ligature of the external iliac in the groin, ii. 259; on ligature of the external iliac, ii. 261; on the post-mortem appearances after ligature of the external iliac, ii. 262; case of aneurism of the anterior tibial, ii. 265; on the treatment of aneurism of the anterior tibial low down in the leg, by opening the sac, and tying the artery above and below, ii. 265; on the post-mortem appearances after ligature of the femoral, ii. 267; on the treatment of aneurismal varix, ii. 271; on the causes of varicocele, ii. 296; operation for varicocele, ii. 297; on the excision of piles, ii. 304; case of stricture of the œsophagus ulcerating externally, ii. 321; case of stricture of the œsophagus in which a false passage was made through into the anterior mediastinum, ii. 323; case of stricture of the rectum, ii. 334; on the passing a bougie in stricture of the urethra, ii. 359; on the use of metallic bougies, ii. 359; on hæmorrhage from the urethra after passing the bougie, ii. 365; on the practice to be adopted when a laceration of the urethra by bougie is suspected, ii. 365; on the use of the armed bougie, ii. 371; case of a ball lodged in the frontal sinus, ii. 380; case of fish-bone at the glottis, ii. 384; on chronic enlargement of the prostate, ii. 422; on the symptoms and post-mortem appearances of chronic enlargement of the prostate, ii. 423; on the characters of enlarged prostate, ii. 423; on the treatment of enlarged prostate, ii. 424; on the treatment of retention of urine from enlarged prostate, and on catheterism in such cases, ii. 425: case of hæmatocele, ii. 456; case of hæmatocele of 17 years duration, ii. 456; on puncturing in spina bifida, ii. 468; on tapping in the linea alba, ii. 483; case of spontaneous rupture of the ovarian cyst, ii. 491; case of ovarian dropsy in which the fluid was discharged by ulceration of the navel, ii. 492; case of hour-glass hydrocele, ii. 497; on the situation of the testicle in hydrocele, ii. 498: on the characters of the serum in hydrocele, ii. 498; on the spontaneous cure of hydrocele, ii. 499; on the radical cure of hydrocele by exercise after tapping, ii. 501; on the cause of the failure of injection to cure the disease, ii. 504; cases of foreign bodies the nuclei of stones, ii. 524; case of renal calculus, ii. 541; case of renal calculus communicating with abscess in the loins, ii. 542; case of suppuration of the kidney from impaction of calculus in the ureter, ii. 544; on the treatment of calculi in the ureters, ii. 544; case of large calculus, ii. 546; case of a great number of calculi in the bladder, ii. 547; on the dilatation of the female urethra, ii. 556; case of an old man operated on for stone, ii. 569; on the section of the prostate, ii. 590; on opening the membranous part of the urethra, ii. 592: on the symptoms of stone in women, ii. 617: case of ulceration of the bladder and vagina by the pressure of a large stone, ii. 617; on the incontinence of urine consequent on lithotomy in women, ii. 621; case of prostatic stone, ii. 634; case, in which lithectasy was performed, ii. 643; case of enlargement of the nymphæ, ii. 665; case of human horns, ii. 670; case of very large fatty tumour, ii. 691; opinion that fatty tumours sometimes take on a malignant degeneration, ii. 693; on cellular hydatids of the breast, ii. 696; on sebaceous tumours, ii. 697, 698; on the cause of sebaceous tumours, ii. 698; case of cellular membranous tumour, ii. 711; on medullary fungus of bone, ii. 718; case of tumour in the popliteal nerve, ii. 765; on tumours on nerves in stumps, ii. 765; on fungous degeneration of the nipple of the breast, ii. 786; on the development of the nipple in the fœtus, and its subsequent changes, ii. 786; on hydatid swellings of the breast, ii. 791; on the symptoms and treatment of cellulous hydatids of the breast, ii. 791; on polypoid hydatids of the breast, ii. 792; on globular hydatids of the breast, ii. 792; on the question as to the propriety of removing a scirrhous breast, ii. 796; on the nature of the cysts in cystic swelling of the testicle, ii. 809; on the retraction of the cord during the extirpation of the testicle, ii. 812; cases of chimney-sweep's cancer in the cheek, ii. 816; case of excision of a portion of the radial nerve, ii. 887; mode of amputating at the shoulder-joint with a single flap, ii. 956; case of amputation at the shoulder-joint, ii. 961; mode of extirpating the metacarpal bones of the middle and ring fingers, ii. 965; case of excision of part of the hand, ii. 965; opinion in favour of immediate amputation in severe injuries of the lower extremities, the constitution then having only one shock to sustain, ii. 967; case of excision of the lower jaw, ii. 988.

Cooper's, Mr. Bransby, case of reduction of an old dislocation of the elbow, i. 790; on dislocation of the upper end of the radius forwards, i. 791; on the double hernial sac, ii. 4; case of reduction *en masse*, ii. 17; case in which Gerdy's operation for the radical cure of rupture was performed, ii. 25; case of simple serous cysts of the neck, ii. 695; case of entrance of air into a vein, ii. 856.

Cooper's, Mr. Samuel, case of orchitis simulating strangulated rupture, i. 180; mentions Mr. Ramsden's case of lumbar abcess, i. 187; on the substance which fills up the acetabulum in secondary dislocation in hip disease, i. 259; on secondary hæmorrhage in gun-shot wounds, i. 341; case of chronic tetanus of five weeks' duration, i. 378; on the causes of tetanus, i. 379; cases of prolapsed womb in virgins, ii. 107; on the effects of compression in aneurism, ii. 214.

Cooper's, Mr. William, case of radial aneurism, ii. 251.

Copeland's, Mr., objection to stuffing the rectum in cases of hæmorrhage after the operation for rectal fistula, i. 731; operation for recto-vaginal fistula by the division of the sphincter ani, i. 761; on prolapse of the internal membrane of the rectum, ii. 130; on the diagnosis between prolapsed rectum and hæmorrhoids, and intus-susception, ii. 131; operation for prolapse of the rectum, ii. 135; on the removal of internal piles by ligature, ii. 302; on the application of the ligature, ii. 303; on the incision of the stricture in stricture of the rectum, ii. 340; case of very large fatty tumour, ii. 691.

Copland, Dr., on the asthenic boil, i. 133; on anthrax, i. 136; diagnostic sign for vertebral caries, i. 281; on puncturing the brain in chronic hydrocephalus, ii. 467; on the age at which bronchocele most usually occurs, ii. 655.

Coracoid process, fracture of, i. 549.

Corns, ii. 668.

Cornuau's, M., mode of amputating at the hip-joint, ii. 940; at the knee with the circular cut, ii. 944; at the shoulder-joint with the circular cut, ii. 958; mode of operating in exarticulation of the fore-arm at the elbow, ii. 962.

Cortez, M., on the treatment of hæmorrhage consecutive on the extraction of a tooth, i. 709.

Cotton's, Dr., case of injurious effects produced by inhalation of ether, ii. 1008.

Coulson's, Mr., case of hysterical affection of the joints, i. 250; on the symptoms of this disorder, i. 250; explanation of the pain on the inside of the knee in hip disease, i. 252; on the bursting of abscesses of the hip-joint, i. 253; on dislocation into the foramen ovale in hip disease, i. 259; on the diagnosis between hip disease in the third stage, and psoas abscess, i. 260; on salt water bathing in hip disease, i. 263; case of closure of the rectum from the presence of a foreign body, ii. 393.

Coxalgia, inflammation of the hip-joint, i. 250; the three stages of the disease, i. 250; symptoms of acute inflammation of the hip-joint, i. 251; Key on the greater frequency of chronic than of acute inflammation of the hip-joint, i. 251; symptoms when suppuration takes place, i. 251; symptoms of the first stage of chronic inflammation of the hip-joint, i. 251; Brodie on ulceration of the cartilage, the primary affection in diseased hip, i. 252, 261; Key's opinion that the ulceration of the cartilages is preceded by inflammation of the ligamentum teres, i. 252, 261; South on the pain on the inside of the knee in hip disease, i. 252; Bell and Coulson's explanation of that symptom,

i. 252; symptoms of the second stage of chronic inflammation of the hip-joint, i. 252; Astley Cooper on the second stage of hip disease, i. 252; Key on the symptoms which indicate the special part of the joint affected, i. 253; symptoms of the third stage, i. 253; Fricke's method of examining the length of the limb during the progress of the disease, i. 253; Astley Cooper and Coulson on the bursting of abscesses of the hip-joint, i. 253; Dr. Mackenzie and Scott's cases of abscesses of the hip-joint, i. 254; Brodie on the difference between hip disease from ulceration of the cartilage, and that from scrofulous deposit in the cancellous structures of the bones, i. 254; shortening and lengthening of the diseased limb, i. 255; Hunter on these symptoms, i. 255; Cline and Lawrence on these symptoms, i. 256; the shortening only apparent, i. 256; Rust and Fricke's explanation incorrect, i. 256; South on the shortening of the limb, i. 256; the lengthening of the limb may be either seeming or real, i. 256; explanation of the lengthening of the limb by Petit, Camper, Valsalva, Monro, Van der Haar, de Haen, Vermandois, Schwenke, Callisen, Plenck, Portal, Ficker, Duverney, Clossius, Boyer, Falconer, Rust, Langenbeck, Richter, Schreger, Larrey, Chelius, Fricke, Brodie, and Crowther, i. 257; Weber's experiments show that the head of the thigh-bone is retained in the socket by atmospheric pressure, i. 257; these experiments of great importance in reference to diseases of the hip-joint, i. 257; South's explanation of the lengthening of the limb, i. 257; Astley Cooper on the lengthening of the limb from effusion into the joint, i. 258; Lawrence on the lengthening of the limb, i. 258; dislocation of the head of the thigh-bone, i. 258; Nester, Van der Haar, Berdot, Schreger, and Textor on the dislocation of the head of the thigh-bone downwards and inwards, i. 258; Hoffman's case of separation of the head of the femur, and its removal by the surgeon, i. 258; South on the appearances after death in hip disease, i. 258; Earle on dislocation into the ischiatic notch, i. 258; Boyer, Brodie, and Coulson on dislocation into the foramen ovale, i. 259; Ducros jun. on dislocation forwards on the share-bone, i. 259; the formation of a new socket, i. 259; Samuel Cooper on the substance which fills up the acetabulum, i. 259; diagnosis of coxalgia from congenital luxation of the thigh, shortening of the extremity from recession and twisting of the hip-bone, nervous sciatica, and malum coxæ senile, i, 259; coxalgia cannot well be confounded with phlegmasia alba dolens, psoas abscess, or primitive dislocation of the thigh, i. 260; may be confounded with fracture of the neck of the thigh-bone under certain circumstances, i. 260; Bell on the pain in hip disease, i. 260; South on the sympathetic pain in the hip from disordered bowels, i. 260; South, Smith, Wernherr, Astley Cooper, and Charles Bell on the morbus coxæ senilis, i. 260; Coulson on the diagnosis between hip disease in the third stage, and psoas abscess, i. 261; post-mortem appearances, i. 261; post-mortem appearances in William Adams' case, i. 262; etiology of hip-joint disease, i. 262; Fricke on the distinction between coxalgy and coxarthrocacy, i. 262; prognosis always unfavourable, i. 262; treatment, i. 262; in the first stage of acute coxalgia, i. 262; treatment of chronic coxalgia, i. 263; Nicolai and Klein recommend the use of the apparatus for fractured neck of the femur, i. 263; Physick on the treatment of coxalgia, i. 263; Scott's plan of treatment, i. 263; Lawrence's observations on the plan of treatment advocated by Scott, i. 264; has been employed by Fricke with advantage, i. 264; treatment of the second stage, i. 265; application of the actual cautery, i. 265; Rust objects to the use of issues, i. 265; approved of by South, i. 265; the actual cautery or burning cylinders preferable in all cases where the limb is much lengthened, the muscles relaxed, and where there is great swelling from collection of fluid, i. 265; Volpi has not found benefit from the actual cautery, when the first symptoms of disease occurred in the knee, and not at the hip-joint, i. 265; Brodie on the influence of the primary irritation of the issue, and on the maintaining it by repeated applications of caustic potash or sulphate of copper, i. 265; approved of by South, i. 266; Duval's local steam-bathing apparatus, i. 266; Brodie on the use of a seton in the groin, i. 266; results of the treatment, and management of convalescence, i. 266; Rust and Brodie on warm bathing, i. 267; Fritz, Rust, and Jaeger on the mercurial treatment, i. 267; Brodie on the importance of rest and position, i. 267; general treatment in the first two stages of coxalgy, i. 267; Jaeger, Rust, Dieffenbach, and Frank on the general treatment of coxalgy, i. 267; Fricke's plan, i. 267; treatment of the consecutive dislocation, i. 268; reduction of the dislocation frequently not successful, i. 268; views of Petit, Callisen, and Jaeger on the reduction of consecutive dislocation, i. 268; cases by Berdot, Hagen, Ficker, Thilenius, Mozilewsky, Schneider, B. Heine, F. Humbert, M. N. Jacquier, Textor, Volpi, Schreger, von Winter, Harless, Fricke,

and J. Heine, i. 268; treatment of suppuration, i. 269; the abscesses to be freely opened, i. 269; Ford, Wend, Van der Haar, Rust, Brodie, and Jaeger on the treatment of these abscesses, i. 269; Sabatier and Ficker advise their being opened with caustic, i. 269; Larrey, with the red-hot trocar, i. 269; Rust, with the actual cautery, i 269; Rust advises passing a seton through the joint, i. 269: Brodie and Jaeger recommend free incisions in opening these abscesses, i. 269; Brodie and South on the management of abscesses at the hip, i. 269; subsequent treatment, i. 269; resection of the carious head of the thigh-bone, i. 269; excision of the head of the femur recommended by Jaeger, Kirkland, Richter, and Vermandois, i. 270; performed by White and Hewson, i. 270; Kerr and Baffos exarticulated the thigh-bone, i. 270; Charles Bell's proposition, i. 270; Barry's case of accidental reduction of the dislocation, i. 270.

Coxe, Mr., on the treatment of vesico-vaginal fistula, by drawing off the urine, and by compression, i. 752.

Coze, M., on twisting round of the patella, i. 805.

Cramer's, M., treatment of fistulous passages, i. 93.

Crampton's, Sir **Philip**, experiments on the ligature of arteries, i. 303; on compression in the treatment of aneurism, ii. 213; case of aneurism in which the temporary ligature was employed, ii. 222; operation for ligature of the common iliac, ii. 256; on the application of leeches to mucous surfaces, ii. 865; on the excision of joints, ii. 970; recommends the non-division of the ulnar nerve in excision of the elbow-joint, ii. 975; case of excision of the elbow-joint, ii. 976.

Crisp's, Mr., case of a piece of broken catheter in the bladder, ii. 417; case of fracture of a renal calculus by sudden exertions, ii. 542.

Croix, M. **La**, **d'Orléans'**, case of amputation at the hip-joint, ii. 933.

Croserio's, M., modification of the operation for salivary fistula, i. 714.

Crosse, Mr., on the characters of the respective varieties of inversion of the womb, ii. 116; on the successive steps of the inverting process, ii. 116; on the concavity formed in all cases of inversion, ii. 117; on polypus of the fundus uteri as a cause of inversion, ii. 117; on the presence of coagulated blood, hydatids, and moles in the womb, as causes of inversion, ii. 118; on the spontaneous breaking up of calculi in the bladder, ii. 548.

Crowther, Mr., on tapping lumbar or psoas abscess with a trocar, i. 189; on the lengthening of the limb in hip disease, i. 257.

Cruveilhier, M., on phlebitis, i. 77; distinctly of opinion that cartilages are devoid of vascularity, i. 227; case of bony anchylosis of the right condyle of the lower jaw, i. 247; apparatus for fractured clavicle, i. 551; on the production of callus, i. 567; on the causes of congenital dislocation; i. 769: on the contents of the sac formed by the prolapsed vagina, ii. 105; on incontinence of urine in prolapse of the womb, ii. 106; on the altered form and direction of the os uteri in prolapse of that organ, ii. 106; on the elongation of the womb in prolapse, ii. 106; on the formation of calculi in the displaced bladder consequent on prolapsus uteri, ii. 106; on displacement of the rectum consecutive to prolapse, ii. 107; on excision of the prolapsed scirrhous womb, ii. 115; on the causes of club-foot, ii. 176; case of opening of the rectum under the glans penis, ii. 328; on encysted swellings, ii. 458.

Cuillvier, M., on the solution of the chloride of lime in the treatment of foul, gangrenous, or torpid ulcers, i. 616.

Cullen, Dr., on the proximate cause of inflammation, i. 27.

Cullen, Mr. **Peter**, on the treatment of hæmorrhage consecutive on the extraction of a tooth, i. 709.

Cumming's, Dr., description of cancrum oris, i. 62.

Cuming's, Mr., case of resection of the clavicle, ii. 1003.

Cunningham's, Dr., case of compound fracture of the skull, and lodgment of the breech of a pistol within the cranium, i. 395.

Cupping, ii. 867.

Curling, Mr., on the effects of the scorpion sting, i. 351: on the proximate cause of tetanus, i. 378; on hæmatocele of the spermatic cord, ii. 457.

Curvatures:—definition, ii. 148; causes, ii. 148; condition of the muscles in curvatures, ii. 149; Guérin on the condition of the muscles in curvatures, ii. 150; disease of the bones as causes of curvature, ii. 150; prognosis, ii. 150; treatment, ii. 150; subcutaneous division of the muscles, or their tendons or aponeuroses, when the muscles are contracted and changed in their tissue, ii, 151; *wry neck*, ii. 152; definition and causes, ii. 152; Stromeyer and Dieffenbach on the causes of wry neck, ii. 153: Syme's case, ii. 153; Brodie's case of wry neck alternating with insanity, ii. 153; Syme on the distorted position of the head caused by caries between the occiput and atlas, as liable to be mistaken for wry neck from muscular contraction, ii. 153; prognosis, ii. 154; treatment, ii. 154; Jörg's apparatus for keeping the head straight, ii. 154; division of the sterno-cleido-mastoideus, ii. 154; its subcutaneous section, ii. 155; mode of performing the operation, ii. 155; section of other muscles sometimes requisite, ii. 155; after-treatment, ii. 155; Stromeyer on the after-treatment, ii. 156; spasm of the sterno-cleido-mastoideus a cause of wry neck, ii. 156; Gooch's case of spasm of the platysma myoides cured by operation, ii. 156; treatment of wry neck caused by large scars, ii. 156; their entire extirpation requisite, ii. 156; wry neck from curvature of the cervical vertebræ, unaccompanied by anchylosis, ii. 157; *curvatures of the spine*, ii. 157; directions of spinal curvatures, ii. 158; Meckel, Jörg, and Choulart on the influence of spinal curvature on the transverse diameter of the pelvis, ii. 158; *inclination of the spinal column to one side*, ii. 158; high shoulder, ii. 159; South on the causes of high shoulder, ii. 159; general symptoms attending lateral inclination of the spine, ii. 159; *posterior curvature of the spine, cyphosis*, ii. 159; symptoms, ii. 160; *inclination of the spine forwards*, ii. 160; occasional causes of spinal curvature, ii. 160; Stromeyer on palsy of the serratus magnus as a cause of scoliosis or lateral curvature, ii. 161; Gunther on the condition of the muscles in snake-like scoliosis, ii. 161; Link on the situation and direction of scoliosis, ii. 161; Syme on wry neck as a cause of lateral curvature, ii. 161; diagnosis, ii. 161; Delpech on the swelling of the fibrous inter-cartilage as a cause of spinal curvature, ii. 162; symptoms and progress, ii. 162; curvature of the spine from softening of the bones, ii. 163; prognosis ii. 163; South condemns the practice of lifting by the head, ii. 164; treatment of spinal curvature, ii. 164; application of apparatus acting by pressure, ii. 164; apparatus operating by extension, ii. 165; apparatus acting by extension and pressure, ii. 165; the latter only can act efficiently, ii. 167; use of gymnastics with the extending apparatus, ii. 167; effects of gymnastics, ii. 167; treatment when the cause of the curvature is an unequal contraction of the muscles, ii. 168; Guérin on the section of the contracted muscles, ii. 169; Robert Hunter and Syme on the section of muscles in spinal curvature, ii. 169; internal treatment in curvatures dependent on great muscular weakness, ii. 170; treatment of high shoulder, ii. 170; of curvature of the spine depending on softening and thickening of the fibrous inter-cartilage, ii. 170; on rickets, ii. 171; on rheumatism, ii. 171; curvatures of the spine from contraction of one side of the chest, incurable, ii. 171; from shortening of one of the lower limbs, ii. 171; *curvatures of the limbs*, ii. 171; nature and causes, ii. 171; *curvatures of the lower limbs*, ii. 172; more frequent than those of the upper, ii. 172; *curvatures of the hip*, ii. 172; causes, ii. 172; treatment, ii. 172; Stromeyer's case in which the section of the pectineus and sartorius was practised, ii. 172; *curvatures of the knee*, ii. 172; causes, ii. 172; to be distinguished from the curvature of anchylosis, ii. 172; *in-knee*, ii. 173; characters, ii. 173; treatment, ii. 173; *curvature of the knee outwards*, ii. 173; of rare occurrence, ii. 173; *curvature of the knee forwards*, ii. 173; causes, ii. 173; treatment, ii. 173; section of the hamstring tendons, ii. 173; objections to the operation, ii. 174; performance of the operation, ii. 174; Fergusson on dislocation of the knee after the division of the hamstring tendons, requiring amputation, ii. 174; Stanley's case of contracted knees, cured by the subcutaneous section of the hamstring tendons, ii. 174; *curvatures of the feet*, ii. 174; varieties of curvature, ii. 174; *club-foot*, ii. 174; characters, ii. 175; various degrees of club-foot, ii. 175; causes, ii. 175; condition of the parts engaged in club-foot, ii. 176; Paré, Duverney, Scarpa, Brüchner, Naumberg, Wantzel, Delpech, Rudolphi, Camper, Glisson, Cruveilhier, Martin, Scoutetten, Duval, and Blasius on the causes of club-foot, ii. 176; Little on the diagnosis between club-foot and the deformity of the tarsus caused by rickets ii. 176; South's case of hysterical club-foot ii. 177; South's cases of club-foot from palsy of the muscles of the leg, ii. 179; prognosis, ii. 179; treatment, ii. 179; indications of treatment, ii. 179; South on the treatment of club-foot in early infancy, ii. 180; Scarpa's machine for club-foot, ii. 180; South on the application of Scarpa's shoe, ii. 181; subcutaneous division of the tendons, ii. 181; division of the tendo Achillis, ii. 181; Thilenius, Michaelis, Sartorius, Delpech, Stromeyer, Stoëss, Bouvier, Guérin, Scoutetten, Dieffenbach, and South on the section of the tendo Achillis, ii. 182; treatment of the foot after the division of the tendon, ii. 182; application of the extending power after the wound has healed, ii. 182; South on the application of the extending power, after the performance of the operation, and the healing of the wound, ii. 183; division of the plantar fascia, ii. 183; of the tendons of tibialis anticus and extensor proprius pollicis, ii. 184; of the tibialis posticus, flexor pollicis longus, flexor pollicis brevis, and adductor pollicis, ii. 184; South on the division of the plantar fascia, ii. 184; South on the division of the tendon of the tibialis posticus, and on the danger of wounding the posterior tibial artery during the operation, ii. 184; after treatment, ii. 184; Blasius' opinion against tenotomy in club-foot, ii. 185; *splay-foot*, ii. 185; characters, ii. 185; inconveniences of splay-foot, ii. 185; distinguished from broad-foot, ii. 185; causes, ii. 186; Liston, Froriep, Rognetta, Thune, and Stromeyer on the causes of splay-foot, ii. 186; Thune on primitive and secondary valgus, ii. 186; treatment, ii. 187; Held on the division of the peronei muscles in splay-foot, ii. 187; South on the cause of mischief in splay-foot, ii. 187; *horse-foot*, ii. 188; characters, ii. 188; causes, ii. 188; treatment, ii. 188; Jörg's apparatus, ii. 189; South on ulceration of the calf as a cause of horse-foot, ii. 189; South's case of horse-foot from palsy, ii. 189; South's apparatus for horse-foot, ii. 189; *hook-foot*, ii. 189; characters, ii. 189; treatment, ii. 190; Tyrrell's case of hook-foot, arising from an accident, ii. 190; *curvature of the upper limbs*, ii. 191; *curvatures of the shoulder*, ii. 191; of rare occurrence, ii. 191; symptoms and treatment, ii. 191; *curvatures of the elbow*, ii. 191; except when depending on anchylosis or inflammatory deposit in the soft parts about the joint, caused by contraction of the biceps and brachialis anticus, ii. 191; treatment, ii. 191; division of the tendon of the biceps, ii. 191; *curvatures of the hand*, ii. 191; causes and characters, ii. 191; *permanent bending of the hand*, ii. 192; characters, ii. 192; Lode on two kinds of curvature of the hand, ii. 192; causes and treatment, i. 192; *permanent straightening of the hand*, ii. 192; of rare occurrence, ii. 192; characters, ii. 192; *permanent bending of the fingers*, ii. 192; causes, ii. 192; diagnosis, ii. 192; curvature caused by contraction of the palmar fascia, ii. 192; characters, ii. 192; Goyraud and Sanson on the retraction of the tendons, ii. 193; signs of the curvature when caused by contraction of the flexor muscles, ii. 193: by a cicatrix, ii. 193; by palsy, or section of the extensor tendons, ii. 193; by anchylosis, ii. 193; division of the palmar fascia, ii. 193; treatment of curvature from a cicatrix, ii. 194; curvatures of bones and their treatment, ii. 194.

Custance's, Mr., case of blacking-pot in the rectum, ii. 393.

Cusack's, Mr., mode of operating in excision of the lower jaw with the condyles, ii. 990; on the non-necessity for tying the carotid artery, prior to excision of the lower jaw, ii. 993; cases of exarticulation of the lower jaw ii. 993.

Cyphosis, ii. 158.

Cystectasy, ii. 642.

Cysticercus cellulosa, ii. 703.

Dahl's, M., artery-compressor, i. 299.

Dailliez, M., on strangulation of intestine in the concavity formed by the inverted womb, ii. 118.

Dallam, Mr., on the use of raw cotton in the treatment of burns, i. 114.

Dalrymple, Mr., on the treatment of branching aneurism, ii. 275; case of ossified encysted tumor of the eyelid, ii. 699; on the nature and characters of tumors of the nose, ii. 851.

Davat's, M., operation for varicocele, ii. 297.

Davenport's, Mr., case of consecutive hæmorrhage after the extraction of a tooth, i. 709.

David's, M., case of excision of a joint, ii. 968.

Davidson's, Mr., successful operation for lacerated perineum, i. 611; case of artificial retention of the fæces for several days after the operation, i. 612.

Davie's, Mr., operation for removing the dislocated sternal end of the clavicle, i. 779; case of excision of a joint, ii. 969.

Davies, Dr., on the operation for empyema, ii. 478.

Deadrick's, Dr., case of excision of part of the side of the lower jaw without the condyle, ii. 988.

Dease, Mr., refers the principal cause of disease in injuries of the skull, not to inflammation and suppuration of the dura mater, but to injury of the pia mater and brain, i. 385; on the cases in which the cranium is laid bare, contused, or its tables simply divided, i. 386; rules for the application of the trephine, i. 387; on puncturing the dura mater, when pus is not found between it and the bone, i. 387; objection to the use of the trephine in simple fractures, i. 393; only employs the trepan when secondary symptoms of irritation and pressure require it, i. 412; case in which the temporary ligature was employed, ii. 222.

Deckers, Mr., on tapping lumbar or psoas abscess with a trocar, i. 189.

Delpech's, M., cases of malignant pustule, i. 65; commendation of cubebs in gonorrhœa, i. 174; has shewn that cubebs do not cause inflammation of the testicles, i. 175; treatment of gonorrhœa, i. 175; on the after-management of ligatures on arteries, i. 306; denies the possibility of simple dislocation of the spine, i. 534; apparatus for fractured clavicle, i. 551; on the in-locking of the broken ends of the bone in fracture of the neck of the femur, i. 564; on the rotation of the foot outwards, i. 564; on inversion of the foot, i. 565; on frictions with the ung. hydrarg. cin. in primary syphilis, i. 658; on the diseased condition of bones in syphilis not caries, but necrosis, i. 684; enterotome, and operation for artificial anus, i. 723;

on urethroplasty, i. 742; on the swelling of the fibrous inter-cartilage as a cause of spinal curvature, ii. 162; on the causes of club-foot, ii. 176; on the section of the tendo Achillis in club-foot, ii. 182; on ligature of the external iliac, ii. 261; on the ligature of the spermatic veins in varicocele, ii. 297; mode of extirpating piles, ii. 302; objections to gastrotomy or entorotomy, ii. 390; case of sarcomatous enlargement of the scrotum, ii. 711; on extirpation of the womb, ii. 826; modification of the Indian method of rhinoplasty, ii. 836; case of division of the ulnar nerve, ii. 887; case of division of the posterior tibial nerve, ii 887; mode of amputating at the hip-joint with the flap cut with a single flap, ii. 936.

Demme's, M., apparatus for ligaturing complete rectal fistulæ, i. 733.

Denan's, M., practice in wounded intestine, i. 464.

Deneux's, M., case of wound of the womb, i. 486.

Desault. M., on the treatment of in-growing of a nail, i. 199; artery-compressor, i. 299; only employs the trepan in injuries of the head when secondary symptoms of irritation and pressure require it, i. 412; on the stanching the bleeding from a wounded intercostal artery, i. 448; bandage for rupture of the tendo Achillis, i. 493; case of simple dislocation of the spine, i. 535; apparatus for fractured clavicle, i. 551; treatment of fractured olecranon, i. 561; on the in-locking of the broken ends of the bone in fracture of the neck of the femur, i. 564; on the rotation of the foot outwards, i. 564; apparatus for fracture of the neck of the femur, i. 569; on permanent extension in fracture of the femur, i. 574; on the treatment of salivary fistula, i. 713; on the treatment of fistula of the parotid duct, i. 715; on the treatment of artificial anus, i. 723; apparatus for ligaturing complete rectal fistulæ, i. 733; on the treatment of recto-urethral and recto-vesical fistula, i. 748; on the treatment of vesico-vaginal fistula by drawing off the urine and by compression, i. 752; on the primitive direction of dislocation of the humerus, i. 782; on the surgical treatment of dislocation of the thumb from the metacarpal bone, i. 794; on the spontaneous cure of umbilical rupture, ii. 82; fatal operation for the radical cure of umbilical rupture by ligature, ii. 83; case in which he performed Anel's operation for aneurism, ii. 215; mode of operating in ovarian dropsy, ii. 487; mode of treating congenital hydrocele, ii. 508; mode of amputating by the circular incision, ii. 891; mode of amputating at the shoulder-joint, ii. 957.

Deschamps', M., case of displacement of the heart, ii. 96; case in which Brasdor's operation was performed, ii. 229.

Deuber, M., on the application of sutures in vesico-vaginal fistula, i. 755.

Dewar's, Mr. H., treatment of fistulous passages, i. 93.

Diathesis purulenta, i. 45.

Dick, Professor, on the nature of the disease in hydrophobia, i. 367.

Dickin's, Mr., case of foreign body in the bronchus, in which tracheotomy was performed, and the foreign body extracted with the forceps, ii. 402.

Diday, M., on the seat of strangulation in rupture, ii. 11.

Dieffenbach, M., on the general treatment of coxalgy, i. 267; on the torsion of arteries, i. 308; torsion-forceps, i. 310; objections to torsion, i. 311; thin insect pins, and the twisted suture, i. 327; on the sutures in the operation for hare-lip, i. 598; on the removal of the edges of the cleft in staphyloraphy, i. 604; mode of uniting the cleft, i. 605; operation when the cleft is very large and complicated, i. 606; on the after-treatment, i. 607; mode of closing the fissure which sometimes remains after the operation, i. 607; on the operation for the treatment of lacerated perineum, i. 611, on the application of the sutures, i. 611; on the artificial retention of the fæces for several days after the operation, i. 612; cure of artificial anus from a lance-wound by the actual cautery, i. 725; on the treatment of callous urinary fistula, i. 740; on the suture of urethral fistula, i. 741; on the introduction of the running stitch, i. 741; on urethroplasty, i. 742; on the operation of urethroplasty in fistulas near the scrotum, i. 742; in large fistulas in the middle or fore-part of the penis, i. 742; in fistulas close behind the prepuce, i 743; in large openings immediately behind the glans, with deficient prepuce, i. 743; on cauterization as a means of cure in vesico-vaginal fistula, i. 752; mode of applying sutures in vesico-vaginal fistula, i. 754, 755; on the after-treatment, i. 756; treatment of large vesico-vaginal fistulæ by drawing the mucous membrane together, i. 758; treatment of moderately large fistula with a projecting fold of the bladder, i. 758; case of old dislocation of the humerus, to reduce which the tendons of several muscles were divided, i. 786; on the use of the actual cautery in prolapsus uteri, ii. 113; on the causes of wry-neck, ii. 153; on section of the tendo Achillis in club-foot, ii. 182; operation for considerable narrowing of the mouth, ii. 316; operation to remedy the opening of the rectum into the vagina, ii. 327; operation of chiloplasty, ii. 775;

modification of the Indian method of rhinoplasty, ii. 836; operation for defects of the wings of the nose, ii. 840; modification of the operation for sunken nose, ii. 840; operation for raising a sunken nose, ii. 843; operation for dropping in of the bridge of the nose, from the destruction of part of the septum, ii. 845; operation to remedy the turning downwards of the tip of the nose, ii. 845; operation for the subcutaneous division of the nerves of the cheek, ii. 885; case of exarticulation of metatarsal bones, with the diseased bones of the tarsus, ii. 953; mode of operating in extirpation of the superior maxillary bone, ii. 995.

Dietrich, M., on ligature of the common carotid, ii. 234; on ligature of the external carotid, ii. 237; of the lingual artery, ii. 238; of the external maxillary or facial, ii. 239; on the operation for the ligature of the subclavian on the tracheal side of the scalenus, ii. 244; on ligature of the innominata, ii. 246; of the vertebral artery, ii. 249.

Dionis' artery-compressor, i. 299; on incision of the hernial sac and the introduction of lint-tents for its radical cure, ii. 24; on amputation just above the ancle, ii. 921.

Dislocations:—definition, i. 762; various kinds of dislocations, i. 762; various degrees of distortion, i. 763; diagnosis, i. 763; South on the diagnosis of dislocations, i. 763; occasional causes, i. 763; South and Lawrence on dislocations from muscular action, i. 763; Astley Cooper's cases of dislocation from a lax condition of the ligamentous capsules of the joints, i. 764; Travers jun.'s case of dislocation into the ischiatic notch in a boy five years old, i. 764; Malgaigne on the frequency of dislocation in the different joints, i. 764; laceration of the ligaments, etc., in complete dislocations, i. 764; formation of a new joint in old dislocations, i. 764; prognosis, i. 765; reduction of the dislocated bone more or less difficult according to the circumstances of the case, i. 765; Liston's case of speedy reduction of a dislocated femur, i. 765; South on the reduction of dislocations, i. 765; treatment of dislocations, i. 765; reduction of the dislocated bone by extension and counter-extension, i. 765; South on the reduction of old dislocations, and on the necessity of caution in practising extension, i. 766; Cline jun.'s case of reduction of an old dislocation of the humerus, i. 766; obstacles which render the reduction difficult or impossible, i. 766; treatment of old dislocations, i. 766; obstacles to the reduction of old dislocations, i. 767; South, Smith, Dupuytren, and Breschet on the reduction of old dislocations, i. 767; remedies to reduce the muscular power, i. 767; after-treatment, i. 767; South on the recurrence of dislocation after reduction, from exhaustion of the muscular power, i. 767; treatment of sprains, i. 768; South on the auxiliary treatment in reducing dislocations, i. 768; compound dislocations, i. 768; treatment, i. 768; removal of the head of the bone in compound dislocation, when it cannot be reduced, i. 768; treatment of dislocation attended with fracture, i. 769; congenital dislocations, i. 769; Hippocrates, Avicenna, Paré, Palletta, Sandefort, Schreger, and Dupuytren on congenital dislocation of the hip, i. 769; Schreger, Dupuytren, Breschet, E. Stromeyer, D'Outrepont, Cruveilhier, von Ammon, and Guérin on the causes of congenital dislocations, i. 769; post-mortem appearances, i. 769; causes of congenital dislocations, i. 770; possibility of reduction, i. 770; *dislocation of the lower jaw*, i. 770; symptoms and direction, i. 770; causes, i. 771; reduction, i. 771; South on the reduction of this dislocation, i. 771; after-treatment, i. 771; *sub-luxation of the lower jaw*, i. 772; Cooper on laxity of the ligaments of the lower jaw, i. 772; *congenital dislocation of the lower jaw*, i. 772; Guérin and Smith's cases, i. 772; *dislocation of the vertebræ*, i. 772; dislocation of the first vertebra very rare, and absolutely fatal, i. 772; causes of dislocation of the first vertebra on the second, i. 773; causes and symptoms of dislocation affecting the last five cervical vertebræ, i. 773; Walther on the simultaneous dislocation of both inferior oblique processes of one of the cervical vertebræ, i. 773; Dupuytren on the confounding cervical dislocation with rheumatic affection of the neck, i. 773; reduction of the dislocation, i. 774; dislocation of the dorsal and lumbar vertebræ always accompanied with fracture, i. 774; rupture of the ligaments, i. 775; treatment, i. 775; *dislocation of the pelvic bones*, i. 775; great violence requisite to cause dislocation, and the pelvic viscera, etc., generally injured, i. 775; treatment, i. 775; case of dislocation of the hip-bone upwards, unattended by concussion of the spinal marrow, or injury of the pelvic viscera, i. 775; dislocation of the hip-bones more readily produced if the ligaments be lax and yielding, i. 775; treatment, i. 776; dislocation of the coccyx, i. 776; treatment, i. 776; *dislocation of the ribs and their cartilages*, i. 776; dislocation of the hinder end of the ribs, i. 776; Webster, Donne, Fimicane, and Hankel's cases, i. 776; causes, situation, and symptoms, i. 776; treatment, i. 777;

dislocation of the costal cartilages, i. 777; treatment, i. 777; Astley Cooper on dislocation of the costal cartilages, i. 777; *dislocation of the collar-bone*, i. 777; is more rare than fracture, i. 777; situation, i. 777; varieties, i. 777; symptoms of dislocation of the sternal end forwards, i. 777; of dislocation upwards, i. 777; of dislocation backwards, i. 778; Pellieux, Duverney, and Astley Cooper on the symptoms of dislocation backwards, i. 778; Tyrrell's case of compound dislocation backwards, i. 778; Velpeau's case of simple dislocation inwards and backwards, i. 779; mode of reduction, i. 779; Melier's apparatus for dislocation of the collar-bone forwards, i. 779; Davie's operation for removing the dislocated sternal end, i. 779; dislocation of the scapular end of the clavicle upwards, i. 780; cause and symptoms, i. 780; Tournel and Melle's cases of dislocation of the scapular end of the clavicle downwards, i. 780; mode of reduction, i. 780; South on the difficulty of keeping the dislocated scapular end reduced, i. 780; *dislocation of the upper arm*, i. 781; dislocation of the humerus more frequent than of any other bone, i. 781; varieties of dislocation, i. 781; Astley Cooper on a partial dislocation of the humerus, i. 781; Hippocrates, Duverney, Fabricius ab Aquapendente, Desault, Mursinna, Richerand, Mothe, Velpeau, and Malgaigne on the primitive direction of dislocation of the humerus, i. 782; symptoms of dislocation downwards, i. 782; of dislocation inwards, i. 782; of dislocation outwards, i. 782; of imperfect dislocation, i. 782; causes, i. 782; injury to the soft parts, i. 783; dislocation of the humerus occasionally attended with fracture of the neck of the bone, i. 783; reduction of the dislocation, i. 783; points to be attended to in effecting reduction, i. 784; Rust's mode of reducing the dislocation, i. 784; after-treatment, i. 784; obstacles to reduction, i. 784; reduction of the dislocation by means of the heel in the axilla, i. 785; Bertrandi and Sauter's plans of reduction, i. 785; reduction of the dislocation by means of the knee in the axilla, i. 785; use of the pulleys, i. 785; reduction of old dislocations, i. 786; Weinhold's case, in which he divided the tendon of the pectoralis major, i. 786; Gibson's case, in which the axillary artery was ruptured, i. 786; Dieffenbach's case, in which he divided the tendons of several muscles, i. 786; *congenital dislocation of the humerus*, i. 786; not of very rare occurrence, i. 786; two varieties of this dislocation, i. 786; symptoms of the congenital subcoracoid dislocation, i. 786; examination of a case of this dislocation after death, i. 787; Smith on the post-mortem appearances in congenital subacromial dislocation, i. 787; Smith on the resemblance between the congenital subcoracoid dislocation, and the partial dislocation, and that caused by rheumatic affection of the shoulder-joint, and by unusual atrophy of the arm, i. 788; evidence in favour of these dislocations being congenital, i. 788; Guillard's case of reduction of a congenital dislocation after the lapse of sixteen years, i. 788; *dislocations of the fore-arm*, i. 788; *dislocations at the elbow-joint*, i. 788; complete dislocations of the elbow rare, i. 788; dislocation backwards, i. 788; dislocation of the ulna alone backwards, i. 789; lateral dislocation, i. 789; causes of dislocation of the fore-arm backwards, i. 789; consequences of these dislocations, i. 789; they soon become irreducible, i. 789; complications of dislocation backwards, i. 790; Astley Cooper, Bransby Cooper, Malgaigne, and Lisfranc's cases of reduction of old dislocations of the elbow, i. 790; reduction of the dislocation, i. 790; Astley Cooper's mode of proceeding, i. 790; treatment to be adopted when the radius is also displaced, and in compound dislocation, i. 790; reduction of the lateral dislocation, i. 790; treatment of old dislocations, i. 791; treatment of dislocation forwards, i. 790; dislocation of the radius backwards, i. 791; dislocation of the upper end of the radius forwards, its causes and symptoms, i. 791; Boyer, Astley Cooper, Rouyer, Villaumé, Gerdy, and B. Cooper on dislocation of the upper end of the radius forwards, i. 791; Bulley and Vignolo on simultaneous dislocation of the radius forwards and of the ulna backwards, i. 791; Adams' case of longitudinal dislocation of the radius, i. 791; reduction of this dislocation, i. 792; Astley Cooper on the difficulty attending the reduction of this dislocation, i. 792; *dislocations of the wrist*, i. 792; three kinds of dislocation, i. 792; dislocation of the hand from the bones of the fore-arm, i. 792: varieties of this dislocation, i. 792: Dupuytren doubts the occurrence of dislocation of the wrist, the presumed cases of which he regards as fracture of the lower end of the radius, i. 792; Voillemier's case of dislocation of the wrist, i. 792; Voillemier on the diagnostic signs of dislocation of the wrist, and fracture of the lower end of the radius, i. 792; causes, i. 793; mode of reduction, and after-treatment, i. 793; dislocation of the radius alone, i. 793; of the ulna alone, i. 793; *dislocation of single bones of the hand*, i. 793; dislocation of the great bone, and its treatment, i. 793; Gras' case of dislocation of the pisiform bone, i. 794; partial dislocation of the great and unciform bones, i. 794; dislocation of the metacarpal bone of the thumb, i. 794; reduction and after-treatment, i. 794; dislocation of the phalanges of the fingers, i. 794; mode of reduction, i. 794; Roser and Fincke on dislocation of the thumb from the metacarpal bone, i. 794; Desault, Dupuytren, Evans, and Vidal on the surgical treatment of this dislocation, i. 794; Astley Cooper, Lisfranc, Dupuytren, Hey, Vidal, Malgaigne, Pailloux, Lawrie, Blechy, and Roser on the cause of the difficulty experienced in reducing this dislocation, i. 794; Hey, Charles Bell, Fincke, Liston, Reinhardt, and Roser on the mode of reducing this dislocation, i. 795; *dislocation of the femur*, i. 795; divisions, i. 795; Astley Cooper on the relative frequency of dislocations of the femur, i. 795; South on repeated dislocations of the femur in the same person, i. 795; symptoms of dislocation upwards and backwards, i. 796; of dislocation inwards and downwards, i. 796; Ollivier on dislocation of the femur directly downwards, i. 796; dislocation backwards and downwards into the ischiatic notch, i. 796; regarded by Boyer as secondary, i. 797; dislocation upwards and inwards, i. 797; prognosis, i 797; the reduction of these dislocations, i. 797; mode of reduction, i. 798; Wattmann, Kluge, and Rust's methods of replacement, i. 798, 800; Colombat's mode of reduction, i. 800; reduction of these dislocations by pulleys, i. 800; Astley Cooper on the reduction of the dislocation downwards, i. 801; Morgan and Cock on the reduction of the dislocated femur by placing the foot between the thighs, extension and rotation being made at the same time, i. 801; completion of the reduction, and subsequent treatment, i. 801; congenital dislocation, i. 802; described by Hippocrates, Palletta, and Dupuytren, i. 802; symptoms, i. 802; Dupuytren and Palletta on the post-mortem appearances, i. 803; Dupuytren on the local treatment of this dislocation, i. 803; Duval, Jalade Lafond, Humbert, Pravaz, and Guérin on the reduction of this dislocation, i. 803; Pravaz and Guérin's cases of successful reduction, i. 804: Heine's apparatus, i. 804; Guérin's mode of proceeding in effecting the reduction, i. 804; *dislocation of the knee-cap*, i. 804; varieties, i. 804; diagnosis, i. 804; Coze and Wolf on twisting round of the patella, i. 805; causes, i. 805; mode of reduction, i. 805; congenital dislocation of the patella, i. 805; Palletta's case, i. 805; *dislocation of the knee-joint*, i. 805; of rare occurrence, i. 805; is generally incomplete, i. 805; mode of reduction, i. 806; Astley Cooper on dislocation of the semi-lunar cartilages, i. 806; Wutzer and Kleberg on congenital dislocation of the knee, i. 806; *dislocation of the splint-bone (fibula)*, i. 806; direction of the dislocation, i. 806; mode of reduction, i. 806; treatment, i. 806; *dislocation of the ancle-joint*, i. 807; direction of the dislocations, i. 807; symptoms of the dislocation inwards, i. 807; of the dislocation outwards, i. 807; dislocation of the foot forwards, i. 807; dislocation backwards, i. 807; consequences of these dislocations, i. 808; mode of reduction, i. 808; Earle's case of dislocation of the ancle inwards, with laceration of the internal lateral ligament, i. 809; compound dislocations of the ancle, i. 809; South on the English practice in such cases, i. 809; *dislocation of the bones of the tarsus*, i. 809: of very rare occurrence, and only from great violence, i. 809; dislocation of the astragalus, i. 809; direction, causes, and symptoms, i. 809; twisting round of the astragalus on its axis, i. 810; Rognetta on dislocation of the astragalus inwards, i. 810; James, Guthrie, and Stanley's cases of dislocation outwards, i. 810; dislocation forwards, i. 810; dislocation inwards, i. 810; dislocation outwards, i. 810; Dupuytren, Boyer, and South on reduction of the dislocation, i. 811; mode of reduction, i. 811; treatment to be adopted, if the reduction be impossible, i. 811; removal of the astragalus, i. 812; removal of the bone necessary when it is twisted on its axis, i. 812; the operation should be performed early, i. 812; dislocation of the os calcis, i. 812; South and Hancock's cases, i. 812, 813; dislocation of the navicular and cuboid bones, i. 813; always the result of great violence, i. 813; mode of reduction, i. 813; dislocation of the cuboid, i. 813; treatment, i. 813; dislocation of the great cuneiform bone, i. 813; mode of reduction, i. 813; Astley Cooper's cases, i. 813; dislocation of the metatarsal bones, i. 813; Dupuytren's case, i. 814; mode of reduction, i. 814; Green's case of dislocation of the two outer metatarsal bones, i. 814; dislocation of the toes, i. 814; mode of reduction, i. 814; Astley Cooper's case, i. 814.

Dixon's, Mr., case of resection of a costal cartilage, ii. 1006.

Dobson's, Sir R., treatment of erysipelas by punctures with a lancet, i. 107, 108.

Dodard, M., mortification from spurred rye first noticed by, i. 61.

Doellinger, M., on the formation of new vessels, i. 292.

Dohlhoff's, M., case of encysted abscess of the abdomen, ii. 493.

Donige's, M., plan of bringing the edges of the cleft together in staphyloraphy, i. 604; instrument for drawing the knots, i. 605.

Donné, M., on the microscopic characters of pus, i. 35; case of dislocation of the ribs, i. 776.

Dornbluth's, M., artificial leg, ii. 846.

Douglas, Dr. **James**, on Cheselden's operation for stone, ii. 586; on the dissection of the parts concerned in this operation, ii. 587.

Douglas, Mr. **John**, originally proposed the operation of lithectasy, ii. 642.

Dran, Le, M., on superficial whitlow only a disease of the skin, i. 192; considers paronychia tendinosa to be caused by erysipelatous inflammation, i. 193; asserts that Richter's dry whitlow depends on disease of the bone, i. 194; on immediate amputation in gunshot wounds, i. 345; on the reduction *en masse*, ii. 16; on ligature of the hernial sac for its radical cure, ii. 24; mode of operating in ovarian dropsy, ii. 487; mode of amputating at the shoulder joint, ii. 956.

Dubled, M., on extirpation of the womb, ii. 827; operation for excision of the wrist-joint, ii. 977.

Dubourg, M., on the treatment of spina bifida by closure of the sac, ii. 469.

Ducamp's, M., mode of cauterizing the urethra for stricture, ii. 368; mode of dilating the urethra after cauterization, ii. 369; caution respecting the use of caustic, ii. 370.

Ducros, M., jun., on dislocation forwards on the share-bone in hip disease, i. 259.

Duges', M., obturator for vesico-vaginal fistula, i. 751; on anteversion of the womb, ii. 146; case of spontaneous reduction of anteversion, ii. 147.

Duhamel, M., on mortification from spurred rye, i. 61.

Duncan's, Dr., condemnation of the treatment of erysipelas by moderate compression, i. 108.

Duparcque, M., on the fibrous or cartilaginous resistance of the tissue of the womb, i. 482; case of accumulation of blood in the womb, i. 483; on rupture of the womb during pregnancy, i. 483; on the danger and immediate treatment of rupture of the womb, i. 483; on partial rupture of the uterus from a collection of fluid in its parietes, i. 484; cases of abscess of the womb, i. 484; on punctures or narrow lacerations of the womb, i. 486; on the treatment of lacerations of the perineum, i. 609; on the scarring of the edges of the torn perineum, i. 609; case of recto-vaginal fistula cured spontaneously, i. 760; on the indications for the treatment of recto-vaginal fistula, i. 760.

Duphœnix, M., on the use of a canula for maintaining the patency of the artificial duct in the operation for salivary fistula, i. 714.

Dupuy's, M., experiments on the division of both pneumogastric nerves, i. 432.

Dupuytren, M., on arteritis, a cause of dry gangrene, i. 59, 60, 75; on the treatment of senile gangrene in plethoric subjects by the antiphlogistic plan of treatment, i. 96; on incisions in pseudo-erysipelas, i. 108; treatment of pseudo-erysipelas and common erysipelas by blisters, i. 108; sub-division of burns, i. 110; on incisions in carbuncle, i. 138; on lumbar abscess generally connected with carious vertebræ, i. 186; on the changes that sometimes take place in the abscess, i. 188; leaves lumbar abscess to nature, i. 190; recommends cauterization, or weak injections of nitrate of silver, or nitric acid, in the treatment of the sinuous cavities resulting from lumbar abscesses, i. 191; on ingrowing of the nail, i. 198; states it to have been mistaken for gout, i. 199; operation for dividing and removing the diseased nail in ingrowing, i 200; on onychia maligna, i. 202; on the removal of the nail with its secreting surface in treating onychia, i. 203; on the introduction of a piece of bougie into an ossified artery after amputation, i. 304; on the effects of torsion, i. 311; objections to torsion, i. 311; on the effects of gun-shot, i. 336; case of a person killed by a gun loaded with powder only, i. 336; on the splitting of the ball by the sharp edge of the bone, i. 339; on secondary hæmorrhage, i. 341; on amputation in tetanus, i. 380: case of abscess of the brain successfully opened, i. 399; distinguishes between commotion and contusion of the brain, i. 410; objects to the return of the protruded omentum into the cavity of the abdomen in penetrating wounds of the abdominal parietes, i. 461; modification of Lembert's plan of treating wounded intestine, i. 469; experiments on the extravasation of bile and urine, i. 479: on the two periods in the formation of bone, i. 499; on the production of callus, i. 501; treatment of fractured sternum, i. 546; treatment of fractured clavicle, i. 552; treatment of fracture of the humerus, i. 556; on fracture of the lower end of the radius, i. 558; on the treatment of fracture of the radius or ulna near the wrist, i. 559; on inversion of the foot in fracture of the neck of the femur, i. 565; on the treatment of fracture of the neck of the femur, i. 570; on the advantages of the double-inclined position, i. 571; on the duration of the treatment in these cases, i. 571; on the sawing off the ends of the broken bone in false joint, i. 591; on the operation for the treatment of lacerated perineum, i. 611; on the appearances presented on post-mortem examination some time after the cure of an artificial anus, i. 720: application of the enterotome for the cure of artificial anus, i. 722; Seiler's modification of it, i. 723; on the symptoms of anal fissure, i. 735; on the three varieties of anal fissures, i. 735; on the treatment, i. 736; treatment of recto-urethral and recto-vesical fistula, i. 748; on cauterization as a means of cure in vesico-vaginal fistula, i. 752; on the reduction of old dislocations, i. 767; on congenital dislocations of the hip, i. 769; on the causes of congenital dislocations, i. 769; on the confounding cervical dislocation with rheumatic affection of the neck, i. 773; doubts the occurrence of dislocation of the wrist, the presumed cases of which he regards as fracture of the lower end of the radius, i. 792; on the surgical treatment of dislocation of the thumb from the metacarpal bone, i. 794; on the cause of the difficulty experienced in reducing this dislocation, i. 794; on congenital dislocation of the femur, i. 802; on the post-mortem appearances, i. 803; on the local treatment, i. 803; on reduction of dislocation of the astragalus, i. 811; case of dislocation of the metatarsal bones, i. 814; on the reduction *en masse*, ii. 16; modification of the operation for femoral rupture, ii. 73; operation for mesenteric strangulation, ii. 94; objections to scarifications or leeches in treating prolapse of the rectum, ii. 133; operation for long-standing prolapse of the rectum, ii. 134; objections to the actual cautery in irreducible prolapse, ii. 136; case of aneurism mistaken for abscess, ii. 201; on the section of the scalenus anticus in ligature of the subclavian, ii. 242; on the treatment of branching aneurism, ii. 275; plan to prevent re-union after the operation for united fingers or toes, ii. 309; case of a foreign body remaining a long time in the windpipe, ii. 396; mode of operating for ranula, ii. 407; on the operative treatment of encysted swellings, ii. 460; on cutting away the tunica vaginalis, ii. 506; bilateral section for stone, ii. 596; operation for stone, ii. 616; on encysted cellular fibrous tumor of the maxillary antrum and its treatment, ii. 746; operation for the excision of the cancerous neck of the womb, ii. 821; mode of amputation by the circular incision, ii. 891; practice of leaving the wound of the stump exposed for several hours after the operation, ii. 895; mode of dressing stumps, ii. 904; mode of amputating at the hip-joint with two flaps, ii. 938; at the shoulder-joint, ii. 956, 957, 959; mode of operating in exarticulation of the fore-arm at the elbow, ii. 962; on exarticulation of the middle and ring fingers, ii. 966; mode of operating in excision of the elbow-joint, ii. 975; recommends the non-division of the ulnar nerve in that operation, ii. 975; case of excision of the lower jaw, ii. 987; cases of extirpation of the upper jaw doubted by Gensoul, ii. 994.

Dura mater, fungus of, ii. 683.

Dussausoy, M., recommends emetics in hospital gangrene, i, 97; on the rotation of the foot outwards in fracture of the neck of the femur, i. 564.

Duval's, M., local steam-bathing apparatus, i. 266; on the reduction of congenital dislocation of the femur, i. 803; on the causes of club foot, ii. 176.

Duverney, M., on the lengthening of the limb in hip disease, i. 257; treatment of fractured olecranon, i. 560; apparatus for fracture of the neck of the femur, i. 569; on the symptoms of dislocation of the sternal end of the clavicle backwards, i. 778; on the primitive direction of dislocation of the humerus, i. 782; on the causes of club foot, ii. 176.

Dyckman's, M., assertion that a child may be infected by the milk of a diseased nurse, i. 673.

Dzondi's, M., apparatus for fracture of the neck of the femur, i. 570; treatment of syphilis, i. 668; urinary receptacles for vesico-vaginal fistula, i. 751; plan of inhealing a plug of skin for the radical cure of rupture, ii. 24; mode of operating in ovarian dropsy, ii. 487; on the ligature of the carotid, prior to excision of the lower jaw with the condyles, ii. 990.

Earle's, Mr., comments on Dr. John Thompson's experiments with respect to the state of the vessels in inflammation, i. 28; on cold moist applications in the treatment of burns, i. 113; on the removal of the clothes after burns and scalds, i. 117; on the contraction of the cicatrix in cases of burns, i. 120; on the effects of this contraction, i. 121; operation for the removal of the entire scar, i. 121; case in which this operation was performed, i. 122; on dislocation into the ischiatic notch in hip disease, i. 258; apparatus for fractured clavicle, i. 551; treatment of fractured olecranon, i. 561; description of apparatus, i. 561; on some of the signs of fracture of the neck of the femur, i. 564; opposed to Astley Cooper's views on bony union in these fractures, i. 566; fracture-bed, i. 571, 574; on urethroplasty, i. 742; obturator for vesico-vaginal fistula, i. 751; case of dislocation of the ancle inwards, with laceration of the internal lateral ligament, i. 809; case of hydrocephalocele, ii. 98; case of hydrocephalocele treated by puncture, ii. 102; case of secondary hæmorrhage after lithotomy, ii. 604; case of chimney-sweeper's cancer in the wrist, ii. 816; on the extension of the disease to the neighbouring parts, ii. 816; on the age at which the disease generally occurs, ii. 816; case of division of the ulnar nerve, ii. 887.

Ebel's, M., preparation of the parts for the operation of staphyloraphy, i. 603; on the removal of the edges of the cleft, i. 604; plan for bringing the edges of the cleft together, i, 604; instrument for drawing the knots, i. 605.

Eberl's M., straps for fractured clavicle, i. 551.

Ebers, M., on the hydriodate of potash in syphilis, i. 669.

Eble, M., on the existence of the acarus scabiei, i. 636; observations on the acarus, i. 636.

Echinoccus hominis, ii. 704.

Eckoldt's, M., method of performing œsophagotomy, ii. 385.

Eckstrom's, M., operation for cutting into the urethra in the perineum, ii. 428.

Eczema rubrum, or mercuriale, i. 678.

Edmonston's, Mr., plan of treatment in ruptured tendo Achillis, i. 494.

Ehrlich's, M., compressor, i. 298.

Ehrmann, M., on the suture in vesico-vaginal fistula, i. 755.

Eichheimer's, M., apparatus for fractured clavicle, i. 551.

Ekl's, M., opinion on the lymph-swelling, i. 48; on some of the signs of fracture of the neck of the femur, i. 564; on the inlocking of the broken ends of the bone, i. 564; on the solution of the chloride of lime in the treatment of foul, gangrenous, or torpid ulcers, i. 615.

Elbow, dislocations of, i. 788; curvature of, ii. 191; exarticulation of the fore-arm at, ii. 961; excision of the, ii. 975.

Elderton's, Mr., lithotritic instruments, ii. 558.

Elliotson's, Dr., case of gangrene of the leg after the use of ergot, the arteries of the limb being also ossified, i. 61; on glanders in the human subject, i. 64; on the period of incubation of hydrophobia, i. 367; on the symptoms of hydrophobia, i. 368; on the diagnosis between true and spurious hydrophobia, and inflammation of the pharynx, i. 369; on a general morbid irritability in hydrophobia, i. 369; on the duration of the disease, i. 370; on abortive hydrophobia, i. 370; on the post-mortem appearances, i. 371; case of prolapse of the womb in a virgin, ii. 107.

Elliott's, Mr., case in which he performed lithectasy, ii. 643.

Else, Mr., denies the existence of the so-called scirrhus of the tonsils, i 143; objection to excision of the tonsils, especially in children, on account of the hæmorrhage, i. 145; prefers Cheselden's operation, i. 145; on the use of sutures in wounded intestine, i. 466.

Elster, M., on the effects of torsion, i. 311.

Emmert, M., on the phenomena of inflammation under the microscope, i. 30; experiments on the injection of bile into the cavity of the peritoneum, i. 479.

Emery, M., on the contagion of itch, dependent on the itch-mite, i. 636.

Emphysema, i. 451.

Empyema, ii. 469.

Enterotomy, ii. 391.

Epididymitis. *See* Inflammation of the Testicle.

Epinychia, or ulceration with great thickening at the ends of the fingers, i. 194; Abernethy on the cure of epinychia, i. 198.

Epulis, i. 701.

Erethismus mercurialis, i. 677.

Erysipelas;—nature of the disease, i. 99; Rust's division into true and false erysipelas, i. 99; Hunter's opinion that most inflammations which are called erysipelatous are not such, i. 99; South on the different applications of the terms erysipelas and erythema, i. 99, 100; symptoms, progress, terminations, and causes of true erysipelas, i. 99; vesicular erysipelas, i. 100; the true erysipelas of Chelius the erythema of English practitioners, i. 100; Willan's description of erythema, i. 100; Bateman's distinction between erythema, and erysipelas, i. 100; Rayer's description of erythema, i. 100; the vesicular erysipelas of Chelius the acute erysipelas of Willan and Bateman, i. 100; the symptoms and progress of the disease, according to those authors, i. 100; causes of spurious or pseudo-erysipelas, i. 101; pseudo-erysipelas divided into erythema idiopathicum and erythema symptomaticum or consensuale, i. 101; causes of erythema idiopathicum, i. 101; South on intertrigo a very frequent form of erythema idiopathicum, and on its causes, i. 101; causes of erythema symptomaticum or consensuale, i. 101; Hunter's description of erythema symptomaticum, i. 101; erythema symptomaticum the erratic erysipelas of Willan and Bateman, i. 102; erysipelas from scalp wounds the œdematous erysipelas of Willan and Bateman, i. 102; erythema symptomaticum a metastatic deposit in the cellular tissue, periosteum and glands in gastric, rheumatic, arthritic and puerperal diseases, i. 102;

symptoms, progress, and terminations of the disease, i. 102; South's opinion that this form of erysipelas symptomaticum is the inflammation of the cellular tissue, commonly confounded with erysipelas and erythema, but decidedly different from either, although both occasionally run into it, i. 103; Hunter's description of the disease, under the name of erysipelatous inflammation, i. 103; South's account of the disease, i. 103; South's case of degeneration of the cellular tissue of the forehead and face, consequent on repeated attacks of this disease, i. 104; Gulliver's description of thickening and induration, and of induration and rigidity without thickening of the cellular tissue of the feet and ancles, as occurring in soldiers, i. 104; distinctive characters of symptomatic and idiopathic pseudo-erysipelas, i. 105; etiology of pseudo-erysipelas, i. 105; treatment of simple erysipelas, i. 106; the antiphlogistic plan of treatment, i. 106; Dr. Williams' stimulant plan of treatment, i. 106; South on the combination of both the antiphlogistic and the stimulant plans, i.106; the local treatment of erysipelas, i. 106; Rust on the application of moist warmth in vesicular erysipelas and its varieties, i. 106; treatment of erysipelas when terminating in ulceration or gangrene. i. 107; South on the local treatment of erysipelas, i. 107; Dobson's plan of relieving the hide-bound sensation by punctures with a lancet, i. 107; treatment of idiopathic erysipelas, i. 107; leeches never to be applied, but punctures made with a lancet, if necessary, i. 107; treatment of erythema consensuale, i. 107; Rust's stimulant and tonic treatment condemned by Chelius, i. 107; South on the treatment of erysipelas consensuale by incisions varying from an inch and a half to three inches in length, i. 108; Rust, Dupuytren and Lawrence of opinion that incisions should be made only in pseudo-erysipelas, and of the suitable length and depth, i. 108; Hutchinson, that they should be made early, and in considerable numbers, i. 108; Dobson employs numerous punctures with a lancet in all kinds of erysipelas, and on all parts of the body, i. 108; Dupuytren's treatment of pseudo-erysipelas by blisters, i. 108; in some cases satisfactory, but the remedy doubtful, i. 108; his opinion that the suppuration produced by blisters on the inflamed part is the best mode of effecting resolution in common erysipelas, i. 108; the extension of erysipelas arrested by some surgeons by a blister at the margin of the disease, i. 108; this plan of treatment rejected by others, i. 108; Bretonneau and Velpeau's treatment by moderate compression, i. 108; condemned by Lawrence and Duncan, i. 108; South on the application of nitrate of silver as a means of arresting the progress of the disease, i. 108; treatment of erysipelas consequent on wounds must be guided by a proper observation of its various causes, i. 109.

ERYTHEMA of English practitioners, the erysipelas of Chelius, i.100; Willan's description of, i. 100; Bateman's distinction between, and erysipelas, i. 100; Rayer's description of, i. 100; erythema idiopathicum, i. 101; erythema symptomaticum, or con sensuale, i. 101; Hunter's description of, i. 101; erythema symptomaticum the erratic erysipelas of Willan and Bateman, i. 102; erythema symptomaticum, a metastatic deposit in the cellular tissue, periosteum, and glands, in gastric, rheumatic, arthritic, and puerperal diseases, i. 102; South's opinion that this is the inflammation of the cellular tissue, commonly confounded with erysipelas and erythema, i. 103; Hunter's description of this form of the disease, i. 103; treatment of, i. 107; South on the treatment of, by incisions, i. 108.

ETHER, inhalation of, ii. 1007; Morton and Bigelow's application of, as a safeguard against pain in tooth-drawing, ii. 1007; employed by Warren, Hayward, Bigelow, Robinson, and Liston in more important surgical operations, ii. 1007; South, Bigelow, Morris, and Cotton's cases of injurious effects produced by the inhalation of ether, ii. 1008; South on the impropriety of inhaling the ether, prior to the operation for cataract, ii. 1009.

EVANS, Mr., on the surgical treatment of dislocation of the thumb from the metacarpal bone, i. 794.

EVANSON'S, Dr., description of noma, i. 62; on the suppuration of mumps, i. 149; on the communication of syphilis to the infant in the womb, i. 673; on the symptoms of syphilis in infants, i. 673; on the treatment of syphilis in infants, i. 674.

EVERS', M., apparatus for divided and ruptured tendons of the hand and fingers, i. 330; bandages for fractured clavicle, i. 551; objected to, i. 551; apparatus for fracture of the patella, i. 579.

EXUDATION;—period of its occurrence, and its results, adhesion and edema, i. 32; the term synonymous with effusion, i. 32; Dr. J. H. Bennett on the process of effusion, i. 32; Travers on the effusion of serum, i. 33; Wharton Jones on exudation, i. 33; Hunter on the cause of the extravasation of serum, i. 33; Gerber on the varieties of exudation after inflammation, i. 33; Gerber on the microscopical resem-

blance between the lymph-corpuscles and the exudation corpuscles, i. 34; this resemblance denied by Gulliver, i. 34; Valentin on the exudation-corpuscles, i. 34; treatment after exudation has taken place, i. 87.
EXOSTOSIS, ii. 673.

FABRICIUS AB AQUAPENDENTE on tearing out the tonsils, i. 145; on the primitive direction of dislocation of the humerus, i. 782; on ligature of the hernial sac for its radical cure, ii. 24.
FACE, WOUNDS OF THE, i. 427; important in wounds of the face to prevent scars, i. 427; use of sutures, i. 427; South on the twisted suture or thin pins in such wounds, i. 427; wounds of the region of the eye-brow, i. 427; cause of amaurosis in wounds of the eye-brow, i. 427; Thomson on amaurosis and inflammation of the eye, caused by the passage of a ball through or near the organ, i. 428; Fardeau's case of bayonet-wound entering the temple, and passing across through the opposite maxillary sinus, i. 428; De Limbourg's case of wound of the head with a ramrod, i. 429; Hennen on gun-shot wounds in the neighbourhood of, or penetrating the orbit, i. 429; slight longitudinal and transverse wounds of the eyelids, i. 429; wounds of the ear, i. 430; South on wounds of the gristly passage of the ear, i. 430; wounds of the nose, i. 430; bandages for the nose, i. 430; wounds of the cheek, i. 430; wounds of the tongue, i. 430; deep and transverse wounds require sutures, i. 430; Lawrence on bleeding from the tongue from bites made during a fit, i. 431.
Facial artery, ligature of, ii. 239.
FALCONER, Mr., on the lengthening of the limb in hip-disease, i. 257.
FARADAY, Mr., on the presence of globules in the serum, i. 43.
FARDEAU'S, M., case of bayonet-wound entering the temple, and passing across through the opposite maxillary sinus, i. 428.
FATIO, M., on the use of the suture in vesico-vaginal fistula, i. 753.
FAULQUIER'S, M., artery-compressor, i. 299.
FAURE, M., on the propriety of delaying amputation in gun-shot wounds, i. 345.
FAYE, M., on the operation for the ingrowing of the nail, i. 200.
FAYE'S, M. LA, apparatus for fracture of the neck of the femur, i. 569; on the reduction *en masse*, ii. 16.
FEATHERSTONE'S, Mr., case of fatal bayonet-wound of the heart, i. 455.
Feet, curvature of, ii. 174.
FEILER'S, M., treatment of fractured olecranon, i. 561; description of his apparatus, i. 561.
Femoral rupture, ii. 66.
——— artery, ligature of, ii. 261.
Femoral aneurism, ii. 258.
Femur, fractures of, i. 563; dislocation of, i. 795.
FERNE'S, M., case of accidental torsion, i. 311.
FERGUSON'S, Mr., case of protruded spleen, i. 480; on the treatment of buboes, i. 659.
FERGUSSON'S, Mr., new mode of staphyloraphy, i. 605; on dislocation of the knee after the division of the hamstring tendons, requiring amputation, ii. 174; case of opening of the rectum into the bladder, ii. 328; case in which he performed the operation of lithectasy, ii. 645; operation for raising a sunken nose, ii. 844; on the relative value of the flap and circular operations for amputation, ii. 903; on amputation through the calf of the leg, and at the shoulder-joint, ii. 903; prefers Liston's flap operation for amputation of the thigh, ii. 909; reason why the hind flap should be longer than the front, ii. 909; recommendation to excise a considerable portion of the sciatic nerve in amputation with a single flap from behind, ii. 909; mode of amputating through the leg with two flaps, ii. 920; case of excision of the head of the femur, ii. 979; mode of operating in resection of the upper jaw, ii. 999; case of resection of the scapula and clavicle together, ii. 1005; mode of operating, ii. 1005.
FERRAND'S, Mr., case of aneurism mistaken for abscess, ii. 202.
FERRIER, Dr., on an epidemic vaginal catarrh, i. 161.
FEST'S, M., apparatus for fracture of the patella, i. 579.
Fibula, fracture of, i. 581; dislocation of, i. 806; resection of, ii. 1007.
FICKER, M., on the lengthening of the limb in hip disease, i. 257; case of reduction of the consecutive dislocation, i. 268; advises the opening of abscesses at the hip with caustic, i. 269.
FILKIN'S, Mr., case of excision of a joint, ii. 968.
FINCKE, M, on dislocation of the thumb from the metacarpal bone, i. 794; on the mode of reducing this dislocation, i. 795.
Fingers, permanent bending of, ii. 192; supernumerary, ii. 850; amputation of, ii. 930; exarticulation of, ii. 966.
FINUCANE'S, M., case of dislocation of the ribs, i. 776.
FISCHER, M., on the chemical composition of pus, i. 35; on the distinguishing tests for pus and mucus, i. 44; on the application of smear, black, or green soap, i. 638.
FISHER, Mr., on the origin of spina bifida, ii. 466.
Fissures, anal, i. 734.
FISTULÆ, i. 710; definition, i. 710; John Hunter on the inadequacy of the term fistula, i. 710; causes, i. 710; Hunter on

the causes of fistula, i. 710; prognosis, i. 710; indications for the cure of fistula, i. 711; John Hunter on the cure of fistulæ, i. 711; *salivary fistula*, i. 712; signs i. 712; causes, i. 712; treatment, i. 712; treatment of fistula of Steno's duct, i. 712; restoration of the natural salivary duct, i. 712; modes of treatment proposed for that purpose, i. 712; Desault, Richter, Schreger, and Viborg on the treatment of salivary fistula, i. 713; production of an artificial duct, i. 713; mode of operating, i. 713; De Roy on the making an artificial opening in the cheek, i. 713; Perry on the passing a leaden thread into Steno's duct after the cheek has been penetrated, i. 713; completion of the operation, i. 713; Duphœnix and Atti on the use of a canula for maintaining the patency of the artificial duct, i. 714; Croserio's modification of the operation, i. 714; treatment of the fistula, i. 714; Bonafont, Desault, Béclard, and South on the treatment of fistula of the parotid duct, i. 714, 715; subsequent treatment, i. 715; fluctuating tumour of Steno's duct, i. 715; stony concretion in the salivary duct, i. 715; Syme, Astley Cooper, and Lawrence on salivary calculi, i. 715; South on the specimens of salivary calculi in the College museum, i. 715; *biliary fistula*, i. 716; causes and symptoms, i. 716; South on biliary fistulæ, i. 716; treatment, i. 717; *fæcular fistula*, i. 717; definition, i. 717; signs, i. 718; effects of fæcular fistula and of artificial anus on the system, i. 718; Begin's case of closing and wasting of the portion of intestine below the artificial anus, i. 718; Astley Cooper's case of artificial anus in the jejunum terminating fatally, i. 718; prolapse of the intestine at the artificial anus, i. 718; symptoms and results, i. 718; causes of fæcular fistula and artificial anus, i. 719; cure of artificial anus by nature and by operation, i. 719; the process adopted in the cure by nature, i. 719; Lallemand, Dupuytren, Scarpa, and Lawrence on the appearances presented on post-mortem examination, some time after the cure of artificial anus, i. 720, 721; treatment of fæcular fistula or artificial anus, i. 721; South's case of artificial anus at the navel, i. 722; King on artificial anus at the umbilicus, connected with the diverticulum ilei, i. 722; South's case of flow of colourless fluid from the navel, i. 722; Lawrence on Dupuytren's operation for artificial anus, i. 722; application of Dupuytren's enterotome for the cure of artificial anus, i. 722; Seiler's modification of Dupuytren's enterotome, i. 723; Liordat's emporte-pièce, i. 723; Reybard's modification of the operation, i. 723; Delpech's enterotome, i. 723; Desault and Schmalkalder on the treatment of artificial anus, i. 723; Physick's operation for artificial anus, i. 723; closure of the fistulous opening, i. 724; Dieffenbach's cure of artificial anus from a lance-wound by the actual cautery, i. 725; treatment of artificial anus connected with the cœcum, i. 725; Velpeau's plan of treatment, i. 725; *rectal fistula*, i. 726; definition and sub-divisions, i. 726; causes and symptoms, i. 726; abscesses about the anus, i. 726; Sabatier, Larrey, and Ribes on the internal opening of rectal fistula, i. 726; Astley Cooper's case of fistula in ano, i. 727; examination of rectal fistulæ, i. 727; cure of the rectal fistula with an internal opening, only to be effected by division of the sphincter, and of the partition between the fistulous passage and the gut, i. 727; contra-indications to the operation for rectal fistula, i. 728; Brodie and Astley Cooper on the impropriety of operating for fistula in phthisical cases, i. 728; treatment of abscesses in the neighbourhood of the rectum, i. 728; Brodie on the treatment of large abscesses high up by the side of the rectum, i. 729; usual modes of operating in rectal fistula, i. 729; the operation by cutting, i. 729; South on the operation for rectal fistula, i. 730; operation for an internal blind fistula, i. 730; dressing the wound, i. 731; Pouteau, Walther, and Jaeger's objection to dressing the wound, i. 731; Boyer, Sanson, Textor, and A. Cooper on dressing the wound, i. 731; accidents which may occur during and after the operation, i. 731; treatment of hæmorrhage, i. 731; of inflammation and suppuration, i. 731; the hæmorrhage occasionally, but rarely, fatal, i. 731; Copeland's objection to stuffing the rectum in cases of hæmorrhage after the operation, i. 731; Brodie on internal erysipelas following the operation, i. 732; ligature of the rectal fistula, i. 732; Luke on the advantages of the ligature, and on the mode of operating, i. 732; Dr. Nelken's instrument for applying the ligature, i. 732; South on the ligature of rectal fistula, i. 732; application of the leaden or silk-worm gut ligature in complete fistula, the internal opening not being high up, i. 732; Desault, Reisinger, Weidmann, Schreger, and Demme's apparatus for ligaturing complete fistula, i. 733; mode of employing Reisinger's apparatus, i. 733; treatment of fistula of the rectal sheath, i. 733; Mott on the treatment of fistula of the rectal sheath, i. 733; application of the ligature in an inwardly blind fistula, i. 733; re-application of the ligature sometimes necessary, i. 734; advantages of the respective operations by ligature and by cutting, i. 734;

treatment of rectal fistulæ by compression, i. 734; treatment of externally blind fistulæ, i. 734; *urinary fistula*, i. 737; definition and sub-division, i. 737; situation of the external and internal openings, and direction of the fistulous passage, i. 737; false urinary fistula, i. 737; causes and appearances, i. 737; incomplete internal urinary fistula, i. 737; causes and diagnosis, i. 738; incomplete internal fistula from ulceration of the mucous membrane of the urethra, or from abscesses in the lacunæ, i. 738; South and Brodie on incomplete internal urinary fistula, i. 738; complete urinary fistula, i. 738; situation of the internal and external openings, i. 738; causes, i. 739; symptoms and progress, i. 739; treatment of incomplete external fistula, i. 739; of incomplete internal fistula, i. 739; presence of stones in the sac of a blind fistula, i. 740; of complete urinary fistula, i. 740; complete urinary fistula opening on the penis, i. 740; symptoms, i. 740; treatment of the accompanying stricture, i. 740; of the fistula, i. 740: treatment of the fistula when callous, i. 740; Cooper and Dieffenbach on the treatment of callous fistulæ, i. 740; Cooper, Dieffenbach, Zang, and Freimann on the suture of urethral fistula, i. 741; Dieffenbach on the introduction of the running stitch, i. 741; Cooper, Earle, Alliot, Delpech, Ricord, and Dieffenbach on urethroplasty, i. 742; the operation of urethroplasty in fistulæ near the scrotum, i. 742; in large fistulæ in the middle or fore part of the penis, i. 742; in fistula close behind the prepuce, i. 743; in large openings immediately behind the glands, with deficient prepuce, i. 743; Charles Bell's operation for the restoration of the canal of the urethra, i. 744; causes, situation, and symptoms of complete urinary fistula in the hinder part of the urethra, i. 744; Brodie on the causes of fistula in perineo, i. 744; Brodie on the causes of perineal abscess, i. 744; treatment of urethral fistula, i. 745; Hunter, B. Bell, and Richter's objections to the use of the catheter in urethral fistula, 745; Brodie on the treatment of fistula in perinæo, i. 745, 746; operation for the callous fistula in perineo. i. 745; Brodie's case of malignant disease consecutive on neglected perineal fistula, i. 746; operation for the division of the stricture in great narrowing of the urethra, i. 746; South on the operation for the division of the stricture, i. 747; *recto-urethral and recto-vesical fistula*, i. 747; causes, symptoms, and treatment, i. 747; Dupuytren's treatment by the actual cautery or by caustic, i. 748; Jaeger on the division of the sphincter muscle, i. 748; Desault, Dupuytren, and Zang on the treatment of these fistulæ, i. 748; Astley Cooper's operation for recto-urethral fistula, i. 748; South's operation for recto-vesical fistula, i. 748; *vesico-vaginal fistula*, i. 750; causes, i. 750; symptoms, i. 751; diagnosis, i. 751; prognosis, i. 751; the instruments of Dzondi, Barnes, Schmitt, Burchard.Earle, and Dugés', i. 751; treatment of vesico-vaginal fistula, i. 751; Desault, Baines, Guthrie, Rognetta, Coxe, and Jaeger on the treatment by drawing off the urine and by compression, i. 752; Dupuytren, Lallemand, and Dieffenbach on cauterization as a means of cure, i. 752; Roonhuysen, Fatio, Voelter, Naegele, Schreger, and Wutzer on the use of the suture, i. 753; mode of applying the suture, i. 753; varieties of sutures, and their applition, by Naegele, Roux, Schreger, Ehrmann, Kilian, Lallemand, Deuber, and Dieffenbach, i. 755; puncture of the bladder above the pubes after the operation, i. 756; Dieffenbach and Wutzer on the after-treatment, i. 756; Jobert on the treatment of vesico-vaginal fistula by transplantation, i. 757; Dieffenbach's treatment of large fistulæ by drawing the mucous membrane together, i. 758; Dieffenbach's treatment of moderately large fistulæ, i. 758; Vidal's proposal to occlude the vulva, in complete destruction of the vagina and wall of the bladder, i. 759; Horner's proposal to draw down the uterus into the vagina, i. 759; Dr. Keith's case of vesico-vaginal fistula, i. 759; *recto-vaginal fistula*, i. 760; symptoms, i. 760; tendency to spontaneous cure, i. 760; Duparcque's case, i. 760; Duparcque on the indications in the treatment of this fistula, i. 760; Copeland's operation by the division of the sphincter ani, i. 761.

Flammant's, M., apparatus for fractured clavicle, i. 551.

Fleischmann's, M., description of the mucous bags beneath the tongue, ii. 406.

Fleming's, Mr., case of ligature of the external carotid for secondary hæmorrhage, ii. 233.

Fletcher's, Mr., instrument for œsophageal stricture, ii. 323.

Fleury's, M., case of simple serous cysts of the neck, ii. 695.

Fluctuation, occurrence and signs of, i 36.

Fontana, on the effects of viper bites, i. 353.

Foot, fracture of the bones of, i. 584; artificial, ii. 847; exarticulation of, at the ancle-joint, ii. 944; partial amputation of, ii. 947.

Ford, on the treatment of abscesses at the hip, i. 269; cases of spontaneous cure of aneurism, ii. 215.

Fore-arm, fracture of the bones of, i. 557;

dislocations of, i. 788; amputation through, ii. 926; exarticulation of, at the elbow, ii. 961.

FOREIGN BODIES, DISEASES DEPENDING ON THE PRESENCE OF, IN THE ORGANISM:— Definition and divisions, ii. 379; *foreign bodies introduced into the body from without*, ii. 380; *foreign bodies in the nostrils*, ii. 380; causes of retention, ii. 380; their removal, ii. 380; presence of balls from gun-shot wounds in the nostrils, ii. 380; when the foreign body cannot be removed it should be pushed backwards into the mouth, ii. 380; Astley Cooper's case of ball lodged in the frontal sinuses, ii. 380; *foreign bodies in the mouth*, ii. 380; are readily removed or got rid of by suppuration, ii. 380; South's case of a piece of tobacco-pipe lodged in the cheek, ii. 380; *foreign bodies in the œsophagus*, ii. 381; situation of the foreign body, ii. 381; South's cases of, ii. 381; symptoms, ii. 381; diagnosis often difficult, ii. 382; sensation of soreness in the throat after the extraction of the foreign body, ii. 382; South's case of fish-bone in the œsophagus, ii. 382; Monro's cases of halfpence in, ii. 382; Monro's case of a foreign body in a sac behind the œsophagus at its origin, ii. 382; removal of foreign bodies from the œsophagus, ii. 382; removal upwards, ii. 382; extraction of foreign bodies from the œsophagus by instruments, ii. 383; thrusting them down into the stomach, ii. 383; should not be attempted unless they be beyond the reach of the finger, ii. 383; Astley Cooper's case of fish-bone at the glottis, ii. 384; Brown's case of a piece of broken delf plate in the œsophagus, ii. 384; Tunnaley's case of a bristle in the œsophagus ii. 384; treatment when the foreign body has caused severe inflammation and diseased contraction of the œsophagus, ii. 384; consequences of foreign bodies in the œsophagus, ii. 384; passage of thin and pointed bodies through its walls and the neighbouring parts, ii. 385; cases requiring œsophagotomy, ii. 385; South's preference of tracheotomy to œsophagotomy, ii. 385; directions for the operation, ii. 385; Eckoldt's method, ii. 385; Vacca Berlinghieri and Bégin's directions for the operation, ii. 386; removal of the foreign body, ii. 387; after-treatment, ii. 387; *foreign bodies in the stomach and intestinal canal*, ii. 388; bulky bodies often pass away by the intestinal canal, pointed ones are retained, and cause inflammation and suppuration, ii. 388; Dr. Marcet and Dr. Barnes' cases of knife-swallowing, ii. 388; retention of bulky bodies and the symptoms they produce, ii. 389; obstruction of the ileum by a gall-stone, ii. 389; intestinal obstruction from lumps of carbonate of magnesia, and collections of cherry-stones, ii. 389; Langstaff's case of a madman who swallowed a silver spoon, ii. 389; consequences of the presence of pointed bodies in the intestines, ii. 390; general treatment in cases of foreign bodies in the stomach or intestines, ii. 390; Green's case of foreign body in the alimentary canal, ii. 390; extraction of the foreign body by gastrotomy or enterotomy, ii 390; Delpech's objections to these operations, ii. 390; Shoval's case of gastrotomy for the removal of a knife from the stomach, ii. 391; directions for gastrotomy, ii. 391; for enterotomy, ii. 391; enterotomy also advised for the relief of stricture and closure of the large intestines, for collections of fæces, ileus, and volvulus, ii. 391; *foreign bodies in the rectum*, ii. 392; Phillips' case of a stick in the rectum, ii. 392; M'Laughlan's case of a large plug of wood in the rectum, ii. 392; Johnson's case of obstruction of the rectum by a large collection of peas, ii. 392; Brodie's case of apple-core in the rectum, ii. 392; Welbank's case of part of a vertebra and rib in the rectum, ii. 392; symptoms of obstruction from foreign body in the rectum, ii. 392; abscesses by the side of the rectum, ii. 393; Brodie and Green's cases, ii. 393; Coulson's case of closure of the rectum from the presence of a foreign body, ii. 393; extraction of the foreign body from the rectum, ii. 393; Marchetti's case of swine's tail in the rectum, ii. 393; Custance's case of a blacking-pot in the rectum, ii. 393; Lawrence's case of neck of a wine-bottle in the rectum, ii. 394; *foreign bodies in the larynx and windpipe*, ii. 394; symptoms, ii. 394; Porter on the passage of foreign bodies into the larynx, ii. 394; De la Martinière's case of a foreign body in the windpipe, ii. 395; symptoms caused by a foreign body in the rima glottidis, ii. 395; by a foreign body loose in the wind-pipe, ii. 395; Bullock's case of a quartz pebble in the upper part of the larynx, ii. 396; symptoms of a foreign body in one of the bronchi, ii. 396; Sue, Dupuytren, Louis, Sutton, Paris, and Travers jun.'s cases of foreign bodies in the windpipe during a long period of time, ii. 396; the operation of laryngotomy or tracheotomy, ii. 398; cases requiring the operation, ii. 398; Stokes' cases of foreign bodies in the œsophagus inducing laryngeal symptoms, ii. 398; Cock's case of sixpence in the larynx, ii. 398; circumstances requiring the performance of laryngotomy, ii. 398; the operation must not be long delayed in angina laryngea, ii. 399; the operation useless in angina membranacea, ii. 399;

Nevermann's statistics of tracheotomy in laryngitis and tracheitis, ii. 399; Bretonneau, Trousseau, and Kirby on tracheotomy in croup, ii. 399; directions for the operation of laryngotomy, ii. 399; South on the practice of inserting a tube in the larynx after the operation, ii. 400; South's case of fistulous opening in the larynx from an attempt at suicide, ii. 400; division of the cartilage, ii. 400; removal of the foreign body, ii. 401; directions for tracheotomy, ii. 401; removal of the foreign body, ii., 401; removal of a foreign body from the bronchus, ii. 401; Brodie and Macrae's cases, ii. 401; Liston and Dickin's cases of foreign bodies in the bronchus, in which tracheotomy was performed, and the foreign body extracted with forceps, ii. 402; South on the necessity of examining the larynx and the rima with a probe after these operations for the extraction of foreign bodies, ii. 403; circumstances to be borne in mind respecting bronchotomy, ii. 403; dangers of tracheotomy, ii. 403; the operation of laryngo-tracheotomy preferable to tracheotomy, ii. 403; importance of careful observation during these operations, on account of the variety in the course of the great blood-vessels, ii. 404; *unnatural collections of natural products, in their proper cavities and receptacles*, ii. 404; *ranula*, ii. 404; definition and characters, ii. 404; Cline's case of impending suffocation from ranula, ii. 404; opinions on the nature of ranula, ii. 405; Cline's case of stone in one of the sub-maxillary ducts, ii. 405; chemical analysis of the fluid contained in ranula, ii. 406; Gmelin and Posselt's chemical analysis, ii. 406; Fleischmann's description of the mucous bags beneath the tongue, ii. 406; symptoms of a salivary calculus in Wharton's duct, ii. 406; treatment of ranula, ii. 406; Richter cauterizes ranula in children with lunar caustic, ii. 407; re-opening the duct in recent ranula, ii. 407; Dupuytren and South's modes of operating for ranula, ii. 407; *retention of bile*, ii. 408; symptoms, ii. 408; case of exceedingly enlarged gall-bladder from retention of bile, ii. 408; terminations of the disease, ii. 408; South on adhesion between and ulceration of the gall-bladder into the duodenum, ii. 408; treatment, ii. 408; opening the gall-bladder, ii. 409; *retention of urine*, ii. 409; seat of obstruction to the discharge of the urine, ii. 410; causes, ii. 410; symptoms of retention of urine in the ureters, ii. 410; dangers attendant on ischuria ureterica, ii. 410; Allan's case of retention of urine in the ureter, ii. 410; treatment of ischuria ureterica, ii. 411; symptoms of retention of urine in the bladder, ii. 411; terminations, ii, 411; South on bursting or gangrene of the bladder, as rare terminations of ischuria, ii. 411; Cheston's case of gangrene of the bladder from retention, ii. 412; South on the rare occurrence of opening of the urachus, ii. 412; symptoms of retention, when slowly produced, ii. 412; formation of sacs in the bladder, ii. 412; causes of retention of urine in the bladder, ii. 412; symptoms of paralytic retention, ii. 413; causes, ii. 413; prognosis, ii. 413; treatment, ii. 414; use of the catheter, ii. 414; local and general treatment, ii. 414; treatment of the quickly-occurring paralytic retention, ii. 414; contracted and irritable bladder, and its treatment, ii. 414; symptoms of retention of urine from inflammation, ii. 415; seat and causes of the inflammation, ii. 415; treatment, ii. 415; the catheter not to be used until antiphlogistic remedies have been employed, ii. 415; spasmodic retention of urine, ii. 416; symptoms, ii. 416; treatment, ii. 416; introduction of the catheter, ii. 416; retention of urine depending on stoppage of the urethra, ii. 416; causes, ii. 416; South on obstruction to the urine by calculi in the urethra, ii. 416; Hunter's case, ii. 416; Howship's case of distention of the bladder by blood, ii. 417; occasional obstruction to the urine, by blood flowing into the bladder after lithotomy, ii. 417; Lawrence's cases of worms and larvæ discharged from the urethra, ii. 417; foreign bodies introduced into the urethra, and there remaining, or slipping into the bladder, ii. 417; Tyrrell and Crisp's cases, ii. 417; Hunter on the expulsion of bougies by the contractions of the bladder, ii. 418; treatment of ischuria from calculi lying against the neck of the bladder, ii. 418; from blood, mucus, or calculi in the urethra, ii. 418; retention of urine from small stones in the orifice of the urethra, ii. 418; South on the removal of calculi from the urethra, ii. 418; treatment of retention from the pressure of the impregnated womb or other viscera, ii. 419; South's case of retention of urine from the pressure of an hydatid, ii. 419; ischuria from growths in the bladder, ii. 419; from swellings of the prostate, ii. 419; symptoms of inflammation of the prostate, ii. 419; suppuration and abscess of the prostate, ii. 419; Brodie on abscess of the prostate, ii. 420; treatment of retention of urine from inflammation of the prostate, ii. 420; introduction of the catheter, ii. 420; Lawrence, Brodie, and South on catheterism in inflammation of the pro-

state, ii. 420; Brodie on the treatment of abscess of the prostate, ii 421; swelling of the prostate from varicose veins, ii. 421; treatment, ii. 421; induration of the prostate, ii. 421; the discharge of a mucous or pus-like fluid in diseased conditions of the urinary passages, ii. 422; Astley Cooper, Brodie, and Lawrence on chronic enlargement of the prostate, ii. 422; Astley Cooper on the symptoms and post-mortem appearances in chronic enlargement of the prostate, ii. 423; Brodie and Astley Cooper on the characters of enlarged prostate, ii. 423; Brodie on the rare occurrence of ruptured bladder, from retention of urine in enlarged prostate, ii. 424; prognosis, ii. 424; treatment, ii. 424; Astley Cooper, Lawrence, and Brodie on the treatment of enlarged prostate, ii. 424; Brodie, Astley Cooper, and Lawrence on the treatment of retention of urine from enlarged prostate, and on catheterism in such cases, ii. 425; South on catheterism in enlarged prostate, ii. 425; treatment of complete retention in stricture, ii. 426; Amussat, Lallemand, Bégin, and South on the treatment of complete retention in stricture, ii. 427; forcible catheterism, and its dangers, ii. 427; Eckstrom's operation for cutting into the urethra in the perineum, ii. 428; directions for its performance, ii. 428; Lallemand, Bégin, and South on this operation, ii. 428; *of the catheter and its introduction*, ii. 429; form, shape, and consistence of the catheter, ii. 429; various kinds of catheters, ii. 429; South on the shape and thickness of the catheter, ii. 430; directions for the introduction of the catheter, ii. 430; the *tour de maitre*, ii. 430; introduction of the straight catheter, ii. 430; Amussat and Civiale on the introduction of the straight catheter, ii. 431; great care required in passing the catheter, ii. 431; obstacles to its introduction, ii. 431; signs of the catheter's having entered the bladder, ii. 431; retention of the catheter in the urethra, ii. 431; Lallemand on the retention of the catheter in the urethra, ii. 432; introduction of the female catheter, ii. 432: *puncturing the bladder*, ii. 432; causes requiring this operation, ii. 432; *puncturing the bladder above the pubes*, ii. 432; directions for the operation, ii. 432; after-treatment, ii. 433; changing the tubes inserted in the bladder, ii. 433: *puncturing the bladder through the rectum*, ii. 434; directions for the operation, ii. 434; *puncturing the bladder through the perineum*, ii. 434; directions for the operation, ii. 434; relative value of these operations, ii. 435; objections to these operations, ii. 435; Potter and South on puncturing the bladder, ii. 436: *the Cæsarean operation*, ii. 436; circumstances requiring the operation, ii. 437; Rigby on the circumstances authorizing the operation, ii. 437; the Cæsarean operation on a pregnant woman actually dead, the child being viable, ii. 437; danger of the operation, ii. 437; Michaelis on the doubtful character of the old cases in which the Cæsarean operation is reported to have been performed several times successfully on the same woman, ii. 438; Kayser on the statistics of the operation, ii. 438; Michaelis' case, in which the Cæsarean section was performed four times on the same woman, ii. 439; proper time for the performance of the operation, ii. 439; Rigby on the propriety of not operating until after labour has commenced, ii. 439; preparations for the operation, ii. 439; directions for the performance of the operation, ii. 440; dressing the wound, ii. 441; Godefroy's case of Cæsarean section, in which he sewed up the wound in the womb, ii. 442; Michaelis on the danger attending the effusion of the secretions from the wound into the belly, ii. 442; the after-treatment, ii. 442; Michaelis on the exhibition of opium, and the necessity of keeping the bowels open, after the operation, ii. 442; proposals to diminish the danger of the operation, ii. 442; Rietgen, Baudelocque, and Physick on the mode of performing the Cæsarean operation, ii. 443; Michaelis on the greater probability of success attending a repetition of the Cæsarean operation than in the first instance, ii. 444: *gastrotomy*, ii. 444; circumstances requiring the operation, ii. 444; circumstances of danger attending gastrotomy for extra-uterine pregnancy, ii. 444; symptoms of escape of the fœtus into the abdomen in tubular or ovarian pregnancy, ii. 445; the performance of the operation, ii 445: *cutting through the pubic symphysis*, ii. 445; circumstances requiring the operation, ii. 446; results, ii. 446; directions for the operation, ii. 446; after-treatment, ii. 447: *collection of natural fluids external to their proper cavities and receptacles: blood-swellings on the heads of newly-born children*, ii. 447; definition, seat, and characters, ii. 448; progress and termination of the tumour, ii. 448; suppuration of the blood-swelling, and perforation of the skull, ii. 449; causes and origin of blood-swellings, ii. 449; opinions as to the nature of the blood-swellings, ii. 450; appearances of the cavity of the blood-swellings when opened during life or after death, ii.

451 ; distinguishing characters of blood-swellings from other tumors on the head, ii 452 ; prognosis, ii. 453 ; treatment, ii. 453 ; opening the tumor, ii. 454 ; the opening not to be crucial, nor the entire length of the tumor, ii. 454 ; Hoere's case of simultaneous collection of blood between the pericranium and the skull, and the dura mater and skull, the latter being fissured, ii. 454 : *hæmatocele*, ii. 455 ; definition and divisions, ii. 455 ; Mayo on hæmatocele, ii. 455 ; causes, ii. 455 ; Pott and Brodie on effusion of blood into the cellular tissue of the scrotum, ii. 455 ; treatment, ii. 455 ; causes of hæmatocele in the vaginal tunic, ii. 456 ; diagnosis, ii. 456 ; Brodie on hæmatocele complicated with hydrocele, ii. 456 ; South on hæmatocele following the operation for hydrocele, ii. 456 : Brodie's case of hæmatocele, in which the tunica vaginalis ruptured, ii 456 ; Astley Cooper's case of hæmatocele, ii. 456 ; treatment, ii. 456 ; by operation, ii. 456 ; South on dispersing the blood in hæmatocele of the vaginal tunic, ii. 456 ; Astley Cooper's case of hæmatocele of 17 years' duration, ii. 456 ; South on the occurrence of suppuration, if the effused blood be not soon absorbed, ii. 457 ; hæmatocele of the testicle, and its treatment, ii. 457 ; Pott and Curling on hæmatocele of the spermatic cord, ii. 457 : *outpouring of blood into the cavities of joints*, ii. 457 ; causes, ii. 457 ; Hey's case, ii. 457 ; treatment, ii. 457 : *collections of diseased products : dropsy of the mucous sacs*, ii. 458 ; characters, ii. 458 ; Mayo on dropsy of the bursæ mucosæ, ii. 458 ; Mayo and South on the formation of bursæ from pressure, ii. 458 ; causes of dropsy of the mucous sacs, ii. 458 ; condition of the diseased part, ii. 458 ; Cruveilhier on encysted swellings, ii. 458 ; South on partial enlargements of the sheaths of tendons, ii. 459 ; dropsy of the bursæ most frequent on the knee-cap, ii. 459 ; characters, ii. 459 ; degeneration of mucous sacs, and their treatment, ii. 459 ; South on *housemaid's knee*, ii. 459 ; treatment, ii. 459 ; by operation, ii. 460 ; Dupuytren on the operative treatment of encysted swellings, ii. 460 ; Lenoir on dropsy of the bursæ in the sole of the foot, ii. 460 ; Travers' case of suppuration of the bursa on the knee-cap, ii. 461 ; South on the treatment of dropsical bursæ, ii. 461 ; *dropsy of the joints*, ii. 461 ; definition and characters, ii. 461 ; causes and progress, ii. 461 ; Brodie on hydrarthrus, ii. 462 ; prognosis, ii. 462 ; treatment, ii. 462 ; by operative proceeding, ii. 462 ; South's objections to the operation, ii. 462 ; after-treatment, ii. 462 ; Bonnet, Velpeau, and South on injections of iodine in hydrarthrus, ii. 463 : *water in the head, and cleft-spine*, ii. 464 ; definition and varieties of hydrocephalus, ii. 464 ; seat of the fluid in hydrocephalus externus, ii. 464 ; effusion of the fluid between the membranes and the skull, and in the ventricles of the brain, ii. 464 ; condition of the parts in congenital hydrocephalus internus, ii. 465 ; nature and characters of spina bifida, ii. 465 ; spina bifida may be unconnected with hydrocephalus, ii. 465 ; Gall and Chesman's cases, ii. 465 ; state of the cerebral and spinal functions in hydrocephalus and spina bifida, ii. 466 ; Fisher on the origin of spina bifida, ii. 466 ; Hewett on the connexion between the cord or the nerves and the walls of the sac in spina bifida, ii. 467 ; treatment, ii. 467 ; Dr. Copland on puncturing the brain in chronic hydrocephalus, ii. 467 ; Abernethy, Astley Cooper, and Hewett on puncturing spina bifida, ii. 468 ; Dubourg, Tavignot, and Beynard on the treatment of spina bifida by closing the sac, ii. 469 : *the collection of serous and purulent fluids in the cavity of the chest,—hydrothorax, and empyema*, ii. 469 ; symptoms, ii. 469 ; characters by mensuration, percussion, and auscultation, ii. 470 ; physical phenomena of pleuritic effusion, ii. 471 ; Hirtz on the physical phenomena of pleuritic effusion, ii. 472 ; causes of effusion into the chest, ii. 473 ; circumstances requiring and admitting of paracentesis thoracis, ii. 473 ; mode of operating, ii. 473 ; mode of operating by opening the chest with a cut, ii. 474 ; place where the incision should be made, ii. 474 ; South's objections to opening abscess of the lung, ii. 475 ; dressing and after-treatment, ii. 475 ; puncturing the chest with a trocar, ii. 475 ; various plans recommended for preventing the entrance of air, ii. 476 ; after-treatment, ii. 476 ; relative value of the two operations, ii. 476 ; mode of cure after the operation, ii. 477 ; Dr. Davies on the operation for empyema, ii. 478 ; *dropsy of the pericardium*, ii. 478 ; symptoms and characters, ii. 478 ; Laennec, Piorry, and Gendrin on the physical characters of dropsy of the pericardium, ii. 479 ; condition of the parts in hydro-pericardium, ii. 479 ; South on suppuration of the pericardium, ii. 479 ; treatment by operation very dangerous, ii. 479 ; mode of operating, ii. 480 ; *the accumulation of serous and purulent fluids in the mediastina*, ii. 481 ; symptoms, ii. 481 ; treatment by operation, ii. 481 ; description of the operation, ii. 481 : dressing and after-treatment. ii. 481 ; *dropsy of the belly*, ii. 482 ; varie-

ties, ii. 482; treatment by tapping, ii. 482; tapping only a palliative operation, ii. 482; place where it should be performed, ii. 482; Astley Cooper on tapping in the linea alba, ii. 483; cases in which another place should be selected for the operation, ii. 483; performance of the operation, ii. 483; South on the propriety of passing the catheter before tapping, ii. 484; South on the propriety of ascertaining the condition of the womb before tapping, ii. 484; South on the operation of tapping, ii. 484; dressing the wound, ii. 484; occurrence of hæmorrhage, ii. 485; South's case of wound of the epigastric artery during the operation of tapping, ii. 485; South's case of venous hæmorrhage during the operation of tapping, ii. 485; Watson's cases of hæmorrhage during the operation of tapping, ii. 485; after-treatment, ii. 485; remarks on puncturing in different places, ii. 486; Buchanan's operation of puncturing the cavity of the abdomen through the bladder, ii. 486; ovarian dropsy, ii. 486; diagnosis, ii. 486; puncturing ovarian dropsy only palliative, ii. 487; Ollenroth, Le Dran, Littre, Chopart, Desault, and Dzondi's modes of operating, ii. 487; King, West, Jeaffreson, De la Porte, and Morand on the extirpation of the ovary, ii. 487; mode of operating, ii. 488; Recamier's fatal operation, ii. 488; Brown's treatment of ovarian dropsy, ii. 488; Bonfils and Camus' mode of proceeding, ii. 488; Southam on the effects of paracentesis in ovarian dropsy, ii. 488; the small and the large operations for the extirpation of ovarian dropsy, ii. 489, the small operation first suggested by Dr. W. Hunter, ii. 489; Jeaffreson, King, and West's cases, ii. 489; M'Dowall, Lizars, and Clay on the large operation, ii. 489; relative value of the operations for ovarian dropsy, ii. 489; South on the relative value of the small and large operations for ovarian dropsy, ii. 490; Phillips, Jeaffreson, and Stafford Lee on the statistics of these operations, ii. 490; Southam on the nature of ovarian disease, ii. 491; Bonfils, Camus, Locock, Astley Cooper, and Schmucker's cases of spontaneous rupture of ovarian cyst, ii. 491; Astley Cooper's case of ovarian dropsy, in which the fluid was discharged by ulceration of the navel, ii. 492; Sutton's case of ovarian dropsy, with discharge of hair by the wound made in tapping, ii. 492; Ashwell and Southam on the extirpation of ovarian cysts, ii. 492; cases in which tapping was repeatedly performed, ii. 493; Dohlhoff's case of encysted abscess of the abdomen, ii. 493; abdominal dropsy complicated with pregnancy, ii. 494; situation in which tapping should be performed, ii. 494; *dropsy of the womb,—hydrometra*, ii. 494; symptoms, ii. 494; distinctions between hydrometra and pregnancy, ii. 494; dropsy of the pregnant womb, ii. 494; symptoms, ii. 495; causes of dropsy of the unimpregnated womb, ii. 495; paracentesis uteri, ii. 495; *tympanitis*, ii. 495; treatment by paracentesis, ii. 495; mode of operating, ii. 495; *hydrocele*, ii. 496; definition, ii. 497; varieties, ii. 497; causes of collection of water in the cellular tissue of the scrotum, ii. 497; symptoms and characters of hydrocele of the tunica vaginalis, ii. 497; South on the characters of hydrocele, ii. 497; Astley Cooper and Brodie's cases of hourglass hydrocele, ii. 497; Astley Cooper and South on the situation of the testicle in hydrocele, ii. 498; Cline and Brodie's cases of large hydroceles, ii. 498; South and Astley Cooper on the characters of the serum in hydrocele, ii. 498; diagnosis between hydrocele and diseases of the testis, ii. 498; South on the complications of hydrocele, ii. 498; causes, ii. 498; Rochoux, Velpeau, Blandin, Pigné, and Gausseil on hydrocele caused by gonorrhea, ii. 498; prognosis, ii. 499; treatment, ii. 499; Brodie, Astley Cooper, and South on the spontaneous cure of hydrocele, ii. 499; situation in which the puncture of the hydrocele is to be performed, ii. 500; the operation of tapping, ii. 500; Travers, Lewis, and South on the treatment of hydrocele by punctures, ii. 500; tapping with a lancet, ii. 501; varying consistence of the fluid in hydrocele, ii. 501; treatment after tapping, ii. 501; Astley Cooper on the radical cure of hydrocele by exercise after tapping, ii. 501; South on the impropriety of any other operation than tapping in old people, ii. 501; radical cure of hydrocele, ii. 501; by external stimulant applications, ii. 502; Kinder Wood's operation of excising a portion of the tunica vaginalis, ii. 502; the radical cure by incision, ii. 502; mode of operating, ii. 502; after-treatment, ii. 502; if during the operation the testicle be found hardened, must be extirpated, ii. 503; hydatids of the testicle also to be removed, ii. 503; the operation by injection, ii. 503; mode of operating, ii. 503; after-treatment, ii. 503; strength of the injection should vary according to the sensibility of the patient, ii. 503; various fluids used as injections, ii. 503; South on the iodine injection in hydrocele, ii. 504; occasional failure of the injection to cure the disease, ii. 504; Astley Cooper on the cause of the failure, ii. 504; Brodie and Everard Home's cases of relapse of hydrocele after a long time, ii. 504; South on suppuration of the tunica vaginalis after the operation by injection, ii. 504; South on the treatment when the cellular tissue of the scrotum is injected by mistake, instead of the tunica vaginalis, ii. 504; treatment of hydrocele by the introduction of a seton, ii. 504; Holbrook, Onsenoort, Green, and South on the treatment of hydrocele by the seton, ii. 505; use of a tent, ii. 505; treatment by caustic, ii. 505; Hesselbach on the treatment of hydrocele by caustic, ii. 506; cutting away the vaginal tunic, ii. 506; Boyer, Dupuytren, Textor, Balling, and South on this operation, ii. 506; relative value of these operations, ii. 506; *congenital hydrocele,* ii. 507; characters and natural cure, ii. 507; *congenital hydrocele of women,* ii. 507; period of its occurrence, ii. 507; treatment, ii. 508; Viguerin and Desault's plans, ii. 508; treatment by injection dangerous, ii. 508; varieties of congenital hydrocele, and their treatment, ii. 508; *hydrocele complicated with rupture,* ii. 509; symptoms, ii. 509; diagnosis, ii. 509; treatment, ii. 510; when the rupture is reducible, ii. 510; when irreducible, ii. 510; South on the treatment of hydrocele complicated with rupture, ii. 511; *hydrocele of the general vaginal tunic,* ii. 511; varieties, ii. 511; characters and treatment, ii. 511; *encysted hydrocele,* ii. 511; characters and treatment, ii. 511; the operation, ii. 511; *formation of stony concretions in the fluids of the body,* ii. 512; are formed in the urine, bile, saliva, and fæces, ii. 512; *urinary calculus:* Magendie, von Walther, Austin, Wetzlar, Willis, and Jones on the formation of calculi, ii. 513; general constituents of calculi, ii. 517; other and more rare constituents, ii. 517; Taylor on the rarity of carbonate of lime calculi, ii. 518; *uric acid and urate of ammonia,* ii. 518; the combination of uric acid with ammonia, and its precipitation in the free state on the cooling of the urine, ii. 518; the development of free acids in the urine, ii. 519; *oxalate of lime,* ii. 519; frequently forms the nucleus of a calculus, but not uncombined, ii. 519; a calculus of almost pure oxalate of lime has been met with, ii. 519: Prout and Walther on the origin of oxalic acid in the urine, ii. 519; presence of free oxalic acid in the urine, ii. 520; combinations of oxalic acid, ii. 520; *cystin,* ii. 521; calculi of cystic oxide rare, ii. 521; usually consist entirely of this substance, but occasionally met with as nuclei of other calculi, ii. 521; formation of cystic oxide calculi, ii. 521; chemical composition, ii. 521; *xanthic oxide, uric oxide,* ii. 521; of very rare occurrence, ii. 521; chemical composition, ii. 521; never occurs in solution, or as a precipitate from the urine, ii. 521; *phosphate of ammonia and magnesia,* ii. 522; causes of its formation, ii. 522; Jones on the phosphatic diathesis, ii. 522; connecting material of calculi, ii. 522; causes of the production of gravel and calculi, ii. 522; remote causes, ii. 522; Taylor on the calculi of children, ii. 523; foreign bodies in the bladder act as the nuclei of calculi, ii. 523; foreign bodies rarely coated with uric acid, ii. 524; South on foreign bodies as the nuclei of stones, ii. 524; Astley Cooper, Brodie, and Everard Home's cases, ii. 524; A. White and Arnott's cases of foreign bodies in the vagina, the bladder injured, and formation of calculi, ii. 524; varieties of calculi, ii. 525; characters, ii. 525; characters of uric acid calculi, ii. 525; of urate of ammonia, ii. 525; of mulberry stones, ii. 525; of hempseed calculi, ii. 526; of the earthy phosphates, ii. 526; of the phosphate of lime, ii. 526; of the fusible stone, ii. 526; of the cystic oxide, ii. 526; of xanthic oxide, ii. 526; of carbonate of lime, ii. 526; physical characters of calculi, ii. 526; division of calculi according to their chemical composition, ii. 527; frequency of the different kinds of calculi, ii. 527; *amorphous urinary sediments,* ii. 528; Dr. Prout on lithic or uric acid sediments, ii. 528; characters of yellow sediments, ii. 528; of red or lateritious sediments, ii. 528; of pink sediments, ii. 528; white lithate or urate of soda sediment, ii. 529; characters and accompanying symptoms of the phosphatic sediments, ii. 529; causes of the phosphatic sediments, ii. 530; oxalate of lime sediment, ii. 530; characters of the urine in cystic oxide calculus, ii. 530; *gravel,* ii. 530; definition and characters, ii. 530; Magendie on hairy gravel, ii. 530; symptoms of gravel, ii. 531; Prout on the characters and symptoms of crystallized uric acid gravel, ii. 531; Prout on the crystallized phosphatic sediments, ii. 532; Prout on the rarity of crystallized oxalate of lime gravel, ii. 532; symptoms of the oxalic diathesis, ii. 532; causes and treatment, ii. 533; treatment of gravel, ii. 533; of uric acid gravel, ii. 533; Wetzlar, Jones, Wilson Philip, and Brodie on the treatment of uric acid gravel, ii. 534; Prout on the treatment of a fit of the gravel, ii. 535; Jones on the treatment of uric acid gravel, ii. 535; treatment of [illegible]

t of cystic oxide gravel, ii. 537; Prout and Jones on the treatment of the oxalate of lime diathesis, ii. 537; Prout and Jones on the treatment of the phosphatic diathesis, ii. 538; *stones in the kidneys,* ii. 539; situation, ii. 539; Prout on the formation of uric acid calculi in the kidneys, ii. 540; Brodie on the connexion between uric acid calculi and gout, ii. 540; Prout and Brodie on renal calculi of oxalate of lime, ii. 540; Prout on renal calculi of cystic oxide, ii. 541; Prout on the rarity of phosphatic renal calculi, ii. 541; diagnosis, ii. 541; symptoms, ii. 541; Brodie on the symptoms of renal calculi, ii. 541; Astley Cooper and Brodie's cases, ii. 541; progress of stone in the kidney, ii. 541; Brodie on the passage of renal calculi into the bladder, ii. 541; Hevin, Astley Cooper and Brodie's cases of renal calculi communicating with abscess in the loins, ii. 542; Crisp's case of fracture of a renal calculus by sudden exertion, ii. 542; treatment, ii. 542; removal of the calculus by nephrotomy, ii. 542; directions for the operation, ii. 542; Brodie and South on the treatment of renal calculi, ii. 542; Prout on the treatment of nephritis complicating renal calculi, ii. 542; Brodie on gouty inflammation of the kidneys, ii. 543; *stone in the ureters,* ii. 543; symptoms, ii. 543; treatment, ii. 543; Brodie on the symptoms of stone in the ureter, ii. 543; Brodie and Travers' cases of impaction of calculi in the ureters, ii. 544; Cline and Astley Cooper's cases of suppuration of the kidney from impaction of calculi in the ureters. ii. 544; Astley Cooper on the treatment of calculi in the ureters, ii. 544; *stone in the bladder,* ii. 544; origin and varieties, ii. 544; Brodie on the prevalence of calculi in different classes of society, and at different ages, ii. 545; Smith on the statistics of lithotomy, ii. 545; Copland Hutchinson on the rarity of calculus among seamen, ii. 545; forms of calculi in the bladder, ii. 545; characters and situation, ii. 546; sacculated and adherent calculi, ii. 546; Taylor on hourglass calculi, ii. 546; Cline, Mayo, Astley Cooper. Smith, and Cheselden's cases of large calculi, ii. 546; Martineau's cases of very small stones, ii. 547; Astley Cooper's case of a great number of calculi in the bladder, ii. 547; Pott's case of fusible calculus in a vesical rupture, ii. 547; Brodie's case of encysted calculus, ii. 547; Wickham's case of calculus enclosed in a bag of lymph encrusted with calculous matter, ii. 548; Brodie, Prout, and Crosse on the spontaneous breaking up of calculi in the bladder, ii. 548; symptoms of vesical calculus, ii. 548; Prout on the symptoms of vesical calculus. ii. 550; sounding the bladder, ii. 550; Klein, Brodie, and South on sounding, ii. 550; Brodie and South on the existence of calculous symptoms, without the presence of a stone in the bladder, ii. 551; South on the simulation of calculus by vesical polypus, ii. 551; measuring the size of the calculus, ii. 551; South on measuring the calculus, ii. 551; various modes of treatment, ii. 552; internal use of stone-solvents, ii. 552; empirical remedies, ii. 552; efficacy of stone-solvents, ii. 552; Liston's case of partial solution of a stone in the bladder, ii. 553; injection of solvents into the bladder, ii. 553; directions for the use of solvent injections, ii. 553; difference of opinion as to the value of these modes of treatment, ii. 553; Pelouze's experiments, ii. 554; Prout and Brodie on the use of stone-solvents, ii. 554; dissolving stone by means of the galvanic pile, ii. 555; the apparatus and its application, ii. 555; *extraction of the stone through the urethra,* ii. 555; by dilatation, ii. 555; principally applicable to females, ii. 555; mode of effecting the dilatation, ii. 555; Brodie on the dilatation of the urethra, ii. 556; Astley Cooper, Liston and Brodie on the dilatation of the female urethra, ii. 556; *crushing the stone,—lithotrity,* ii. 557; Gruithuisen, Elderton, and Sanctorius' lithotritic instruments, ii. 558; case of the Monk of Citeaux, ii. 558; General Martin's case, ii. 558; improvement of lithotritic instruments, ii. 559; three classes of lithotritic instruments, ii. 559; relative value of these instruments, ii. 560; advantages and disadvantages of the three-limbed perforating forceps, ii. 560; of Jacobson's instrument, ii. 560; of Heurteloup's percuteur, ii. 560; treatment prior to the operation, ii. 561; position of the patient, ii. 561; mode of operating, ii. 561; with the three-limbed perforating forceps of Civiale and Leroy, ii. 562; with Jacobson's instrument, ii. 563; with Heurteloup's percuteur, ii. 563; duration of a lithotriptic sitting, ii. 564; treatment after the operation, ii. 564; escape of sand and calculous fragments, ii. 564; arrest of fragments in the urethra, ii. 565; breaking up the fragments in the bladder, ii. 565; treatment of fragments of calculus fixed in the urethra, ii. 565; by extraction, ii. 566; removal by incision, ii. 566; examination of the bladder when the calculous symptoms have ceased, ii. 566; lithotrity in women, ii. 566; *cutting for the stone,—lithotomy,* ii. 568; definition, ii. 568; should be performed early, ii. 568; circumstances contra-indicating the operation, ii. 568; Cline, Attenburrow and Astley Cooper's cases of old men operated on for stone, ii. 569; Keate, Hunter and Civiale's operations on infants, ii. 569; Green's case of lithotomy in a fat man of 50 years of age, ii. 569; preparation of the patient for the operation, ii. 569; cutting for the stone in man, ii. 570; with the little or Celsian apparatus, ii. 570; mode of operating, ii. 570; objections to the operation, ii. 571; cutting for the stone with the great apparatus, ii. 571; mode of operating, ii. 571; advantages of this operation over the little apparatus, ii. 572; the high operation, ii. 572; mode of operating, ii. 573; modifications of the operation, ii. 574; dressing the wound, ii. 575; the prevention of infiltration of urine from this operation, ii. 575; treatment of the wound for some days, ii. 576; untoward circumstances during and after the operation, ii. 576; advantages and disadvantages of the operation, and cases in which it is applicable, ii. 577; Cheselden on the high operation, ii. 577; the lateral operation, ii. 578; Rau's mode of operating, ii. 579; Cheselden's operation for stone, ii. 580, 585; preparations for the operation, ii. 580; South on the binding a patient prior to the operation, ii. 580; mode of operating, ii. 581; Brodie's case of encysted calculus removed by the lateral operation, ii. 581; South's case of stone undetected by the sound during eight years, ii. 581; Brodie and South on the external incision, ii. 582; Scarpa on the division of the prostate, ii. 583; Key and Liston's modes of operating for stone, ii. 584; Dr. James Douglas and Sharp on Cheselden's operation, ii. 586; Douglas on the dissection of the parts concerned in this operation, ii. 587; Martineau and Bromfield's operations, ii. 587; Brodie on the section of the prostate and bladder, ii. 588; use of Langenbeck's knife, ii. 589; Thomas Blizard, Astley Cooper, and Tyrrell on the section of the prostate, ii. 590; extraction of the calculus, ii. 590; use of the cutting gorget, an improvement on Cheselden's blunt gorget, ii. 591; Cline's gorget, ii. 592; Scarpa's gorget, ii. 592; Astley Cooper on opening the membranous part of the urethra, ii. 592; South on the use of the cutting gorget, ii. 593; objections to the cutting gorgets, ii. 593; South's opinion that these objections are groundless, ii. 593; Le Cat and Pajola's mode of operating for stone, ii. 594; objections to the operation, ii. 595; Frère Côme's operation with the *lithotome caché*, ii. 595; disadvantages of the instrument, ii. 596; Boyer's mode of using Frère Côme's lithotome, ii. 596; Dupuytren's bilateral section, ii. 596; mode of operating, ii. 596; Béclard's modification of the operation, ii. 597; advantages and disadvantages of the operation, ii. 597; extent of the incision in the prostate and neck of the bladder, ii. 598; extraction of the stone, ii. 599; obstacles to the extraction of the stone, ii. 599; *taille en deux tems*, ii. 600; Brodie and South on contraction of the bladder during lithotomy, ii. 600; extraction of the stone when enclosed by a contracted bladder, ii. 601; of an encysted stone, ii. 601; of a stone lodging in the ureter, and projecting into the bladder, ii. 601; of a stone lying in a hollow, ii. 601; of a stone covered with fungosities, ii. 601; of a brittle and easily-breaking stone, ii. 601; dressing the wound, ii. 602; hæmorrhage during the operation, ii. 602; from the branches of the superficial perineal artery, ii. 602; from the inferior hæmorrhoidal, ii. 602; from the internal hæmorrhoidal, ii. 602; from the internal pudic, ii. 602; from the vesical, ii. 602; treatment of the hæmorrhage, ii. 602; Erard, Dupuytren, and von Graefe's compressors, ii. 603; Shaw's case of fatal hæmorrhage in lithotomy, from wound of the dorsal artery of the penis, ii. 603; Brodie on the effects of hæmorrhage in lithotomy, ii. 603; South on the treatment of hæmorrhage during and after the operation, ii. 603; Brodie's case of fatal venous hæmorrhage in lithotomy, ii. 603; symptoms of hæmorrhage into the bladder after the operation, ii. 603; South on secondary hæmorrhage after lithotomy, ii. 604; Brodie, Earle, Travers, Green, and South's cases, ii. 604; wounding the rectum, ii. 605; South on wounding the rectum, ii. 606; convulsions and fainting, ii. 606; after treatment, ii. 606; South on the treatment to be adopted after the operation for lithotomy, ii. 607; causes and treatment of inflammation after the operation, ii. 609; of spasm, ii. 609; Key on suppurative inflammation of the cellular tissue surrounding the bladder the most frequent cause of death after lithotomy, ii. 609; Brodie on the dangerous symptoms which follow the incision of the prostate extending into the loose cellular texture surrounding the neck of the bladder, ii. 609; treatment of the consecutive hæmorrhage, ii. 610; abscesses about the neck of the bladder, ii. 611; incontinence of urine and impotence, ii. 611; disposition to lithogenesis, ii. 611; opening the bladder from the perineum, ii. 611; Foubert's operation, ii. 611; cutting for the stone through the rectum, ii. 612; Brodie on the recto-vesical operation, ii. 612; Solly's case of recto-vesical operation, ii. 612; Sanson's two modes of operating, ii. 612; description of the operation, ii. 613; modifications of the operation, ii. 614; after-treatment, ii. 614; advantages and disadvantages of the recto-vesical operation, ii. 615; results of recto-vesical lithotomy, ii. 615; Vacca Berlinghieri and Dupuytren's operations for stone, ii. 616; *cutting for the stone in women*, ii. 616; various modes of operating, ii. 617; Astley Cooper on the symptoms of stone in women, ii. 617; Brodie on the expulsion of small calculi from the bladder in women, ii. 617; Brodie and Astley Cooper's cases of ulceration of the bladder and vagina by the pressure of large calculi, ii. 617: cutting for the stone in women by the lateral operation, ii. 617; mode of operating, ii. 617; the horizontal cut on one or both sides, ii. 618; Liston's operation, ii. 618; the vertical cut upwards, ii. 618; Brodie's modification of the vertical cut upwards, ii. 618; advantages of the vertical cut upwards, ii. 619; the vertical cut downwards, ii. 619; the cut below the pubic symphysis, ii. 619; objections to the operation, ii. 620; Lisfranc's vestibular cut, ii. 620; mode of operating, ii. 620; objections to the operation, ii. 620; von Kern's operation, ii. 620; the vagino-vesical cut, ii. 621; advantages of this operation, ii. 621; Astley Cooper, Brodie, Liston, Hey, and South on the incontinence of urine consequent on the operation, ii. 621; South on dilatation of the female urethra for the extraction of calculi, ii. 622; opening the bladder above the pubic symphysis, ii. 622; *comparison of lithotomy and lithotrity*, ii. 622; equality of the possible evils after the two operations, ii. 623; possible evils from lithotrity, ii. 623; Liston on the breaking or bending of lithotritic instruments in the bladder, ii. 623; Brodie on the occurrence of hæmorrhage and of rigors after lithotrity, ii. 623; comparison of the results in lithotomy and lithotrity, ii. 624; cases in which lithotrity is inapplicable, ii. 624; lithotomy preferable for children, ii. 624; lithotrity preferable in advanced age, females, and in very stout persons, ii. 624; stones of moderate size, and round or oval in shape, best for crushing, ii. 624; cases in which lithotrity is preferable, and cases in which lithotomy should be performed, ii. 625; stricture of the urethra only a temporary contra-indication to lithotrity, ii. 625; palsy of the bladder not a contra-indication, ii. 625; Key on the advantages and applicability of lithotrity, ii. 625; Key on lithotrity with reference to the size of the calculus, ii. 626; Key on the applicability of lithotrity or lithotomy according to the age of the calculous patient, ii. 626; Key on the requisite condition of the bladder for the operation of lithotrity, ii. 627; Key on irritability of the bladder, ii. 627; Brodie, Liston, and South on the cases in which lithotrity should be performed, and on those in which lithotomy should be preferred, ii. 627; *stone in the urethra*, ii. 630; consequences of the impaction of stones or other foreign bodies in any part of the urethra, ii. 630; Travers' case of calculus in the urethra, ii. 630; Home's case of retention of urine, and consequent mortification from the impaction of calculi in the urethra, ii. 630; Liston's case of a small brass ring encircling the penis, ii. 630; symptoms of stone at the neck of the bladder, ii. 630; treatment and removal by operation, ii. 630; South on the treatment of stone in the urethra, ii. 631; symptoms and treatment of stone in the membranous part of the urethra, ii. 631; of stone in the spongy part of the urethra, ii. 631; in the fossa navicularis, ii. 631; the entire urethra, in rare cases, blocked up with calculi, ii. 632; South on the extraction of calculi in the urethra in front of the scrotum without incising the canal, ii. 632; *urinary calculi external to the urinary passage*, ii. 632; are met with in the perineum or scrotum from the destruction of the walls of the urethra, ii. 632; consequences, ii. 632; may also occur in the vagina or rectum by the destruction of their parietes, ii. 632; Vincent's case of calculi in the perineum, ii. 632; Vincent's case of calculi between the prepuce and glans penis, ii. 633; treatment of these calculi, ii. 633; *prostatal stones*, ii. 633; varieties, ii. 633; Astley Cooper's case, ii. 634; treatment by operation, ii. 634; Green's case of encysted stone, ii. 634; Travers' case of stone broken up under the use of a constitutional stone-solvent, ii. 634; statistics of the operations of lithotomy at St. Thomas' hospital from 1800 to 1846, ii. 635; *lithectasy, cystectasy*, ii. 642: object of the operation, ii. 642; originally proposed by John Douglas, ii. 642; Dr. Arnott and Astley Cooper's case, ii. 643; Elliott, Dr. Wright, and Fergusson's cases, ii. 643.

FORSTER on the cure of syphilis by the chloride of gold and silver, i. 670.

FOUBERT'S operation of opening the bladder through the perineum, ii. 611.

FOULLIAY'S plan of amputating the thigh with the flap from before, ii. 909.

FOURNIER'S case of foreign body in the heart, i. 455.

FOY'S analysis of scirrhus, ii. 763.

FRACTURES OF BONES IN GENERAL:—Definition of a fracture, i. 496; nature and varieties of fractures, i. 496; sub-division of fractures into complete and incomplete, i. 497; Boyer's objection to this sub-division, i. 497; Meding's experiments, i. 457; causes, local and general, of fractures, i. 497; influence of external

violence, i. 497; the contrecoup, i. 497; opinions of Bichat, Mercier, and Pigné on the changes which the substance of bone undergoes in advanced age, i. 497; diagnosis of fracture, i. 498; Lisfranc on the use of the stethoscope in the diagnosis of fractures, i. 498; prognosis, i. 498; union of the ends of a fractured bone, i. 499; formation of callus, i. 499; Dupuytren on the two periods in the formation of bone, i. 499; John Hunter on the period of union, and the manner in which it takes place in simple fracture, i. 500; Breschet and Villermé on the re-union of fractures, i. 500; Breschet and Villermé on the double formation of bony substance in fracture, i. 501; Miescher, Weber, Breschet, Villermé, Meding, Scarpa, and Dupuytren on the production of callus, i. 501; summary of Miescher's views on the formation of the primary and secondary callus, i. 501; formation of an artificial unnatural joint, from an imperfect condition of the callus, i. 502; fracture of the neck of the femur within the capsule, of the olecranon, knee-cap, and heel-bone, unites generally by a tough cellular intersubstance, i. 502; South on the causes of the want of bony union in such cases, i. 503; partial union of broken bone from imperfect adaptation, i. 503; treatment of fractures, i. 503; setting the fracture, i. 503; application of the fracture-apparatus, i. 503; varieties of splints, i. 503; rejection of fracture-plasters, i. 504; compresses should not be applied on the seat of fracture, i. 504; South on the non-necessity for bandages in fractures, i. 504; Cheselden, John Lawrence, and South on the immovable apparatus for fractures, i. 504, 505; Smee's experiments, i. 505; Tavignot on the use of oil varnish applied over the starch bandage in fractures in young children, i. 505; the simple contentive apparatus in transverse fractures, and such as are not very oblique, i. 506; position of the limb during extension and counter-extension, i. 506; South on the position of the limb when stiffness of the joint is anticipated, i. 506; treatment of the fracture after it has been set, i. 506; South on the after-treatment of the fracture, i. 507; general treatment, i. 507; South on the impropriety of setting a fracture before the lapse of a few days, i. 507; South on the immediate management of fractured clavicle, and of oblique fractures, i. 508; severity of the symptoms in compound fractures, i. 508; setting a compound fracture, i. 508; enlarging the wound, if the projecting piece of bone be firmly girt by it, or sawing off the protruding portion, i. 508; removal of splinters, i. 508; treatment during suppuration, i. 509; wounds of large vessels in compound fracture, i. 509; causes and treatment of mortification in compound fracture, i. 509; complication of compound fracture with delirium tremens—symptoms and treatment, i. 509; South's definition of a compound fracture, i. 509; John Hunter on the consequences of compound fractures, i. 509; Astley Cooper on the effect of compound fractures on the constitution, and on the reduction of a compound to a simple fracture, i. 510; Miescher's experiments to induce suppuration in compound fractures, i. 510; South on the antiphlogistic treatment in compound fracture, i. 510; South on the exhibition of opium in compound fractures, i. 510; South on bread and water poultices in compound fractures, i. 510; South on the enlargement of the wound, and on sawing off the projecting portion of bone, i. 510; South on the removal of splinters, i. 510; South on the formation and treatment of abscesses during the progress of compound fractures, i. 511; South on the treatment of wounded vessels in compound fractures, i. 511; South on mortification in compound fracture, and its treatment, local and general, i. 511; measures proposed to keep the limb at rest, i. 512; Larrey and Seutin on the treatment for compound fracture, i. 512; Amesbury's fracture-apparatus, i. 512; choice of position in compound fracture, i. 513; setting the fracture, i. 513; Astley Cooper on dressing the wound in compound fracture, i. 514; local treatment of the injured limb, i. 514; after-treatment, i. 515; John Hunter on the treatment of compound fracture, i. 515; Astley Cooper on the union of compound fractures, i. 515; summary of Miescher's experiments to ascertain the processes under which suppurating fractures are united, i. 516; conditions under which amputation may be necessary in fractures, i. 517; Astley Cooper and Abernethy on the question of immediate amputation, i. 518; South on the principal points to be considered in determining on the necessity for immediate amputation, i. 519; of the nature and extent of the injury, i. 519; the condition of the patient, and his capability to bear the second severe shock of the operation, i. 520; the immediate and remote consequences of compound fracture, i. 521; sympathetic, symptomatic, or irritative fever, i. 521; Abernethy and John Hunter on symptomatic fever, i. 521; the fever almost invariably subsides as suppuration is established, i. 521; occurrence of secondary constitutional or nervous symptoms, i. 522; amputation must not be performed while the symptomatic fever continues, i. 522; John Hunter on hectic fever, i. 522; Hunter on the removal of the injured limb while the patient is hectic, i. 522; of the advantages hoped for by the immediate removal of the injured parts, in preference to attempting to save them, i. 523; John Hunter on the slight constitutional irritation after amputation, when union by the first intention takes place, i. 523; South on the objects and occasional results of immediate amputation, i. 523; the suspensory apparatus in the treatment of fractures, i. 523; South on Abernethy's bracket-splint, and the swing box or slings, in the treatment of fractures, i. 523; description of Abernethy's bracket-splint, i. 524; description of the swing-box, i. 524; treatment of the subsequent stiffness of the joints, i. 525; re-breaking of badly-united fractures, i. 525; Oesterlen's observations, i. 525; Bosch, Oesterlen, and Wasserfuhr's apparatus for re-breaking the bone, i. 525; various operations on the callus, i.525; Briesche's case of softening of the callus by the internal use of the Carlsbad waters, i. 526; South on the bending of bones, i. 526; *fracture of the nasal bones*, i. 526; are always consequent on immediate violence, and accompanied by bruising or wound, i. 526; symptoms and diagnosis, i. 526; severe bleeding and symptoms of pressure or concussion of the brain sometimes present, i. 526; compound fracture of the nasal bones, i. 526; treatment of simple fracture, i. 526; treatment when the edges of the fracture are depressed, i. 526; plugging the nostrils useless and injurious, i. 527; treatment of the attendant inflammation, i. 527; of the attendant bleeding, i. 527; of the symptoms of brain affection, i. 527; *fractures of the cheek-bones*, i. 527; of rare occurrence, and mostly accompanied with crushing and wound of the soft parts, i. 527; fracture of the zygoma, i. 527; the brain may be affected by the violence, i. 527; diagnosis and treatment, i. 527; fracture of the alveolar process and its treatment, i. 527; Graefe's case of fracture of the upper jaw, i. 527; South's case of extensive fracture of the bones of the face, i. 528; *fracture of the lower jaw*, i. 528; is of rare occurrence, i. 528; site and direction of the fracture, i. 528; injuries which complicate the fracture, i. 528; displacement of the broken bone, i. 528; South on fracture of the lower jaw, i. 528; diagnosis, i. 528; setting the fracture, i. 529; application of a bandage to keep the fracture reduced, i. 529; treatment of fracture of the neck of the jaw-bone, i. 529; compound fracture of the lower jaw, i. 529; Ruetenich, Kluge, Bush, Hartwig, and Wallner's apparatus for fracture of the lower jaw, i. 529; *fracture of the os hyoides or tongue-bone*, i. 530; is of rare occurrence, and always the result of direct violence, i. 530; symptoms, i. 530; South on fracture of the os hyoides in persons who have been hung, i. 530; treatment, i. 530; *fracture of the cartilages of the larynx*, i. 530; the result of severe violence, i. 530; may cause speedy death by suffocation, i. 530; symptoms, i. 530; operation for the reduction of the fracture, and subsequent treatment, i. 530; *fractures and dislocations of vertebræ*, i. 531; situation of the fracture, i. 531; South on the signs and rarity of occurrence of fracture of the spinous process alone, i. 531; fracture of the body of a vertebra rare, and only produced by great violence, i. 531; always connected with injury of the spinal marrow or its nerves, i. 532; occurrence of paraplegia at the time of the accident, or some time after, i. 532; formation of bed-sores, i. 532; fracture and dislocation of the spine above the third vertebra soon fatal, i. 532; fractures below the origin of the phrenic nerves generally fatal in from three to seven days, i. 532; Phillips' case of fracture of the first vertebra and pivot process of the second, i. 532; Jaeger's opinion that the preparations of fractured spine united by callus only shew that the fracture may be cured, but not the palsy, i. 532; case of vertebral fracture with palsy of the lower limbs and bladder, i. 532; South on the occurrence of fracture of the vertebræ without any great violence, i. 532; South's cases of fractured vertebræ from jumping head-foremost into the water, i. 532; South on the causes of fractured vertebra, and on the injury the spinal cord sustains from the accident, i. 533; the danger in fractured vertebra depends on the injury sustained by the spinal cord, i. 533; Cline's sen. case of fracture of the spine without displacement, i. 534; post-mortem appearances in Phillips' case of fracture of the atlas and pivot of the axis, i. 534; case of fracture of the atlas, axis, and fifth vertebra, without displacement, i. 534; dislocation of one vertebra from another, either partially or completely, without fracture, extremely rare, i. 534; denied by Delpech and Abernethy, i. 534; Astley Cooper considers it of very rare occurrence, i. 534; Boyer infers the impossibility of its occurring, i. 535; the cases mentioned by Boyer, Desault, Chopart, and Rust, i. 535; Lawrence's cases of partial or complete dislocation, i. 535; South's case of separation of the under surface of the

second cervical vertebra from the intervertebral substance without displacement, i. 535; Lawrence's case of complete dislocation of the fourth from the fifth cervical vertebra, i. 535; Schuh's case of partial dislocation, i. 536; Lawrence on the occurrence of dislocation of the vertebræ, specially in the neck, i. 536; period at which death occurs after fracture and displacement of the vertebræ, i. 536; Astley Cooper says fracture with displacement above the fourth cervical vertebra immediately fatal, i. 536; this not always the case, i. 536; formation of a false joint in fracture of the spine, i. 537; instances of partial union by ossification in fractured spine, i. 537; Astley Cooper and Brodie on softening of the spinal cord after a severe blow, i. 537; diagnosis, i. 537; treatment general and local, i. 537; South on the treatment of fracture of the spinous processes, i. 538; South and Brodie on the attempt to set a fracture through the body of a vertebra, i. 538; Hardwicke's case, i. 538; South on the treatment of fractured spine, i. 538; treatment of fractured vertebræ with impression, i. 538; the operation of trepanning the spine performed by Cline jun., Wickham, Attenburrow, Tyrrell, Holscher, Smith, and Rogers, i. 538; Charles Bell, Astley Cooper, and Jaeger's opinions respecting this operation, i. 538, 540, 541; Cline's jun. case of trepanning the spine, i. 539; Cline's jun. clinical observations on the case, i. 539; Abernethy and Brodie on the operation of trepanning the spine, i. 541; objections to the operation, i. 541; South's description of the operation, i. 542; South on the after-treatment, i. 542; Knox's spine-bed, i. 542; *fracture of the pelvic bones*, i. 543; of rare occurrence, and always the result of very great violence, i. 543; *fracture of the sacrum (rump-bone)*, i. 543; diagnosis difficult, when the upper part of the bone is broken, because no displacement, i. 543; reduction of fracture of the lower part of the bone, i. 543; subsequent treatment, i. 543; South mentions a preparation of vertical fracture of the sacrum in the College Museum, i. 543; *fracture of the coccyx* rare, and generally in old persons, i. 543; treatment, i. 543; South on fracture of the coccyx, i. 543; *fracture of the ilium or hip-bone*, i. 544; direction of the fracture, and attendant injury to the soft parts, etc., i. 544; South on fractures of the hip-bone, and their danger from rupture of the bladder, i 544; diagnosis of fracture of the hip, share, or haunch-bone, i. 544; South on the diagnosis of fracture of the hip-bone, i. 544; Houston's case of fracture of the haunch-bone followed by abscess in the perineum and urinary fistulæ, i. 545; subsequent treatment, i. 545; *fracture of the breast-bone (sternum)*, i. 545; of rare occurrence, i. 545; causes and direction, i. 545; consequences of the displacement of the fractured portions, i. 545; diagnosis, i. 545; treatment, i. 545; Charles Bell's objection to laying open the fracture and using the elevator, or removing its edge by the lenticular, in order to raise the depressed portion, i. 546; Dupuytren and Günther's mode of treatment, i. 546; general treatment, i. 546; South on the impropriety of any operation to raise the depressed portion of bone, i. 546; *fracture of the ribs*, i. 546; causes, direction, and consequences, i. 546; case of fractured rib caused by severe cough, i. 546; South's case of wound of the heart caused by a broken rib, i. 546; diagnosis, i. 547; local and general treatment, i. 547; Graefe, Larrey, Seutin, Malgaigne, and Baillie on the local treatment of fractured ribs, i. 547; South on the treatment of fractured ribs, i. 547; *fracture of the cartilages of the ribs*, i. 547; diagnosis, i. 548; setting and treatment, i. 548; *fracture of the shoulder-blade (scapula)*, i. 548; parts liable to be broken, i. 548; South on the causes of fracture of those parts, i. 548; *fracture of the acromion*, i. 548; symptoms and treatment, i. 548; South on the symptoms of fracture of the acromion, i. 548: *fracture of the neck of the scapula*, i. 548; diagnosis, i. 549; South doubts the occurrence of this fracture, i. 549; *fracture of the coracoid process*, i. 549; South's case, i. 549; *fracture of the body of the scapula*, i. 549; symptoms and treatment, i. 549; *fracture of the lower angle of the scapula*, i. 549; treatment, i. 549; South on fracture of the body, spine, and angle of the scapula, i. 549; treatment of compound fracture of the scapula, i. 549; *fracture of the collar-bone (clavicle)*, i. 550; situation and causes of fracture, i. 550; *fracture of the clavicle between its sternal end and the coracoid process*, i. 550; diagnosis, i. 550; transverse and oblique fractures, i. 550; setting the fracture, i. 550; deformity generally the result of this fracture, i. 550; mode of reducing the fracture, i. 551; the bandages and apparatus of Galen, Paré, Petit, Kluge, Richter, Heister, Brasdor, Evers, Brünninghausen, Wilhelm, Eberl, Desault, Boyer, Brefeld, Eichheimer, Koppenstædter, Keckely, Cruveilhier, Laserre, Flammant, Delpech, H. Earle, Amesbury, Richerand, Wattmann, Mayor, Huberthal, and Rénaud, i. 551; objections to the apparatus of Heister, Brasdor, Evers, Brünninghausen, and Wilhelm, i. 551;

the apparatus of Desault and Boyer preferable, i. 551; Dupuytren, Cloquet, Salamon, and Jaeger's practice, i. 552; the preference given to Brefeld's apparatus, i. 552; South on the treatment of fractured clavicle, i. 552; application of the apparatus, i. 552; *fracture of the clavicle between the coracoid process and the scapular end*, i. 553; diagnosis and treatment, i. 553; *fracture of the upper-arm (humerus)*, i. 553; *fracture of the neck of the bone*, i. 553; diagnosis, i. 553; causes, i. 553; South on fracture of the greater tubercle, i. 553; Astley Cooper on fracture at the anatomical neck of the humerus, i. 553; South's cases, i. 554; Astley Cooper and South on fracture of the surgical neck, i. 554; setting and treatment of the fracture, i. 554; Richerand's plan of treatment, i. 554; condemned by South, i. 555; *fracture of the body of the bone*, i. 555; situations in which it may occur, i. 555; diagnosis, i. 555; occasional results, i. 555; setting the fracture, i. 555; treatment, i. 555; South on the treatment of fracture of the humerus, i. 556; Seutin and Dupuytren's plan, i. 556; separation of the condyles in fracture of the lower end of the bone, i. 556; symptoms, diagnosis, and treatment, i. 556; Astley Cooper on the union of these fractures, i. 557; South on fracture of the condyles, i. 557; compound fractures of the humerus, i. 557; South on the treatment of compound fractures of the humerus, i. 557; *fracture of the bones of the fore-arm*, i. 557; *fracture of the radius alone*, i. 557; symptoms and diagnosis, i. 557; symptoms of displacement of the fractured ends, i. 557; Dupuytren and Brodie on fracture of the lower end of the radius, i. 558; South on fracture of the neck of the radius, i. 558; *fracture of the ulna*, i. 559; causes and symptoms, i. 559; *fracture of both bones of the fore-arm*, i. 559; situation, causes, and symptoms, i. 559; setting the fracture, i. 559; treatment, i. 559; setting a fracture of the radius or ulna alone, i. 559; Dupuytren on the treatment of fracture of either bone near the wrist, i. 559; Blandin's treatment, i. 560; South on the treatment of fractures of the fore-arm, i. 560; treatment of compound fracture of the fore-arm, i. 560; *fracture of the olecranon*, i. 560; causes and symptoms, i. 560; mode of union of the fractured ends, i. 560; treatment of the fracture by the apparatus of Böttcher, Wardenburg, Astley Cooper, and Amesbury, i. 560; plan of treatment recommended by Duverney, Sheldon, Desault, Feiler, and Earle, i. 560, 561; description of Feiler and Earle's apparatus, i. 561; South on the treatment of fracture of the olecranon, i. 561; *fracture of the coronoid process of the ulna*, i. 561; first described by Astley Cooper, i. 561; treatment, i. 562; union takes place by ligament, i. 562; Jaeger's case of imperfect fracture of the coronoid process, i. 562; *fractures of the bones of the hand*, i. 562; *fracture of the bones of the wrist*, i. 562; causes, symptoms, treatment, and results, i. 562; *fracture of the bones of the metacarpus*, i. 562; causes, symptoms, and treatment, i. 562; *fracture of the phalanges*, i. 562; treatment, i. 562; *fracture of the femur*, i. 562; *of the neck of the femur*, i. 563; situation and direction, i. 563; causes, i. 563; symptoms of fracture of the neck of the femur, i. 563; Astley Cooper on the distinction between fracture within and without the capsular ligament, i. 564; Earle, Smith, Ekl, and Fricke on some of the signs of this fracture, i. 564; Desault, Delpech, Astley Cooper, Ekl, Fricke, Hahn, Jaeger, and South on the in-locking of the broken ends of the bone, i. 564; Paré, Petit, Louis, Desault, Dessaussoy, and Delpech on the rotation of the foot outwards, i. 564; Guthrie, Syme, Stanley, Dupuytren, Astley Cooper, Mercier, Larrey, and Delpech on inversion of the foot, i. 565; diagnosis, i. 565; separation of the head of the femur from its neck from external violence, i. 565; South's case, i. 565; fracture of the neck of the femur distinguished from severe contusion of the hip-joint, i. 565; from dislocation of the femur outwards and upwards, and outwards and downwards, i. 566; from dislocation upwards and inwards, i. 566; Astley Cooper and Gulliver on interstitial absorption in the neck of the femur, i. 566; opinions of surgeons on the prognosis in fracture of the neck of the femur, i. 566; Astley Cooper admits bony union in fractures external to, but not in fractures internal to, the capsular ligament, i. 566; Boyer and Earle opposed to his views, i. 566; bony union may take place within the capsular ligament, i. 567; causes of the non-union by bone in fracture of the neck of the femur, i. 567; Soemmering and South's preparations of fracture within the capsular ligament united by callus, i. 567; Cruveilhier on the production of callus, i. 567; Swan and Stanley's cases of fracture of the neck of the femur within the capsule united by bone, i. 567; setting the fracture, i. 568; arrangement of the bed in fractures of the lower extremities, i. 568; various apparatus for fixing the broken ends of the bone, i. 568; apparatus of Paré, Sabatier, Guyot, Hildanus, La Faye, Arnaud, Duverney, Hedenus, Théden, Bött-

cher, Bernstein, Larrey, Desault, Van Houte, Volpe, Josse, Meyer, Physick, Houston, Alban, Gressley, Brünninghausen, Boyer, Heyne, Hagedorn, Dzondi, Nicolai, Klein, Gibson, Beck, Schürmayer, Weckert, and Sauter, i. 569, 570; Mursinna, Dupuytren, Richerand, and Astley Cooper on the treatment of these fractures, i. 570; fracture-beds of Earle, Amesbury, Smith, Koppenstædter, and Hager, i. 571; the preference given to Hagedorn's apparatus, i. 571; Dupuytren on the advantages of the double inclined position, i. 571; subsequent treatment, i. 571; Dupuytren on the duration of the treatment, i. 571; *oblique fracture of the femur through the great trochanter*, i. 571; symptoms, i. 572; Astley Cooper's bandage for the treatment of this fracture, i. 572; *fracture of the femur below the great trochanter*, i. 572; seat, causes, and direction, i. 572; signs, i. 572; these fractures always a severe accident, and generally cured with deformity and shortening, i. 573; South on simple and compound fractures of the femur, i. 573; the contentive apparatus with splints and limb in a straight direction, i. 573; South on the treatment of fracture of the femur, i. 573; the apparatus with splints, with the limb bent, and the patient lying on the side or back, i. 574; Pott, C. Bell, and Astley Cooper on the bent position, i. 574; Desault, Brünninghausen, Boyer, Hagedorn, and Sauter on permanent extension, i. 574; Earle's fracture-bed, Granger's apparatus, and Mojsisovic's equilibrium plan, i. 574; application of Seutin's permanent apparatus, i. 575; treatment of transverse fractures of the middle of the femur, i. 575; of the upper and lower thirds, i. 575; of oblique fracture, i. 575; of compound fracture, i. 576; of fracture of the femur in children, i. 576; after-treatment, i. 576; *fracture of the condyles*, i. 576; symptoms and treatment, i. 576; *fracture of patella (knee-cap)*, i. 576; direction, nature, and causes, i. 577; diagnosis, i. 577; union of the fractured portions by a fibrous inter-substance, i. 577; complication of the fracture with severe bruising or wound of the joint, i. 577; Gulliver on the union of fractured patella, i. 577; treatment of transverse fracture, i. 578; application of bandages round the joint, when there is considerable separation of the broken pieces, i. 578; Langenbeck and South on the treatment of fractured patella, i. 578; bandages and apparatus of Bücking, Evers, Mohrenheim, B. Bell, Boyer, A. Cooper, Baillif, and Fest, i. 579; treatment of the attendant inflammation, i. 579; subsequent treatment, i. 579; conquences of the injury, i. 579; John Hunter on the processes which follow after union has taken place, i. 579; South on the means to be adopted for the adaptation of the rectus muscle to the new condition of the patella, i. 579; treatment of longitudinal fracture, i. 580; of splintered and compound fracture, i. 580; South on compound fracture of the patella, i. 580; rupture of the ligament of the patella, i. 580; treatment, i. 580; great care required in the application of the apparatus for transverse fracture, i. 580; *fracture of the bones of the leg*, i. 580; causes, i. 580; *fracture of the tibia*, i. 581; direction, diagnosis and treatment, i. 581; *fracture of the fibula*, i. 581; causes and seat of the fracture, i. 581; symptoms, i. 581; frequently accompanied with dislocation inwards of the tibia, i. 581; symptoms of the dislocation, i. 581; treatment of simple fracture, i. 581; *fracture of both bones of the leg*, i. 582; direction and situation of the fracture, i. 582; diagnosis, i. 582; treatment of simple transverse fracture, i. 582; of oblique fracture, i. 582; Posch and Sauter's apparatus for permanent extension, i. 583; treatment of fracture of the leg near the knee-joint, i. 583; compound fracture and its treatment, i. 583; Braun's apparatus, i. 583; Seutin's permanent apparatus for fracture of the leg, i. 583; South on the treatment of fracture of the bones of the leg, i. 583; *fracture of the bones of the foot*, i. 584; of rare occurrence, i. 584; generally caused by immediate violence, i. 584; *fracture of the os calcis*, i. 585; causes and diagnosis, i. 585; signs, i. 585; if the periosteum be completely torn, great displacement may ensue, i. 585; setting the fracture, i. 585; Lawrence's case of fracture of the os calcis, i. 585; Lisfranc's case, i. 585; South's case of compound fracture of the os calcis, i. 585; South on fracture of the phalanges and on the treatment, i. 586.

Franc's operation for varicocele, ii. 297.

Franco on the application of caustic for the radical cure of hernia, ii. 24; on ligature of the hernial sac for its radical cure, ii. 24; on the operation of dilating the abdominal ring, the hernial sac being unopened, ii. 43.

Franz' case of apparent strangulated thyroid rupture, ii. 88.

Frazer, Dr., recommends the removal of the acromion and glenoid cavity in amputation at the shoulder-joint, ii. 960.

Freer on compression in the treatment of aneurism, ii. 210; case of ligature of the external iliac in the groin, ii. 259; case of operation for artificial anus at the lower end of the colon, ii. 329.

Freitag on ligature of the hernial sac for its radical cure, ii. 24.

Fricke's plan for treating burns with a solution of lunar caustic, i. 112; on compression in orchitis, i. 182; the advantages of compression, i. 184; method of examining the length of the limb during the progress of hip disease, i. 253; explanation of the shortening of the limb incorrect, i. 256; explanation of the lengthening of the limb, i. 257; on the distinction between coxalgy and coxarthrocacy, i. 262; Scott's plan of treatment employed with advantage, i. 264; on the treatment of coxalgy, i. 267; case of the reduction of the consecutive dislocation, i. 268; on the torsion of arteries, i. 308; on the mode of practising torsion, i. 309; on the effects of torsion, i. 311; on the torsion of bony vessels, i. 311; on the treatment of severe wounds of the neck, i. 433; on some of the signs of fracture of the neck of the femur, i. 564; on the inlocking of the ends of the broken bone, i. 564; successful operation for sawing off the ends of the broken bone in false joints, i. 594; on the treatment of buboes, i. 659; on the treatment of caries, i. 686; on the operation of episioraphy, ii. 114; operation for varicocele, ii. 297; on excision of the head of the metatarsus, ii. 985.

Friederich on the proximate cause of tetanus, i. 378.

Fritz on the mercurial treatment in hip disease, i. 267.

Friemann on suture of the urethral fistula, i. 741.

Froriep, von, on the proximate cause of tetanus, i. 378; on the causes of splay-foot, ii. 186; on ligature of the femoral below Poupart's ligament, ii. 262; on the application of caustic in varix, ii. 292.

Frost-bite:—definition of frost-bite, i. 125; South on the parallelism of the effects of great degrees of heat and cold upon the animal body, i. 125; Müller's comparison of the effects of heat and cold on the body, i. 126; Hunter's experiments in freezing rabbits' ears, i. 126; case of a soldier, whose scrotum was frost-bitten, i. 126; cold wet sufficient to induce mortification, if continued sufficiently long to reduce the natural heat of the part below a certain standard, i. 126; Sir Joseph Banks' account of his sufferings, and of Dr. Solander's from exposure to cold, i. 126; Dr. Kellie's case, i. 126; effects of frost-bite on a limb, i. 126; Hunter, Astley Cooper, and Larrey on the effects of frost-bite, i. 127; Green and Solly's cases of frost-bite, i. 127; consequences of too suddenly warming a frozen or benumbed part,—chilblains, or gangrene, i. 129; Astley Cooper and Larrey's observations on this point, i. 130; directions to re-animate a frozen person, i. 130; directions for thawing a frozen limb, i. 130; treatment of a part in which mortification is threatened, from its having been too hastily warmed, i. 130; when mortification has taken place, it must be treated in the usual manner, i. 130; chilblains, i. 130; symptoms and results, i. 130; Hunter mentions another inflammation very like chilblains, i. 131; seat of chilblains, i. 131; treatment, i. 131; South on the mustard liniment in their treatment, i. 131; treatment of ulcerated chilblains, i. 131; of gangrenous chilblains, i. 131; prevention of chilblains, i. 131.

Furuncle. *See* Boil.

Gadermann on the operation for strangulated thyroid rupture, ii. 89.

Gaetani Bey's case of resection of the scapula, and acromial end of the clavicle, ii. 1005.

Gairdner, Dr., on the dangerous symptoms occasionally caused by iodine, ii. 661.

Gale on the use of the ligature for wounded vessels, i. 320; on the dressing of wounds, i. 324; on the application of the interrupted suture, i. 328.

Galen on the removal of the relaxed uvula by cutting, i. 147; on the torsion of arteries, i. 308; on the protraction of the period of incubation of hydrophobia, i. 366; bandage for fractured clavicle, i. 551; on aneurism, ii. 197; on the application of two ligatures in aneurism, and the division of the artery between them, ii. 222; on aneurismal varix, ii. 269.

Galenzowski's modification of the German operation of rhinoplasty, ii. 843.

Galé's experiment with the itch-mite, i. 637.

Gall's case of spina bifida, ii. 465.

Gall-bladder, wounds of, i. 479.

Ganglions, ii. 699.

Gangrene, senile. *See* Mortification. Hospital Gangrene. *See* Mortification.

Garengeot first formed four varieties of whitlow, i. 192; on agnails as a cause of whitlow, i. 195; on the operation of dilating the abdominal ring, the hernial sac being unopened, ii. 43; mode of amputating at the shoulder-joint, ii. 956.

Gastrotomy, ii. 391, 444.

Gatesden's, **John** of, Rosa Anglicana, i. 162.

Gaussil on hydrocele caused by gonorrhea, ii. 498.

Gedding's, Dr., cases in which episioraphy was performed, ii. 114.

Gendrin's account of the steps by which the stagnation of the blood in inflammation is produced, i. 29; on the nature of the cores of boils, i. 132; never found any trace of inflammation in cartilage, ii. 236; case of strictured œsophagus communicating with the trachea, ii. 320; on the physical characters of dropsy of the pericardium, ii. 479; directions for the extirpation of the womb, ii. 828.

Gensoul's modification of the operation for deficient columna narium, ii. 841; case of chiloplasty, to remedy a deformity caused by gangrene, ii. 841; doubts Dupuytren's cases of extirpation of the upper jaw, ii. 994; mode of operating in extirpation of the upper jaw, ii. 995; case of extirpation of the superior maxillary bone, ii. 997.

Gerard on the stanching the bleeding from an intercostal artery, i. 447.

Gerber on the varieties of exudations after inflammation, i. 33; on the microscopical resemblance between the lymph-corpuscles and the exudation-corpuscles, i. 34; account of the formation of pus, and the reproductive organization in suppurative wounds, i. 41; description of ichor, puriform mucus, and serous exudation, i. 44.

Gerdy on dislocation of the upper end of the radius forwards, i. 791; plan of inhealing a plug of skin for the radical cure of rupture, ii. 24; mode of operating, ii. 24.

Gibson, Dr., on the use of raw cotton in the treatment of burns, i. 114; his forceps for amputating the tonsils, i. 146; believes the divisions of whitlow, except the first, to be arbitrary, i. 192; on the treatment of whitlow, i. 195; Perkins' plan tried without advantage, i. 196; performance of Barton's operation for anchylosis, i. 247; on the fatal effects of the stings of bees and wasps, i. 351; apparatus for fracture of the neck of the femur, i. 570; on the formation of a false joint with a fibro-ligamentous capsule, and a lining membrane, i. 588; case of old dislocation of the humerus, in reducing which the axillary artery was ruptured, i. 786.

Gilbert's case of resection of the scapula and clavicle together, ii. 1004.

Gleet. *See* Inflammation of the Urethra.

Glisson on the causes of club-foot, ii. 176.

Gluge on the microscopic characters of pus, i. 35; on the nature of medullary fungus, ii. 719.

Gluteal artery, ligature of, ii. 257.

Gmelin's chemical analysis of the fluid in ranula, ii. 406.

Godefrey's cases of anteversion of the womb reduced by position, ii. 147; case of Cæsarian section in which he sewed up the wound in the womb, ii. 442.

Gonalgia, Inflammation of the Knee-Joint, i. 271; symptoms and progress, i. 271; difference between rheumatic and scrofulous white swelling of the knee-joint, i. 271; post-mortem appearances, i. 272; South and Brodie on the diagnostic symptoms of the diseases of the knee, i. 272; Brodie on ulceration of the cartilages of the knee, i. 273; Rainey on a peculiar degeneration of the cartilage in disease of the knee, i. 273; Brodie on scrofulous disease in the cancellated structure of the bones of the knee, i. 274; progress of caries, i. 274. **White Swelling**, i. 274; application of the term, i. 274; the disease very frequent in Great Britain, but rare in Italy, Vienna, and many other parts of Germany, i. 275; Russell and Gotz on the appearances of white swelling on dissection, i. 275; Nicolai on the symptoms and progress of white swelling, i. 275; Nicolai on the anatomy of white swelling, i. 276; prognosis and treatment, i. 277.

Gonorrhea. *See* Inflammation of the Urethra.

Gonorrheal rheumatism and ophthalmia, i. 217.

Gooch on the arrest of hemorrhage by nature, i. 297; quotes a case of wounded gall-bladder, i. 479; bandage for ruptured tendo Achillis, i. 493; case of spasm of the platysma myoides cured by operation, ii. 156; mode of amputating by the circular incision, ii. 891.

Good, Dr. Mason, mentions two kinds of inflammation of the parotid gland, i. 148; the parotid phlegmon, i. 148; abscess of the parotid gland sometimes of considerable magnitude, i. 148; malignant variety of parotid phlegmon, i. 148; the malignant variety of mumps, i. 149; on the malignant degeneration of parotid phlegmon, i. 149.

Goodlad's objection to the term "hysterical," as applied to certain affections of the joints, i. 250; on the local applications in such affections, i. 250; on ligature of the carotid prior to the extirpation of the parotid, ii. 783.

Goodsir on the mucilaginous glands, i. 212; holds with Key in the deposit from the synovial membrane being the cause of ulceration in cartilage, i. 231; on the scrofulous disease of the cancellated texture of the heads of bone, i. 239.

Gotter's opinions relative to the formation of pus, i. 35.

Gottschalk on the treatment of varix, ii. 290.

Gotz on the appearances of white swelling on dissection, i. 275.

Goulard on the stanching the bleeding from an intercostal artery, i. 447.

Goyraud on retraction of the tendons of the fingers, ii. 193; cases of subcutaneous section for cartilaginous bodies in joints, ii. 710.

Graefe's artery-compressor, i. 299; case of fatal gunshot wound of the intercostal artery, i. 447; on the application of su-

tosis of the medullary membrane, ii. 674; Scarpa's exostosis maligna, ii. 674; Otto and von Walther's osteosteatoma, ii. 674; Müller on enchondron, ii. 674; situation of exostosis, ii. 675; proximate and occasional causes, ii. 675; symptoms, ii. 675; diagnosis, ii. 675; prognosis, ii. 676; treatment, ii. 676; extirpation of the exostosis, ii. 676; *osteosteatoma* and *osteosarcoma*, ii. 677; nature and causes, ii. 677; origin and seat, ii. 677; symptoms, ii. 677; treatment, ii. 678; prognosis, ii. 678; *spina ventosa*, ii. 678; characters, ii. 678; symptoms, ii. 678; Wiseman on spina ventosa, ii. 679; origin and causes, ii. 680; nature of the disease, ii. 680; diagnosis, ii. 680; treatment, ii. 680; *formation of tubercles in bone*, ii. 681; causes, ii. 681; varieties, ii. 681; five stages of encysted tubercles, ii. 681; grey granulations, ii. 681; crude, encysted tubercles, ii. 681; softened tubercles, ii. 682; eliminatory and reparatory processes, ii. 682; tubercular infiltration, ii. 682; grey and purulent infiltration, ii. 682; sequestration of the affected part, ii. 682; diagnosis between purulent tubercular infiltration and caries, ii. 682; treatment ii. 683; *fungus of the dura mater and of the skull-bones*, ii. 683; definition of fungus of the dura mater, ii. 683; symptoms, ii. 683; characters and progress of the disease when the bone is destroyed, ii. 684; appearances after death, ii. 684; diagnosis, ii. 684; views as to the origin and course of the disease, ii. 685; Walther on fungus of the dura mater, ii. 685; varieties of fungus of the dura mater, ii. 686; causes, ii. 687; treatment, ii. 688; by operation, ii. 688; Walther's objections to the operation, ii. 688; mode of operating, ii. 688; Bérard and Orioli's cases treated by operation, ii. 689; *Fatty* or *adipose tumours*, ii. 690; origin, ii. 690; characters, ii. 690; South on fatty tumours, ii. 690; seat and characters of lipoma diffusum, ii. 690; Brodie and South on lipoma diffusum, ii 690; characters of fatty tumours arising between the two plates of the cellular expansion beneath the skin, ii. 691; Müller on the varieties of fatty tumours, ii. 691; size and seat of fatty tumours, ii. 691; Astley Cooper, Copland, Lawrence, and Portalupe's cases of very large fatty tumours, ii. 691; Brodie's case of fatty tumour connected with the spermatic cord within the abdominal ring, ii. 692; causes and seat, ii. 692; removal by operation, ii. 692; Brodie on inflammation of fatty tumours, running on to abscess, ii. 693; Brodie and Astley Cooper's opinion that fatty tumours sometimes take on the malignant degeneration, ii. 693; Brodie's case of fatty tumour partially removed by liq. potassæ, ii. 693; South on the extirpation of fatty tumours, ii. 693; removal of lipomata by operation, ii. 693; after-treatment, ii. 693; use of the seton in lipoma uncertain, ii. 694; South on the removal of the roots of the tumour, and on the after-dressing, ii. 694; *encysted tumours* ii. 694; definition, ii. 694; Hunter and South on cysts forming around foreign substances, ii. 694; varieties of encysted tumours, ii. 695; Maunoir on simple serous cysts of the neck, ii. 695; O'Beirne, Bransby Cooper, Fleury, and T. Blizard's cases, ii. 695; Brodie on simple cysts in the female breast, ii. 696; Astley Cooper on cellular hydatids of the breast, ii. 696; Home and South on atheromatous cysts and their contents, ii. 696; nature of the cyst, ii. 696; Hunter on the internal surface of the cyst, ii. 697; form, characters, and development of encysted tumours, ii. 697; inflammation and ulceration of the cyst, ii. 697; proximate cause of encysted tumours, ii. 697; sebaceous tumour on the head, face, etc., described by Astley Cooper, ii. 697; characters, causes, and structure, ii. 698; Erasmus Wilson and Astley Cooper on sebaceous tumours, ii. 698; Astley Cooper and South on the cause of sebaceous tumours, ii. 698; Dalrymple's case of ossified encysted tumour of the eyelid, ii. 699; *ganglia*, ii. 699; characters, ii. 699; treatment of encysted tumours, 699; by dispersion, ii. 699; removal with the knife, ii. 700; by ligature, ii. 700; opening the cyst, and removing it by suppuration or with caustic, ii. 700; treatment of encysted tumours with roots deeply seated among important parts, ii. 701; of encysted tumours caused by closure of a sebaceous follicle, ii. 701; South on the removal of sebaceous tumours by operation, ii. 701; treatment of ganglions, ii. 701; by operation, ii. 702; by extirpation, ii. 703; this operation condemned by South, ii. 703; *hydatids*, ii. 703; characters, ii. 703; divisions, ii. 703; cysticercus cellulosæ, ii. 703; seat and characters, ii. 703; echinoccus hominis, ii. 704; seat and characters, ii. 704; acephalocyst, ii. 704; seat and characters, ii. 704; South's cases of acephalocysts, ii. 704; causes, ii. 705; consequences, ii. 705; specimens of acephalocysts in the humerus in St. Thomas' museum, ii. 705; treatment, ii. 705; *cartilaginoid bodies in joints*, ii. 705; characters, ii. 706; symptoms, ii. 706; diagnosis between these foreign bodies and arthritis or rheumatism, ii. 707; causes, ii. 707; mode of formation, ii. 707; South on the composition of foreign

bodies in joints, ii. 708; treatment by bandages and by operation, ii. 708 ; treatment preliminary to the operation, ii. 709; diagnosis between benignant and malignant cases, ii. 709 ; mode of operating on the knee-joint, ii. 709 ; South on the mode of operating, ii. 709 ; Schreger's operation on the shoulder-joint, ii. 710 ; the subcutaneous section ii. 710; Goyraud and Syme's cases, ii. 710 ; *sarcomatous tumors*, ii. 710 ; characters, ii. 710 ; South on the two kinds of sarcomatous tumors, ii. 710; Lawrence, M'Murdo, and Astley Cooper's cases of cellular membranous tumors, ii. 711 ; South on enlargement of the prepuce and scrotum, ii. 711 ; Titley, Delpech, Liston, and Imbert de Lonnes' cases, ii. 711 ; form and growth of sarcomatous tumors, ii. 711 ; microscopic characters, ii. 712 ; cause, ii. 712 ; treatment, ii. 712 ; South on their removal by operation, ii. 712 ; *lardaceous tumors*, ii. 712 ; Boyer on wens, ii. 712 ; characters and growth, ii. 713 ; termination in malignant ulceration, ii. 713 ; appearances of the tumor when the parts are dissected prior to softening and degeneration, ii. 713 ; after degeneration has taken place, ii. 714 ; Heyfelder on the varieties founded on microscopic examination, ii. 714; causes, ii. 714 ; treatment by ablation, ii. 714; mode of operating, ii. 715 ; Boyer on the cancerous degeneration of steatoma, ii. 715 ; *medullary fungus*, ii. 715; synonymes ii. 715; characters, ii. 715 ; Young, Travers, Carswell, and Walshe on the genus carcinoma, ii. 716 ; symptoms and situation of medullary fungus, ii. 717 ; medullary fungus of the testicle, ii. 717 ; symptoms and termination, ii. 717 ; symptoms of medullary fungus of bone, ii. 718 ; Astley Cooper on medullary fungus of bone, ii. 718 ; appearances of the parts on dissection, ii. 718 ; chemical examination of the brain-like substance, ii. 719 ; Hecht, Maunoir, and Müller on the chemical constituents of the brain-like substance, ii. 719 ; Krause on the microscopic characters of medullary fungus, ii. 719 ; Gluge on the nature of medullary fungus, ii. 719 ; medullary fungus occasionally encysted, ii. 720; characters of the brain-like substance in medullary fungus of the testicle, ii. 720 ; characters of medullary fungus, ii. 721 ; Allan Burns and von Walther on the difference between fungus hæmatodes and sarcoma medullare, ii. 721 ; Abernethy on fungus hæmatodes, ii. 721 ; Müller on the applicability of the term "medullary fungus" to the different forms of soft cancer, ii. 722; Vogel on the essential element of medullary fungus, ii. 722 ; Bradley, Jaeger, and Vogel on the blood fungus, ii. 722 ; Meckel's opinion that melanosis is the same as medullary fungus, ii. 723 ; this opinion only partially correct, ii. 723 ; diagnosis between medullary fungus and scirrhus, ii. 724 ; Breschet's different kinds of carcinoma, merely different degrees of development of medullary fungus, ii. 725 ; Abernethy's sarcoma tuberculatum considered by Meckel to be medullary fungus, ii. 725 ; this opinion incorrect, ii. 725 ; etiology of medullary fungus, ii. 725 ; diathesis fungosa, ii. 725 ; seat and mode of formation of medullary fungus, ii. 725 ; treatment of the disease almost entirely ineffective, ii. 725 ; early ablation of the part or amputation of the limb affords the only chance of cure, ii. 726 ; the disease generally returns sooner or later, ii. 726 ; *polypi*, ii. 726 ; definition and varieties, ii. 726 ; characters of soft polypi, ii. 726 ; of hard polypi, ii. 726 ; of fleshy polypi, ii. 726 ; of fibrous polypi, ii. 726 ; scirrhous degeneration of polypus, ii. 727 ; symptoms of polypus, ii. 727 ; proximate cause, ii. 727 ; fleshy polypi self-reproducing substances, ii. 728 ; occasional causes, ii. 728 ; prognosis, ii. 728 ; treatment, ii. 728 ; by tearing out, ii. 728 ; by cutting it off, ii. 728 ; by the ligature, ii. 729 ; by the actual cautery, ii. 729 ; *polypus of the nostrils*, ii. 729 ; origin and situation, ii. 730 ; symptoms, ii. 730 ; varieties of nasal polypi, ii. 730 ; malignant nasal polypi, ii. 730 ; benignant nasal polypi, ii. 730 ; causes, ii. 731 ; Schreger on the complication of nasal polypus with teleangiectasy, ii. 731 ; Richerand on the respective origins of benignant and malignant nasal polypi, ii. 731 ; prognosis, ii. 731 ; treatment by local astringents, ii. 732 ; by operation, ii. 732 ; tearing away the polypus, ii. 732 ; examination prior to the operation, ii. 732 ; mode of operating, ii. 732 ; the operation on large polypi, ii. 733 ; operation when the polypus is rooted far back in the nostrils, and hangs down behind the soft palate into the throat, ii. 733 ; treatment of the accompanying bleeding, ii. 733 ; South on plugging the nostrils, ii. 734 ; after-treatment, ii. 734 ; application of the ligature, ii. 735 ; mode of operating, ii. 735 ; after-treatment, ii. 737 ; cutting off the polypus, ii. 737 ; mode of operating ii. 737 ; application of the actual cautery ii. 737 ; *polypus of the throat*, ii. 738 ; seat and symptoms, ii. 738 ; treatment by ligature, ii. 738 ; after-symptoms and treatment, ii. 738 ; polypi of the œsophagus, ii. 738 ; mode of operating, ii. 738 ; *polypus in the maxillary sinus*, ii. 739 ; *inflammation of the mucous membrane of the Highmorian cavity*, ii. 739 ; symptoms,

ii. 739; termination in blenorrhagia, ii. 739; symptoms of polypi, ii. 740; state of the parts in osteosteatoma and osteosarcoma, ii. 740; causes of inflammation, ii. 740; *prognosis of the various diseases of the maxillary sinus*, ii. 740; treatment of the inflammation, ii. 741; when chronic, ii. 741; the operation of opening the sinus, when needed, ii. 741; situation at which it should be performed, ii. 741; through the tooth socket, ii. 742; cases in which it should be practised, ii. 742; South on opening the maxillary sinus, ii. 742; after-treatment, ii. 742; South on the after-treatment, ii. 743; *boring into the maxillary cavity in the fossa canina*, ii. 743; cases requiring the operation, ii. 743; mode of operating. ii. 743; after-treatment, ii. 743; cutting away the polypus, ii. 743; the employment of the ligature and tearing off the polypus, ii. 743; application of caustic, ii. 743; of the actual cautery, ii. 743; *boring into the maxillary cavity below the molar eminence, and above the third or fourth molar tooth*, ii. 744; *through the palate*, ii. 744; *on the cheek*, ii. 744; Weinhold's operations, ii. 744; relative value of these operations, ii. 745; operating on the frontal sinus and after-treatment, ii. 746; Dupuytren on encysted cellulo-fibrous tumor of the antrum, and its treatment, ii. 746; *polypus of the womb and vagina*, ii. 746; situation and characters of polypus of the womb, ii. 747; symptoms and progress of the disease, ii. 747; of polypus of the cervix or os uteri, ii. 748; diagnosis of polypus uteri from pregnancy. ii. 748; of polypus protruded through the os uteri, from eversion of the womb, ii. 748; distinction to be made with difficulty, ii. 749; diagnosis of uterine polypus from fungous growths, ii. 749; causes of uterine polypus, ii. 749; treatment by operation, ii. 750; by the ligature, ii. 750; application of Desault's apparatus, ii. 751; of Nissen's instrument, ii. 752; of Ribke's instrument, ii. 752; after-symptoms and after-treatment, ii. 752; cutting off the polypus, ii. 753; mode of operating, ii. 753; *polypus of the vagina*, ii. 754; causes, symptoms, and treatment, ii. 754; *polypus of the rectum*, ii. 754; situation and characters, 754; treatment, ii. 754; *Cancer*, ii. 754; definition, ii. 755; origin, ii. 755; symptoms of scirrhus, ii. 755; progress of the disease, ii. 755; concealed cancer, ii. 755; ulcerated cancer, ii. 756; condition of the parts in scirrhus, ii. 756; in concealed cancer, ii. 756; microscopic elements of scirrhus, ii. 756; Müller on the four several kinds of carcinoma, ii. 757; Müller on carcinoma simplex and fibrosum, ii. 757; Müller on carcinoma reticulare, ii. 757; Müller on carcinoma alveolare, ii. 757; Müller on carcinoma fasciculatum, ii. 758; Dr. Hodgkin on the development and progress of scirrhus, ii. 758; secondary development of cancerous ulceration, ii. 760; seat of cancer, ii. 760; difference in the progress of cancer in different persons, ii. 761; Alibert on the varieties of cancer, ii. 761; diagnosis of scirrhous tumours, ii. 761; Scarpa on the diagnosis between scrofula and scirrhus, ii. 762; Hodgkin on the diagnosis between scirrhus and medullary fungus, ii. 762; Foy's analysis of scirrhus, ii. 763; *cancer in the skin*, ii. 763; origin and seat, ii. 763; symptoms, ii. 763; occurrence of ulceration, ii. 763; origin of cancer in glands, ii. 764; characters of cancer in mucous membranes, ii. 764; cancer in the bones, ii. 764; characters of cancer in the nerves, ii. 764; other tumours in nerves, and their treatment, ii. 764; Cheselden's cases, ii. 765; Astley Cooper's case of tumour in the popliteal nerve, ii. 765; Liston on tumours of nerves, ii. 765; Langstaff, South, Astley Cooper, Cline, and Mayo on tumours in nerves of stumps, ii. 765; cancer a specific disease, ii. 766; cancerous dyscrasy, ii. 767; predisposing and occasional causes of cancer, ii. 767; Hunter on the disposing causes of cancer, ii. 767; prognosis, ii. 767; Scarpa on the nature of scirrhus, ii. 768; Travers on the occasional inertness of scirrhus during life, ii. 768; Brodie and South's cases, ii. 768; treatment of scirrhus and cancer, ii. 768; Leroy d'Etiolles on the statistics of operations for cancer, ii. 768; treatment for effecting dispersion of the tumour, ii. 769; Young, Recamier, and South on compression of scirrhus, ii. 770; removal of the diseased part with the knife or by escharotics, ii. 770; contra-indications, ii. 770; preliminary treatment, ii. 770; necessary to remove all the diseased parts, ii. 770; destruction of a cancerous part by caustic, ii. 771; mode of applying the caustic, and the resulting symptoms, ii. 771; Canquoin's employment of chloride of zinc as a caustic for cancer, ii. 771; Hellmund's mode of applying Cosme's powder, ii. 771; duration of the treatment, ii. 772; symptoms occasionally produced by the arsenical caustic, ii. 772; internal treatment of cancer, ii. 773; exhibition of narcotics to relieve the pain, ii. 773; *cancer of the lips and cheek*, ii. 773; seat and characters of cancer of the lip, ii. 773; microscopic characters of the disease, ii. 773; malignant but non-cancerous ulceration of the lips, ii. 774; treatment of cancer of the lips by extirpation, ii. 774; contra-indications of the operation, ii. 774; mode of operating when the cancer does not

spread down beyond the red part of the lip, ii. 774; South on the operation in such cases, ii. 774; the operation when the cancer has spread beyond the red edge of the lip, ii. 774; union of the divided parts, even when there has been great loss of substance, ii. 775; the operation of chiloplasty, or making a new lip, ii. 775; various modes of operating for chiloplasty, ii. 775; Dieffenbach and Blasius' operations, ii. 775; treatment of cancer of the lip connected with the bone, ii. 776; by operation, ii. 776; of cancer of the cheek, ii. 776; *cancer of the tongue*, ii. 776; characters, ii. 776; prognosis, ii. 777; treatment, ii. 777; by operation, ii. 777; mode of operating, ii. 777; after-treatment, ii. 778; treatment of fungous growths, ii. 778; ligature of the lingual artery, prior to the amputation of the scirrhous portion of the tongue improper, ii. 778; removal of the tongue by ligature, ii. 778; Mirault's operation for ligature of the tongue, ii. 779; Regnoli's operation for the extirpation of the tongue, ii. 779; Arnott's case of malignant tumour of the tongue in which that organ was removed by ligature, ii. 779; *cancer of the parotid gland*, ii. 780; diseases of the parotid, ii. 780; characters of swelling of the parotid, ii. 780; diagnosis between the several tumours of the parotid, ii. 780; treatment in scirrhus and medullary fungus of the parotid, ii. 781; extirpation of the gland a doubtful remedy, ii. 781; arteries in danger of being wounded during the operation, ii. 781; Allan Burns on extirpation of the parotid, ii. 782; mode of operating for the extirpation of the parotid, ii. 782; Goodlad and Langenbeck on the prior ligature of the carotid, ii. 783; after-treatment, ii. 783; *cancer of the breast*, ii. 783; symptoms, character, and progress, ii. 784; Brodie and South on scirrhus of the breast, ii. 784; characters of scirrhus and cancerous ulceration of the breast, ii. 785; development of cancer of the breast as skin cancer, ii. 785; characters of cancer of the areola, ii. 785; of cancer of the nipple, ii. 785; Astley Cooper on fungous degeneration of the nipple, ii. 786; Astley Cooper on the development of the nipple in the fœtus and its subsequent changes, ii. 786; Brodie on scirrhus of the nipple, ii. 786: symptoms of cancer of the breast, ii. 786; of acute cancer, ii. 786; of chronic cancer, ii 786; Brodie on the puckering in of the skin in mammary cancer, and on its cause, ii. 787; appearance of scirrhus when cut into, ii. 787; diagnosis between scirrhus and chronic inflammation of the lymphatic vessels, or of the breast-gland, ii. 788; symptoms and treatment of the inflammation, ii. 788; symptoms and characters of milk-knots, ii. 789; malignant appearance of milk-knots in old women, ii. 789; Scarpa and South's cases of lacteal swelling, ii. 789; diagnosis between scirrhus and scrofulous tumours of the breast, ii. 790; and herpetic and psoric affections, ii. 790; and encysted tumours, ii. 790; characters of vesicular scirrhus of the breast, or carcinoma mammæ hydatides, ii. 790; this disease a steatomatous degeneration of the gland, ii. 790; Astley Cooper on hydatid swellings of the breast, ii. 791; Astley Cooper on the symptoms and treatment of cellulous hydatids of the breast, ii. 791; Astley Cooper on polypoid hydatids of the breast, ii. 792; Astley Cooper on the lobular hydatids of the breast, ii. 792; Brodie on the serocystic tumours of the female breast, ii. 792; characters of medullary fungus of the breast, ii. 793; of the blood-swelling of the breast, ii. 793; ecchymosis of the breast in girls prior to menstruation, ii. 794; characters of hypertrophy of the female breast, ii. 794; anatomical appearances of the hypertrophied breast, ii. 795; causes, ii. 795; treatment, ii. 795; causes of scirrhus of the breast, ii. 795; prognosis, ii. 796; the question as to propriety of removing a scirrhous breast, ii. 796; opinions of Cline, Home, Astley Cooper, Brodie, and South, ii. 796; Brodie on the circumstances permitting the operation, ii. 797; extirpation of the breast, ii. 797; mode of operating, ii. 797; South on the position of the patient during the operation, ii. 798; South's case of fatal venous hæmorrhage from the extirpation of the breast, ii. 798; South on the after-treatment, ii. 798; amputation of the breast, ii. 798; South's opinion that amputation is not preferable to extirpation, ii. 799; relative value of these operations, ii. 799; requisite to remove all diseased structures, ii. 799; operation for relapse of scirrhus after the removal of the disease, ii. 800; *cancer of the penis*, ii. 800; origin, symptoms, causes, and results, ii. 800; diagnosis. ii. 800; treatment, ii. 800; by operation, ii. 801; amputation of the penis, ii. 801; South on the recurrence of cancer after amputation of the penis, ii. 801; Cline the younger's case, ii. 801; examination of the organ preliminary to the operation, ii. 801; amputation of the penis by the knife, ii. 801; of the glans alone, ii. 801; in the middle of the organ, ii. 801; Schreger's mode of amputating the penis near the pubic bones, ii. 801; Langenbeck's operation, ii. 802; Barthelemy on the means of preventing the retraction of the urethra, ii. 802; occur-

rence of after-hæmorrhage, and its treatment, ii. 802; after-treatment, ii. 802; amputation of the penis by ligature, ii. 802; relative value of the two operations, ii. 802; South on the relative value of the two operations, ii. 803; Lisfranc's operation for the removal of cancer of the corpora cavernosa, ii. 803; *cancer of the testicle*, ii. 803; definition of sarcocele, ii. 804; symptoms and progress of scirrhus of the testicle, ii. 804; characters and appearances of sarcomatous degeneration of the testicle, ii. 804; these diseases occasionally complicated with hydrocele, ii. 804; diagnosis of scirrhous and sarcomatous degenerations of the testicle from other swellings of that organ, ii. 805; from thickening of the cellular tissue of the scrotum, ii. 805; characters and causes of that disease, ii. 805; treatment, ii. 805; by operation, ii. 805; Liston, Key, O'Ferrall, and Bennett's cases of sarcomatous scrotum, ii. 806; diagnosis of sarcocele from simple hydrocele, ii. 809; from cystic swelling of the testicle, ii. 809; characters and appearances of cystic swelling, ii. 809; Astley Cooper on the nature of the cyst in cystic swelling, ii. 809; removal of the disease by operation, ii. 809; hydatids of the testicle, ii. 809; diagnosis of sarcocele from thickening of the tunica albuginea, ii. 809; scirrhus of the tunica albuginea, ii. 809; diagnosis of sarcocele from fungus of the testicle or tunica albuginea, ii. 810; from induration of the testicle, ii. 810; from scrofulous swellings, ii. 810; from syphilitic swellings, ii. 810; from medullary fungus, ii. 810; extirpation of the testicle a doubtful remedy in cancerous degeneration, ii. 811; indications and contra-indications of the operation, ii. 811; Walther and Maunoir on ligature of the spermatic artery in sarcocele, ii. 811; mode of operating, ii. 811; mode of operating for extirpation of the testicle, ii. 812; Aumont's operation, ii. 812; South and Astley Cooper on the retraction of the cord during the operation, ii. 812; degeneration of the spermatic cord, and the operation, ii. 812; South and Cline jun. on ligature of the spermatic cord, ii. 813; dressing the wound, and subsequent treatment after extirpation, ii. 813; treatment of after-hæmorrhage, ii. 813; treatment of undescended testicle, ii. 813; by operation, ii. 813; extirpation of undescended testicle, ii. 813; South on the treatment of undescended testicle, ii. 814; Paget and Arnott's cases of diseased undescended testicle, ii. 814; *cancer of the scrotum*, ii. 815; characters of chimney-sweep's cancer, ii. 815; Pott and Paris on cancer of the scrotum, ii. 815; Earle's case of chimney-sweep's cancer on the wrist, ii. 816; Astley Cooper and Keate's cases of chimney-sweep's cancer on the cheek, ii. 816; Earle and South on the extension of the disease to the neighbouring parts, ii. 816; Travers on the resemblance of the disease to lupus, ii. 816; cause and treatment, ii. 816; South on the cause of the disease, ii. 816; Pott and Earle on the age at which the disease generally occurs, ii. 816; South's case of recurrence of the disease, ii. 816; *cancer of the womb*, ii. 817; origin of the disease, and primary symptoms, ii. 817; indications on vaginal examination, ii. 817; Montgomery on the origin of the disease in the ova Nabothi, ii. 817; progress of the disease, ii. 817; results of the vaginal examination in the advanced state of the disease, ii. 818; Ashwell, Bayle, and Cayol on the pain in cancer uteri, ii. 818; Montgomery and Ashwell's cases of cancer uteri, ii. 818; diagnosis, ii. 818; Simpson on cauliflower excrescence from the os uteri, ii. 818; period of life at which cancer uteri is generally developed, ii. 819; causes, ii. 819; Ashwell on the period of life at which cancer uteri is developed, ii. 819; treatment, ii. 819; by internal and external treatment, ii. 819; can only be palliative in true scirrhus, ii. 820; examination of the parts in cancer uteri by the speculum, ii. 820; mode of introducing the speculum, ii. 820; Simpson on the mode of using the speculum vaginæ, ii. 820; Osiander on the extirpation of the cancerous neck of the womb, ii. 821; modes of operating, ii. 821; Dupuytren's operation, ii. 821; Canella and Hatin's specula vaginæ, ii. 822; von Walther's case of excision of the cervix uteri, preceded by excising the pubic arch, ii. 822; Recamier's operation when the neck of the womb is softened or destroyed, ii. 822; Lisfranc's operation, ii. 822; Colombat's hysterotome, ii. 822; destruction of the degenerated womb by caustic, ii. 822; Mayor's ligature of the neck of the womb, ii. 822; mode of applying caustic potash to destroy the cancerous cervix uteri, ii. 822; cases in which this proceeding is applicable, ii. 823; extirpation of the whole womb, ii. 823; Struve, Gutberlat, and Wenzel on extirpation of the womb, ii. 823; Langenbeck and Land-Wolf's cases of extirpation of the cancerous womb, ii. 823; Recamier's cases of removal of the womb by ligature, ii. 824; Sauter's directions for the operation of extirpation, ii. 824; dressing and after-treatment, ii. 825; von Siebold, Langenbeck, Paletta, Holcher, Blundell, and Banner's cases, ii. 825; Delpech, Dubled, and Recamier on the extirpation of the womb, ii. 826; Roux' cases, ii. 828; the

difficulty and danger of the operation, ii. 828; Gendrin's directions for the operation, ii. 828; Heath's case of excision of the uterus by the abdominal section, ii. 829.

Gruithuisen's opinion relative to the formation of pus, i. 35; microscopic tests for pus and mucus, i. 45; lithotritic instruments, ii. 588.

Guattani's plan of treating aneurism by compression, ii. 209.

Guerin on the causes of congenital dislocation, i. 769; case of congenital dislocation of the lower jaw, i. 772; on the reduction of congenital dislocation of the femur, i. 803; cases of successful reduction, i. 804; mode of proceeding in effecting the reduction, i. 804; on local anodyne applications in strangulated hernia, ii. 32; sub-cutaneous incision of the abdominal ring in strangulated hernia, ii. 43; on the condition of the muscles in curvatures, ii. 150; of the contracted muscles in spinal curvature, ii. 169; on the section of the tendo Achillis in club-foot, ii. 182; on the application of pounded ice to aneurisms, ii. 207.

Gutberlat on extirpation of the womb, ii. 823.

Gueterbock on the chemical and microscopic characters of pus, i. 35; on the composition and chemical analysis of pus, i. 40, 41; discovery of pyine, i. 40; discovery of the difference in size of the pus-globules, i. 41.

Guersant, on the furoncle atonique, i. 133; cases of gangrene of the tonsils, i. 140.

Guillard's case of reduction of a congenital dislocation of the humerus after a lapse of sixteen years, i. 788.

Guillebonneau on the operation for the treatment of lacerated perineum, i. 611; on the application of the sutures, i. 611.

Guillemeau on tying the tonsils, i. 145.

Gulliver on the distinction between the lymph-corpuscles and the exudation-corpuscles, i. 34; on the putrefaction of pus, i. 39; denies the occasional occurrence of pus-globules in healthy blood, i. 41; on thickening and induration of the cellular tissue of the ancles and feet in soldiers, i. 104; on induration and rigidity of the cellular tissue of the ancles and feet in soldiers, without thickening, i. 105; on interstitial absorption in the neck of the femur from external violence, i. 566; on the union of fractured patella, i. 577.

Gunning on immediate amputation in gun-shot wounds, i. 346; case of recurrence of the aneurism, after the ligature of the artery, ii. 225.

Gun-shot wounds, i. 335; definition, i. 335; John Hunter on gun-shot wounds, i. 335; Dupuytren on the effects of gun-shot, i. 336; Dupuytren's case of a person killed by a gun loaded with powder only, i. 336; South's cases of severe injury from small shot, i. 336; pain and hæmorrhage attendant on a gun-shot wound, i. 337; form of the wound, i. 337; shock from the wound, i. 337; subsequent symptoms, i. 337; Guthrie on the pain attending gun-shot wounds, i. 337; Guthrie on the attendant hæmorrhage, i. 337; Guthrie and Hennen on the shock caused by a gun-shot wound, i. 338; Hunter on the character of gun-shot wounds, i. 338; H. Larrey's cases of regular-shaped gun-shot wounds, i. 338; direction of the shot, i. 339; general kinds of injury from shot wounds, i. 339; division of shot wounds into simple and complicated, i. 339; Rust and Busch's explanation of wounds from the wind of the ball, i. 339; Hennen on severe bruising from shot, i. 339; Guthrie on the appearances caused by the passage of a ball, i. 339; Dr. Thompson and Dupuytren on the splitting of the ball by the sharp edge of a bone, i. 339; Guthrie on the resistance offered to the passage of the ball by bone or an elastic body, i. 340; shot wounds generally complicated by foreign bodies in their cavity, i. 340; prognosis, i. 340; indications of treatment, i. 340; circumstances under which the enlargement of the wound may be necessary, i. 340; Hennen on the treatment of wounds by a ball in the fleshy part of the arm, thigh, or buttock, i. 341; general and local treatment, i. 341; occurrence of suppuration, i. 341; of secondary hæmorrhage, i. 341; Guthrie, Samuel Cooper, and Dupuytren on secondary hæmorrhage, i. 341; local and general treatment during suppuration, i. 342; Hennen and Dr. Arthur on the use of the seton to bring away separated pieces of bone, i. 342; Staff-Surgeon Boggie's cases, i. 342; treatment of shot wound complicated with fracture, i. 342; Hennen on the occurrence of necrosis in gun-shot injuries of bones, i. 342; bleeding from the whole surface of the wound in long-continued suppuration, i. 343; the circumstances in gun-shot wounds requiring amputation on the spot, i. 343; Hennen on the nature of the injuries in gun-shot wounds requiring amputation, i. 344; amputation, under the circumstances mentioned, should be performed early, i. 344; Wiseman, Le Dran, and Ranby on immediate amputation, i. 345; Faure on the propriety of delaying the operation, i. 345; Bilguer's objections to amputation altogether, i. 345; Hunter's objections to primary amputation, i. 345; Hennen, Pitcairn, Gunning, and Guthrie on immediate amputation, i. 346; Guthrie's reasons for an early performance of the operation, i. 347; symptoms which may require the performance of amputation at a time more or less posterior to the date of the injury, i. 347.

Günther's treatment of fractured sternum, i. 546; on the condition of the muscles in snake-like scoliosis, ii. 161.

Guthrie on the after-management of ligatures on arteries, i. 306; case in which a ligature remained on the brachial artery for four months after amputation, i. 307; on the pain attending gun-shot wounds, i. 337; on the attendant hæmorrhage i. 337; on the shock caused by a gun-shot wound, i. 338; on the appearances caused by the passage of a ball, i. 339; on the resistance offered to the passage of the ball by bone, or an elastic body, i. 340; on secondary hæmorrhage, i. 341; on immediate amputation, i. 345; reasons for an early performance of the operation, i. 347; on bruising or destruction of the periosteum, not necessarily followed by exfoliation or death of the bone, i. 386; on the difference between the primary and secondary swellings, i. 386; on cold lotions in bruises of the scalp, i. 387; on the existence of pus beneath the dura mater, i. 387; on fracture of the inner table of the skull from the blow of a sword, axe, or other clean-cutting instrument, i. 390; cases of fatal perforation of the orbitar plate of the frontal bone, i. 396; on stertor an uncertain sign of compression, i. 404; on a peculiar whiff or puff from the corner of the mouth a sign of compression, i. 404; on inversion of the foot in fracture of the neck of the femur, i. 565; on the duration of syphilis under the non-mercurial treatment, and on the subsequent occurrence of secondary symptoms, i. 671; on the treatment of vesico-vaginal fistula by compression with a sponge, i. 752; cases of dislocation of the astragalus outwards, i. 810; on the predisposing causes of aneurism, ii. 203; on the relative frequency of aneurism in the sexes, ii. 203; on the return of the pulsation in the aneurism for a short time, after the ligature of the artery, ii. 223; on ligature of the aorta, ii. 255; mode of amputating at the hip-joint, ii. 940; on gun-shot wounds, causing fracture of the humerus beneath and external to the capsular ligament, ii. 960; case of excision of part of the hand, ii. 965; on the excision of joints, ii. 969.

Guyot's apparatus for fracture of the neck of the femur, i. 569.

Haar, van der, on the lengthening of the limb in hip disease, i. 257; on the dislocation of the head of the thigh bone downwards, and inwards in hip disease i. 258; on the treatment of abscesses at the hip, i. 268.

Hachmann on spontaneous inversion of the womb from spasm, ii. 117.

Hacker on the hydriodate of potash in syphilis, i. 670.

Haen's, De, opinions relative to the formation of pus, i. 35; on the lengthening of the limb in hip disease, i. 258.

Hagedorn's apparatus for fracture of the neck of the femur, i. 570; preferred by Chelius, i. 571; on permanent extension in fracture of the femur, i. 574.

Hagen's case of reduction of the consecutive dislocation in hip disease, i. 268.

Hager's fracture-bed, i. 571; on the upper and lower ischiatic ruptures, ii. 87; mode of operating in exarticulation of the forearm at the elbow, ii. 962.

Hahn on the inlocking of the broken ends of the bone in fracture of the neck of the femur, i. 564.

Haighton's experiments on the simultaneous division of both pneumo-gastric nerves, i. 330.

Haire on the after-management of ligatures on arteries, i. 306.

Hall's, Dr. Marshall, operation for prolapsus uteri, ii. 112.

Halpin, Dr., on the reduction of the retroverted womb, ii. 144.

Hammond's case of exarticulation of the astragalus, ii. 946.

Hancock's case of dislocation of the os calcis, i. 813.

Hand, fracture of the bones of, i. 562; dislocation of, i. 793; curvature of, ii. 191; permanent bending of, ii. 192; permanent straightening of, ii. 192; artificial, ii. 848; exarticulation of, at the wrist, ii. 963.

Handyside's, Dr., mode of amputating at the ancle-joint, ii. 945.

Hankel's case of dislocation of the ribs, i. 776.

Hanney on the treatment of fissured nipples, i. 154.

Hard on tying the tonsils, i. 145.

Hardening. *See* Induration.

Harder on the action of the poison of hydrophobia on the system, i. 372; on the stanching the bleeding from a wounded intercostal artery, i. 448.

Hardwicke's case of fracture through the body of a vertebra, i. 538.

Hare-lip, i. 594; nature, situation, and complications, i. 595; South on hare-lip not a complete impediment to sucking, i. 595; causes, i. 595; occasional absence of the olfactory nerves, i. 595; Pigné on the direction and position of natural and acquired hare-lip, i. 595; cure of hare-lip by operation, i. 595; occasional closure of the cleft palate after the operation for hare-lip, i. 595; period at which the operation should be performed, i. 595; removal of projecting bone or teeth prior to the operation, i. 595; Lawrence, Mütter, and South on the period at which the operation should be performed, i. 596; South on the removal of the projecting teeth prior to the operation, i. 596; description of the operation, i. 596; South on the position of the child's head during the operation, i. 597; Lawrence on the use of scissors with knife edges in the operation, i. 597; South prefers the bistoury, i. 597; stanching the bleeding, and application of the sutures or hare-lip pins, i. 597; Dieffenbach, Mayor, Lawrence, and South on the sutures in the operation for hare-lip, i. 598; treatment after the operation, i. 598; South on the rarity of bleeding after the operation, i. 598; South on the time the pins should be left, and on their removal, i. 599; subsequent treatment, i. 599; tearing out of the needles, i. 599; Van Onsenoort's plan to prevent the needles tearing out, i. 599; South on the tearing out of the needles, i. 599; treatment of double hare-lip, i. 599; treatment of cleft in the hard palate, i. 599; Mütter on the advantages of operating early in hare-lip and cleft palate, i. 599; Mütter on the treatment of cleft palate after the operation for hare-lip, i. 599; South and Mütter on the use of obturators in cleft palate, i. 600; *operation for cleft in the hard palate*, i. 600; Mettauer and Mütter's operation of staphyloplasty by granulation, i. 600; description of the operation, i. 600; Mütter's successful operation in a case of loss of substance in the hard palate from chronic mercurial disease, i. 601; *cleft in the soft palate*, i. 602; not unfrequently an original malformation, i. 602; often connected with cleft in the hard palate, and with hare-lip, i. 602; consequences of cleft in the soft palate, i. 602; inutility of artificial palates, i. 602; use of elastic obturators when the cleft cannot be united, i. 602; cure of cleft in the soft palate by staphyloraphy, i. 602; the operation first proposed by Graefe, i. 603; the operation applicable in other diseased states of the soft palate, i. 603; Ebel and Graefe's preparation of the parts for the operation, i. 603; description of the operation, i. 603; Le Monnier's operation of staphyloraphy, i. 603; Colombe's experiments on the dead body, i. 603; artificial means not necessary to keep the mouth open and press down the tongue, i. 604; Graefe, Roux, Ebel, Krimer, Dieffenbach, Bérard, and Alcock on the removal of the edges of the cleft, i. 604; application of the sutures, i. 604; Graefe, Roux, Ebel, Doniges, Warren, Wernecke, Lesenberg, and Krimer's plans for bringing the edges of the cleft together, i. 604, 605; Wernecke, Ebel, and Doniges' instruments for drawing the knots, i. 605; Dieffenbach's mode of uniting the cleft, i. 605; Hruby's palate-holder, i. 605; Schwerdt's cleft needle for the introduction of the thread, i. 605; Berard's mode of passing the needle, i. 605; Smith's lance-shaped notched needle, i. 605; objected to by Mütter, i. 605; Alcock, Hartig, and Liston's mode of operating, i. 605; Fergusson's new mode of staphyloraphy, i. 605; when the cleft is very large, incisions on each side of it necessary to relieve the tension, when the operation has been performed, i. 606; Bonfils, Roux, Krimer, Dieffenbach, and Warren's operations, i. 606; treatment after the operation, i. 606; Graefe and Dieffenbach on the after-treatment, i. 607; Roux and Bérard's fatal cases from pneumonia, i. 607; treatment of the cleft if union do not take place, or is only partial, i. 607; Dieffenbach's mode of closing the fissure which sometimes remains after the operation, i. 607; the alleged disadvantages of the lead wire introduced by Dieffenbach, not real, i. 607; subsequent education of the voice, i. 607.

Harless' case of reduction of the consecutive dislocation in hip-disease, i. 268.

Harris' operation for enlargement of the tongue, ii. 651.

Hartig's mode of operating in staphyloraphy, i. 605.

Hartwig's apparatus for fracture of the lower jaw, i. 529.

Hasse on the formation of new vessels, i. 292.

Hasselberg on hydriodate of potash in syphilis, i. 669.

Hatin's speculum vaginæ, ii. 822.

Havers, Clopton, on the mucilaginous glands, i. 212.

Haymann's operation for resection of the scapula, ii. 1002.

Hayward's, Dr., employment of ether by inhalation prior to the performance of important surgical operations, ii. 1007.

Head, Wounds of the:—should be considered in a double point of view, as regards the direct and consecutive affections, i. 383; general treatment of simple injuries, i. 383; wounds of the aponeurosis of the skull and pericranium, complicated with an elastic, reddish swelling, and followed by erysipelas, i. 383; treatment, i. 383; flap-wounds of the coverings of the skull, i. 383; South on the non-necessity for sutures in wounds of the scalp, i. 384; bruises of the coverings of the skull, i. 384; South on bruises of the coverings of the skull, followed by collections of fluid blood, i. 384; symptoms of

bruises of the skull, i. 384; post-mortem appearances, i. 384; Pott on the puffy, circumscribed, indolent tumor of the scalp, indicative of suppuration between the dura mater and the skull, i. 385; Dease refers the principal cause of disease in these injuries, not to inflammation and suppuration of the dura mater, but to injury of the pia mater and brain, i. 385; Dease on the cases in which the cranium is laid bare, contused, or its tables simply divided, i. 386; Guthrie on bruising or destruction of the periosteum, not necessarily followed by exfoliation or death of the bone, i. 386; Guthrie on the difference between the primary and secondary swellings, i. 386; treatment of bruises of the skull, i. 386; treatment of the subsequent inflammation, and compression of the brain from suppuration on its surface, &c., i. 387; South on poultices in bruises of the scalp, i. 387; Guthrie and Hennen on cold lotions in that injury, i. 387; South on the treatment when inflammation of the dura mater has set in, i. 387; Dease's rules for the application of the trephine, i. 387; Guthrie on the existence of pus beneath the dura mater, i. 387; Dease on puncturing the dura mater, when pus is not found between it and the skull, i. 387; cuts of the skull, i. 388; Hennen and Thomson on sabre-wounds of the head, i. 388; superficial wounds caused by a sharp instrument penetrating to the diploe, or through the inner table of the skull, i, 388; similar wounds made with a blunt instrument, and accompanied with splintering of the bone, i. 388; Hennen's cases of sabre-cuts of the head, i. 388; Thomson on sabre-cuts of the head and neck, and the infrequency of hernia cerebri, i. 389.—*Fractures of the Skull*, i. 389; clefts or fissures, i. 389; counter-clefts and counter-fractures, i. 389; Pott on the symptoms accompanying fracture of the skull, not depending on the injury to the bone, but from injury to the brain, or some of the parts contained in the cranium, i. 389; indications of fracture of the skull, i. 389; South on bleeding at the ears a sign of fracture at the base of the cranium, i. 390; immediate results of fracture of the skull, i. 390; Guthrie on fracture of the inner table of the skull from the blow of a sword, axe, or other clean cutting instrument, i. 390; the danger of clefts and fractures of the skull much exaggerated, i. 391; South on the non-necessity for the trephine in general, i. 391; fracture of the skull with impression, i. 391; indentation of the skull, i. 391; effects of indentation of the skull, i. 391; Green's case of indentation of the skull in a child, i. 391; Astley Cooper and South on fracture of the frontal sinuses, i. 392; Astley Cooper and South on apparent fracture and depression of the skull, i. 392; fractures with impression of the skull require immediate trepanning, i. 392; South, Astley Cooper, and Abernethy on the treatment of simple fracture with depression without the trephine, i. 392; Dease's objection to the use of the trepan in simple fractures, i. 393; in simple depressed fracture, with decided symptoms of pressure on the brain, trepanning should be performed, i. 394; Astley Cooper on the necessity for raising or removing the depressed bone in compound fracture, i. 394; Hennen does not coincide in this opinion, and gives cases of musket-shot wound of the skull in illustration, i. 394; separation of the sutures of the skull by violence, i. 394; the severity of the violence causing injury of the skull an important point in determining the danger, i. 394; Hennen on gun-shot wounds of the skull, and their effects, i. 394; Dr. Cunningham's case of compound fracture of the skull, and lodgment of the breech of a pistol within the cranium, i. 395; Astley Cooper's case of the lodgment of a ball in the frontal sinuses, i. 395; Dr. O'Callaghan's case of the lodgment of a foreign body in the frontal sinuses, i. 395; injuries of the brain and its membranes, i. 396; Hennen on perforations of the skull by bayonet-thrusts, i. 396; Astley Cooper's case of fatal perforation of the orbitar plate of the frontal bone, i. 396; Guthrie's cases of fatal perforation of the orbitar plate of the frontal bone, i. 396; South on the importance of caution in the prognosis of wounds of the orbit, i. 397; Dr. Congreve Selwyn's case of recovery from wound of the brain, i. 397; the first indication in injuries of the brain and its membranes, is to search for and withdraw all foreign bodies, i. 398; Astley Cooper, Brodie, Hennen, Larrey, and Percy on the removal of foreign bodies in injuries of the brain, i. 398; Lawrence's case of pistol-shot wound of the brain, i. 398; Cline jun. and Astley Cooper on puncturing the brain in wounds of the dura mater, i. 399; treatment during suppuration, i. 399; treatment of abscess of the brain, i. 399; South on the propriety of opening abscess of the brain, i. 399; La Peyronie's case of abscess of the dura mater, i. 399; Dupuytren's case of abscess of the brain, successfully opened, i. 399; consequences of foreign bodies remaining in the brain, i. 399; South on the consequences of foreign bodies remaining in the brain, i. 399; Langlet's case of a ball remaining in the brain for eighteen

months, i. 400; inflammation of the brain and its membranes, i. 400; causes, i. 400; symptoms and post-mortem appearances of acute inflammation of the dura mater, i. 400; symptoms of chronic inflammation of the dura mater, i. 400; Astley Cooper's case of chronic inflammation of the dura mater, i. 400; South on chronic inflammation of the dura mater, i. 401; symptoms and post-mortem appearances of acute and chronic inflammation of the brain, i. 401; abscess of the brain, i. 401; Green's case of sympathetic abscess of the brain, with irritation and suppuration of the dura mater, i. 401; Prochaska's case, i. 402; prognosis and treatment of inflammation of the brain, i. 403; South on mercury in the treatment of inflammation of the brain, i. 403; if the symptoms continue, trepanning must be had recourse to, i. 403; if symptoms of suppuration occur, prognosis very unsatisfactory, i. 403; trepanning advisable under such circumstances, i. 404; great care and watchfulness requisite in every injury of the head, to guard against the insidious inflammation of the brain which occurs at a later period, i. 404; inflammation of the brain sometimes simulated by the effects of impurities in the bowels, i. 404.—*Pressure on the Brain*, i. 404; causes, i. 404, 405; symptoms, i. 404; Guthrie on stertor an uncertain sign of compression, i. 404; Guthrie on a peculiar whiff or puff from the corner of the mouth a sign of compression, i. 404; prognosis i. 405; treatment, i. 405; South on mercury in compression, i. 405; removal of extravasated blood either by absorption or trepanning, i. 405; signs indicative of the propriety of trepanning, i. 405; removal of the extravasation after the performance of the operation, i. 406; South on the removal of the extravasated blood after the operation, i. 406; South, Pott, and Brodie on puncturing the dura mater, when the extravasation lies beneath it, i. 406; Pott on the extravasation between the meninges or on the surface of the brain, i. 406; Chevalier and Ogle's cases, i. 407; Hunter, Astley Cooper, Abernethy, and Lawrence on puncturing the dura mater to evacuate the effused blood, i. 407; South on the operation of trepanning to remove effused blood, i. 408.—*Concussion of the Brain*, i. 408; symptoms, i. 408; Astley Cooper and South on the state of the pulse in concussion, i. 409; Astley Cooper and Larrey's cases of loss of memory, &c., after concussion, i. 409; Hennen on the loss of certain faculties from concussion, i. 409; Astley Cooper on the condition of the alimentary canal and bladder during concussion, i. 409; the diagnosis of concussion from compression, i. 409; concussion and compression may occur together, i. 410; difficult to distinguish between drunkenness and concussion or compression, i. 410; in drunkards delirium tremens may succeed concussion, i. 410; inflammation of the brain may be connected with concussion, i. 410; primary and consecutive changes in the brain from concussion, i. 410; Dupuytren distinguishes between commotion and contusion of the brain, i. 410; Walther and Astley Cooper on the symptoms of laceration of the brain, i. 410; Astley Cooper on the condition of the brain in moderate concussion, i. 410; causes of concussion, i. 411; Astley Cooper on the causes of concussion, i. 411; Schmucker's case of concussion, i. 411; prognosis, i. 411; treatment, i. 411; South on the treatment of concussion, i. 411; Astley Cooper's case of enormous blood-letting in concussion, i. 412; after-treatment, i. 412.—*Trepanning in Injuries of the Head*, i. 412; opinions of surgeons differ as to the application and necessity of the trepan, i. 412; Dease, Desault, Richter, Abernethy, Astley Cooper, Brodie, Langenbeck, and Walther only employ it when secondary symptoms of irritation and pressure require it, i. 412; Petit, Quesnay, Pott, Sabatier, Louvrier, Mursinna, Zang, and Schindler employ the trepan more generally, i. 413; reasons by Dease and others for the infrequent use of the trepan, i. 413; South on the infrequency of fungus of the brain after trephining, i. 413; reasons by Petit and others for a more general use of the trephine, i. 413; non-necessity for the use of the trephine in the majority of cases, i. 414; the trepan should only be employed for the removal of decidedly dangerous conditions in injuries of the skull, i. 414; indications for trepanning, i. 415; South on trepanning in caries and necrosis, i. 415; Dr. Wells' case of epilepsy consequent on fissure of the skull, relieved by the trephine, i. 416; Green's case of cataleptic fits after fracture of the parietal bone, i. 416; Green's case of insanity following a blow over the longitudinal sinus, i. 417; Astley Cooper's case of suspended intellect, the consequence of an injury to the head, cured by the application of the trephine, i. 418; parts of the skull where the trepan may be applied, i. 418; the operation of trepanning, i. 419; directions for using the arch-trepan, i. 419; South on the distinction between the trepan and the trephine, i. 420; operating with the trephine, i. 420; South on the operation of trephining, i. 420; trepanning on the frontal sinuses, i. 422; South on trepanning on the frontal sinuses, i. 422; removal of the piece of bone, i. 422; South on the removal of the depressed and detached bone, and of any points from the edge of the fracture, i. 422; application of several crowns, i. 422; South on the infrequency of the necessity to apply the trephine more than once, i. 422; completion of the operation after the employment of the trepan, i. 423; South on bleeding from the middle meningeal artery or from a sinus, i. 423; after-treatment, i. 423; South on the after-treatment, i. 424; general treatment, i. 424; dressing the wound, i. 424; the process adopted by nature in filling up the opening in the skull, i. 424; unhealthy suppuration, i. 425; fungus of the dura mater, i. 425; fungus of the brain, i. 425; treatment, i. 425; protection of the part operated on by pads of leather, or of metal lined with wood, i. 425; Larrey on the subsequent effects of the closure of the opening in the skull, i. 425; various bandages for injuries of the head, i. 425; abscesses in the liver consequent on injuries of the head, i. 426; Hennen on sympathetic affections of the liver, stomach, lungs, and heart in injuries of the head, i. 426; Hennen on priapism in injuries of the head, i. 426; Hennen on loss of the generative faculty from injuries of the back of the head, i. 426; causes of abscesses of the liver after injuries of the head, i. 426; Hennen on the sympathy between the brain and the liver, i. 426; signs and termination of abscesses of the liver, i. 427; treatment, i. 427.

Heart, wounds of, i. 454; displacement of, ii. 96; actual protrusion of, ii. 96.

Heath's case of excision of the uterus by the abdominal section, ii. 829.

Hecht on the chemical constituents of the brain-like substance in medullary fungus, ii. 719.

Hedenus' apparatus for fracture of the neck of the femur, i. 569.

Heine's case of reduction of the consecutive dislocation in hip-disease, i. 268; artificial leg, ii. 846.

Heister's artery-compressor, i. 299; bandage for fractured clavicle, i. 551; objected to, i. 551.

Held on the division of the peronei muscles in splay-foot, ii. 187.

Hellmund's mode of applying Cosme's powder, as a caustic in the treatment of cancer, ii. 771.

Henle's opinion that the exciting cause of inflammation operates through the nervous system, i. 25; discovery of fatty vesicles in the serum of pus, i. 40; on the continuity of synovial membrane over the cartilage of joints, i. 212; on the fibrous structure of articular cartilage, i. 224; on the non-vascularity of cartilage, i. 224; explains the absorption of cartilage from want of nutriment, i. 234; on the formation of new vessels, i. 292.

Hennen, Dr., on the after-management of the ligature on arteries, i. 306; on the shock caused by a gun-shot wound, i. 338; on severe bruising by shot, i. 339; on the treatment of wounds by a ball in the fleshy part of the arm, thigh, or buttock, i. 341; on the use of the seton to bring away separated pieces of bone, i. 342; on the occurrence of necrosis in gun-shot injuries of bones, i. 342; on the nature of the injuries in gun-shot wounds requiring amputation, i. 344; on immediate amputation, i. 345; on the fatal character of tetanus, i. 380; on cold lotions in bruises of the scalp, i. 387; on sabre wounds of the head, i. 388; cases of sabre cuts of the head, i. 388; does not agree with Astley Cooper that the trephine should be used in all cases of compound fracture of the skull, and gives cases of musket-shot fracture in illustration, i. 394; on gun-shot wounds of the skull, and their effects, i. 394; on perforation of the skull by bayonet-thrusts, i. 396; on the removal of foreign bodies in injuries of the brain, i. 398; on the loss of certain faculties from concussion, i. 409; on sympathetic affections of the liver, stomach, lungs, and heart in injuries of the head, i. 426; on priapism in injuries of the head, i. 426; on the loss of the generative faculty in injuries of the back of the head, i. 426; on the sympathy between the brain and the liver, i. 426; on gun-shot wounds in the neighbourhood of, penetrating the orbit, i. 429; on emphysema in wounds of the windpipe, i. 432; case of wound of the larynx and œsophagus, i. 437: case of severe nervous symptoms following gun-shot wound of the throat, i. 437; on the course taken by balls in wounds of the chest, i. 440; on the prognosis of wounds of the chest, i. 444; on the occurrence of primary and secondary hæmorrhage in incised or punctured wounds of the chest, i. 446; on the immediate treatment of penetrating wounds of the lungs, i. 450; on emphysema, i. 451; case of secondary emphysema, i. 451; on the healing of wounded lung, i. 452; on the protrusion of a portion of lung, i. 453; case of foreign body in the heart, i. 455; case of wound of the pericardium, i. 456; on the escape of the intestines from injury in penetrating wounds of the abdomen, i. 457; on the treatment of penetrating wounds of the abdomen, i. 460; on the use of the suture in wounded intestine, i. 467; on effusion into the cavity of the abdomen in cases of penetrating wounds, i. 472; case of musket-shot wound of the abdomen, the ball passing afterwards *per anum*, i. 474; case of ball wound of the pelvis, involving the bladder, i. 481; on the duration of syphilis under the non-mercurial treatment, and on the subsequent occurrence of secondary symptoms, i. 671.

Hernandez' experiments on the identity of syphilis and gonorrhœa, i. 162, 164.

Hernia:—definition, ii. 1; divisions, ii. 1; *ruptures of the belly*, ii. 1; situation, ii. 1; varieties of ruptures, ii. 2; South on certain forms of ruptures, ii. 2; parts forming the rupture, ii. 2; presence of the hernial sac, ii. 2; cases in which it is absent, ii. 2; South on the presence of the sac in vesical and cœcal herniæ, ii. 2; Taramelli's case of hernia of the vermiform appendix, ii. 3; sub-divisions of the sac, ii. 3; its coverings, ii. 3; changes which take place in the hernial sac, and their causes, ii. 3; case of ossification of the sac, ii. 3; South on the causes of stricture in the body of the sac, ii. 3; South on the hour-glass contraction of the hernial sac, ii. 4; size of ruptures, ii. 4; several ruptures often occur in the same person, ii. 4; double hernial sac very rare, ii. 4; Bransby Cooper, Lawrence, and Astley Cooper on the double hernial sac, ii. 4; Morgan's case of a pouch formed at the mouth of the tunica vaginalis, ii. 4; vertical division of a hernial sac into two, ii. 5; South on the occasional rupture of one side of the sac in femoral hernia, ii. 5; reducible and irreducible ruptures, ii. 5; congenital or acquired ruptures, ii. 5; causes of ruptures, ii. 5; ruptures more frequent in men than women, ii. 6; Lawrence and Cloquet on the statistics of ruptures, ii. 6, 8; symptoms of a reducible abdominal rupture, ii. 8; diagnosis, ii. 8; South on the difficulty of distinguishing between intestinal and omental rupture, ii. 8; symptoms of intestinal rupture, ii. 8; South on the gurgling noise in the rupture, ii. 8; symptoms of omental rupture, ii. 9; of vesical rupture, ii. 9; of other ruptures, ii. 9; ruptures always important diseases, ii. 9; formation of adhesions in the sac, ii. 9; condition of the intestine in the sac, ii. 9; of the omentum, ii. 9; South on the thickening of the intestine in the sac, ii. 10; causes of strangulation, ii. 10; seat of strangulation, ii. 10; signs determining the seat of the strangulation, ii. 10; Malgaigne and Diday on the seat of strangulation, ii. 11; distinction between incarceration and strangulation, ii. 11; Scarpa, Lawrence, Travers, Boyer, von Walther, Jaeger, Langenbeck, Wilhelm, Blasius, A. Cooper, Rust, Sinogovitz, and Seiler on the nature of strangulation, ii. 11; South on incarceration and strangulation, ii. 12; symptoms of acute strangulation, ii. 12; South on costiveness as a symptom of strangulation, ii. 13; South and Luke on the dilatation of a strangulated rupture on coughing, ii. 13; Astley Cooper on the complication of strangulated hernia by the presence of an irreducible rupture, ii. 13; symptoms of strangulation with a less degree of inflammation, ii. 13; causes and symptoms of incarceration, ii. 13; spasmodic incarceration, ii. 13; symptoms of gangrene of the hernia, ii. 14; strangulation of the omentum, ii. 14; may terminate in suppuration or gangrene, ii. 14; Key on the propriety of active general and local depletion in strangulated omental hernia, prior to the operation, ii. 14; treatment of ruptures, ii. 14; of reducible ruptures, ii. 14; reduction of the rupture, ii. 15; South on the application of the taxis, ii. 15; South on the danger attending violence in the application of the taxis, ii. 15; South, Le Dran, De la Faye, Arnaud, Louis, Richter, Scarpa, Sabatier, Dupuytren, Sanson, Lawrence, Key, and Sir Charles Bell on the reduction *en masse*, ii. 15; Green and Callaway's case of reduction *en masse*, ii. 16; Bransby Cooper's case, ii. 17; Luke on reduction *en masse*, ii. 17; Cloquet's explanation of the manner in which this accident takes place, ii. 17; Luke on the signs indicative of the reduction *en masse*, ii. 18; Dupuytren and Luke on the operation required after the reduction *en masse* has occurred, ii. 19; re-descent of a reduced rupture prevented by appropriate bandages, ii. 20; trusses, ii. 21; application of the truss, ii. 21; a truss with a hollow pad required in adherent rupture, ii. 22; a suspender to be used for large, irreducible ruptures, ii. 22; effects from wearing the truss, ii. 22; Cloquet on the spontaneous return of the hernial sac into the abdomen, ii. 22; radical cure of reducible ruptures, ii. 23; five modes of attempting it, ii. 23; Hildanus, Blegny, Winslow, Richter, Langenbeck, Boyer, Ravin, and Beaumont on the use of increased pressure, and the supine posture for that purpose, ii. 23; Jalade Lafond's pad with a reservoir for caustic, ii. 23; Paulus Ægineta, Avicenna, Kern, Franco, and Monro on the application of the actual cautery or caustic for the purpose, ii. 23; ligature and stitching of the hernial sac, ii. 24; practised with various modifications by Berard, Franco, Paré, Nuck, Fabricius ab

Aquapendente, Guy de Chauliac, Le Dran, Freitag, Senff, Schmucker, Theden, Langenbeck, Kern, Petit, Lieutaud. Leblanc, Mauchart, Richter, Dionis, Mery, Arnaud, Schreger, von Graefe, and von Walther, ii. 24; the inhealing a plug of skin, ii. 24; Dzondi, Jameson, and Gerdy's plans, ii. 24; Gerdy's mode of operating, ii. 24; modified by Signoroni and Wützer, ii. 25; Bransby Cooper's case, in which he performed Gerdy's operation, ii. 25; Bonnet, Mayor, and Belmas' operations for the radical cure of hernia, ii. 26; circumstances guiding the decision as to the performance of an operation for the radical cure of hernia, ii. 27; the several operations for the radical cure more or less dangerous, ii. 28; opinions differ as to the value of these operations, ii. 28; Schreger's indications when the operation is admissible, ii. 28; Astley Cooper's case, in which he ineffectually removed the entire hernial sac, ii. 29; Astley Cooper's objections to the ligature of the sac, ii. 29; Petit's case of approaching peritonitis caused by ligature of the sac, ii. 29; Lawrence's objections to operations for the radical cure of hernia, ii. 29; treatment of strangulated rupture, ii. 30; employment of tobacco enemata, ii. 30; South's objections to the use of tobacco enemata, ii. 30; treatment of chronic strangulation, ii. 31; employment of the taxis, ii. 31; symptoms following the reduction, ii. 32; symptoms following failure of the taxis. ii. 32; Ribes and Hey on the application of the taxis, ii. 32; O'Beirne on the introduction of a thick elastic tube through the rectum into the sigmoid flexure of the colon, ii. 32; Ribieri and Guérin on local anodyne applications, ii. 32; Nember, Rennerth, and Preiss on the exhibition of purgatives, &c., ii. 32; Church on the use of tartar emetic, ii. 32; Bell on the muriate of morphia, ii. 32; South's case of mortified intestine from strangulation, ii. 32; the proper time for operating, ii. 34; South on the proper time at which the operation for strangulated hernia should be performed, ii. 34; steps of the operation, ii. 35; preliminary measures, ii. 35; description of the operation, ii. 35; South's objection to lifting up a fold of the skin, and incising it, ii. 35; South on the length of the first incision in scrotal and femoral ruptures, ii. 35; exposure of the sac, ii. 36; South on the division of the coverings, and opening the hernial sac, ii. 36; South on several cases of internal strangulation by bands from the mesentery or diverticula of the ileum, ii. 37; dilatation of the seat of strangulation by cutting, ii. 37; instruments for dividing the strangulating part, ii. 37; South on the division of the stricture, ii. 37; dilatation without cutting, ii. 38; recommended by Thevenin, Leblanc, Lecat, Arnaud, Richter, and Scarpa, ii. 38; South's objections to dilatation without cutting, ii. 38; return of the intestines after the division of the stricture, ii. 38; South on the return of the intestines after the division of the stricture, ii. 38; South on the effusion of fluid after the intestines have been returned, ii. 39; causes which impede the reduction of the intestine, ii. 39; treatment of adhesions, ii. 39; treatment of intestine distended with fæces or air, ii. 39; Lowe, Loëffler, Richerand, Jonas, and von Graefe on puncturing the distended intestine, ii. 39; South on the treatment of adhesion between the omentum or intestine and the sac, ii. 39; South's objections to puncturing or incising the intestine, unless distended with solid matter, ii. 40; treatment of degenerated omentum, ii. 40; its removal by ligature or incision, ii. 40; South and Callaway's cases, ii. 40; Key's advice to unfold the omentum before cutting it off, ii. 41; South's mode of treating the protruded omentum, ii. 41; sloughing of the omentum, ii. 41; Astley Cooper's case, ii. 41; Hewett on the formation by the omentum of a sac enclosing the intestine, ii. 41; South on secondary hæmorrhage from the omentum, ii. 42; Key on abscess in the sac, occasionally reproducing the symptoms of strangulation, ii. 42; the dark violet, or even dusky colour of the intestine should not prevent its reduction, ii. 42; South on this colour, as caused by venous congestion, ii. 42; gangrene of the intestine, and its treatment, ii. 42; treatment of wounded and narrowed intestine, ii. 42; treatment of old irreducible ruptures when strangulated, ii. 42; the operation of dilating the abdominal ring, the hernial sac not being opened, to be rejected in the majority of cases, ii. 43; cases in which it may be adopted, ii. 43; this proceeding adopted by Franco, Paré, Petit, Garengeot, Monro, A. Cooper, Key, and Preiss, ii. 43; advantages of this operation, ii. 43; Guérin's subcutaneous incision of the abdominal ring, ii. 43; Astley Cooper's reasons for recommending the operation of dividing the stricture without opening the sac in large and old ruptures, ii. 43; mode of operating, ii. 43; Lawrence's modification of this operation, ii. 44; Key's views with regard to this operation, ii. 44; Lawrence ascribes the fatal results after the operation, not to the exposure of the parts to the air and light, but to the effects of protracted constric-

tion, ii. 45; South on the consequences of the constriction, and on violence in the application of the taxis, ii. 45; Key and South on the signs indicative of gangrene of the intestine, ii. 45; Key and South's cases of gangrenous intestine, in which a fetid smell was perceptible before the sac was opened, ii. 46; absence of the fetid smell not a certain sign of healthy intestine, ii. 46; Lawrence recommends opening the sac, and dividing the stricture from within, ii. 46; South on the division of the stricture external to the sac, ii. 47; South on the treatment after the operation, ii. 47; Luke's description of the operation for dividing the stricture external to the sac, ii. 47; Luke on the diagnosis of the seat of stricture, ii. 47; Luke on the incision of the sac, or on partial division of its neck in several places, when the stricture is caused by it, ii. 48; treatment after the operation, ii. 48; treatment when the symptoms of strangulation persist after the operation, ii. 49; Key and South on suppuration of the sac, ii. 49; South's case of extensive sloughing of the abdominal and lumbar cellular tissue after the operation, ii. 49; treatment of sloughy intestine, ii. 49; formation of an artificial anus, ii. 49; adhesion of the gut to the mouth of the sac when sloughing takes place, ii. 49; Astley Cooper and Key's cases of sloughing of the intestine, after it had been returned into the abdomen, ii. 49; Ramsden's case of fatal contraction and ulceration of the intestine after strangulation, ii. 49; Key and South on the occurrence of gangrene in the intestine some days after the operation in persons of enfeebled constitution, ii. 50; Key on the fatal termination of cases after the operation, when preceded by great depression of powers, i. 51; Astley Cooper's case of tetanus after the operation, i. 51; tabular view of operations for strangulated rupture, ii. 50; *inguinal rupture*, ii. 54; situation and varieties, ii. 54; anatomy of the parts concerned, ii. 54; South's description of the fascia transversalis, ii. 55; *external or oblique inguinal rupture*, ii. 56; situation and direction, ii. 56; *internal or direct inguinal rupture*, ii. 57; situation and direction, ii. 57; diagnosis between these only possible when small and recent, ii. 57; coverings of the external or oblique inguinal rupture, ii. 57; imperfect inguinal rupture, or rupture in the inguinal canal, ii. 57; situation and coverings, ii. 57; South on the coverings of this variety of rupture, ii. 57; coverings of the internal or direct inguinal rupture, ii. 57; comparative frequency of protrusion of the respective viscera, ii. 58; congenital inguinal rupture, ii. 58; causes, ii. 58; distinguished from external inguinal rupture, ii. 58; coverings of congenital inguinal rupture, ii. 59; narrowing of the hernial sac, ii. 59; congenital inguinal hernia called by Astley Cooper encysted hernia of the tunica vaginalis, ii. 59; diagnosis of rupture from hydrocele, ii. 59; South on the difficulty of diagnosis between rupture and hydrocele of the cord, ii. 60; South's cases of hydrocele of the cord mistaken for rupture, ii. 60; complication of rupture with hydrocele, i. 61; Mr. T. Blizard and Cline's jun. cases of hydrocele in front of an inguinal rupture, ii. 61; diagnosis between rupture and varicocele, ii. 61; and inflammatory swelling of the spermatic cord, ii. 61; and the arrest and inflammation of the testicle in the inguinal canal, ii. 62; Key's case of strangulated inguinal rupture, the testicle being at the external ring, ii. 62; diagnosis between inguinal ruptures and fat-ruptures, ii. 62; collections of fat on the surface of the peritoneum, ii. 62; Pelletan on the mechanism of the fat-rupture, when it descends through the inguinal canal, ii. 62; diagnosis between inguinal rupture, and collections of pus passing through the inguinal canal out at the abdominal ring, ii. 63; return of the inguinal rupture, ii. 63; application of the truss, ii. 63; seat of strangulation, ii. 63; the operation for strangulated inguinal rupture, ii. 63; important in old scrotal rupture on the right side, to ascertain whether the cœcum or commencement of the colon be the protruded viscus, ii. 64; direction of the cut in dividing the stricture, ii. 64; South on the direction of the cut in dividing the stricture, ii. 64; *congenital inguinal rupture*, ii. 64; process of the radical cure, ii 65; operation for strangulated congenital inguinal rupture, ii. 65; the operation for inguinal rupture, without opening the sac, ii. 65; external inguinal rupture in women, ii. 65; Nuck and Cloquet on the diverticulum of the peritoneum, ii. 65; Allan Burns on the frequency of congenital rupture in the female, ii. 65; *femoral rupture*, ii. 66; situation and sub-divisions, ii. 66; Logier on oblique femoral rupture, ii. 66; anatomy of femoral rupture, ii. 66; South on the anatomy of femoral rupture, ii. 67; femoral rupture occurs more rarely than inguinal, and more frequently in women than in men, ii. 69; symptoms of femoral rupture, ii. 69; Astley Cooper and Callaway on the seat of femoral rupture, ii. 70; South on the diagnosis of femoral from inguinal rupture in women, ii. 70; Astley Cooper and South on the presence of other tumors in the femoral region likely to be mistaken for femoral rupture, ii. 70; coverings of femoral rupture, ii. 70; parts protruded in femoral rupture, ii. 70; South on the coverings of femoral rupture, ii. 70; Berard's case of femoral rupture, in which the Fallopian tube was protruded, ii. 71; situation of the epigastric and obturator arteries with respect to femoral rupture, ii. 71; of the spermatic cord, ii. 71; application of the taxis, ii. 71; situation and severity of the strangulation in femoral rupture, ii. 72; Key on the seat of strangulation in femoral rupture, ii. 72; the operation for strangulated femoral rupture, ii. 72; direction of the incision, ii. 72; precautions to avoid wounding the epigastric or obturator artery, ii. 73; Hesselbach's modification of the operation, ii. 73; Scarpa and Dupuytren's modification, ii. 73; Key on the operation for femoral rupture, ii. 74; after-treatment, ii. 74; *external femoral rupture,* ii. 74; situation, signs, and coverings, ii. 74; predisposing causes, ii. 74; application of the taxis, ii. 75; Astley Cooper on the varieties of femoral rupture, ii. 75; South's cases of femoral rupture, with two sacs, ii. 75; wounds of the epigastric or obturator artery, ii. 78; Lawrence on the statistics of these wounds, ii. 78; Lawrence's case of fatal hæmorrhage from a wounded branch of the epigastric, ii. 79; Everard Home's case of suppuration of the testicle consecutive to the operation for strangulated scrotal rupture, followed by severe hæmorrhage, ii. 79; *umbilical rupture,* ii. 79; situation and sub-divisions, ii. 79; *congenital umbilical rupture,* ii. 79; symptoms, ii. 79; South on the ligature of the umbilical cord, ii. 79; causes of umbilical rupture, ii. 80; in adults, ii. 80; coverings, ii. 80; strangulation of rare occurrence, ii. 80; Astley Cooper's case; in which the sac was either absorbed or burst, ii. 80; Cline and South's cases of double umbilical rupture, ii. 80; Astley Cooper on the enormous size of umbilical ruptures in women, ii. 80; treatment of congenital umbilical rupture, ii. 80; treatment of umbilical rupture occurring after birth, ii. 81; Rothmund's plan of treatment, ii. 81; Desault, Soemmering, and Brünninghausen's cases of spontaneous cure of umbilical rupture, ii. 82; the operation for strangulated umbilical rupture, ii. 82; Astley Cooper on the danger of sloughing of the integuments in strangulated umbilical rupture, ii. 82; Astley Cooper on suppuration of the omentum in strangulated umbilical rupture, ii. 82; strangulation of umbilical rupture rarely occurs during pregnancy, ii. 82; Astley Cooper, Lawrence, and Clement's cases, ii. 82; radical cure of reducible umbilical rupture by ligature objectionable, ii. 83; opposed by Scarpa, Astley Cooper, Benedict, and South, ii. 83; Desault's fatal case, ii. 83; *ventral rupture,* ii. 84; definition and situation, ii. 84; causes, ii. 84; Cloquet's case of lumbar rupture, ii. 84; South's cases of rupture of the linea alba, ii. 84; Lawrence's case of rupture of the recti abdominis, ii. 84; case of a boy wounded by a boar's tusk, with protrusion of the omentum, colon, and some small intestines, ii. 84; Richter and Siebold's cases of yielding of the abdominal parietes, ii. 85; situation, contents, and coverings of these ruptures, ii. 85; signs and treatment, ii. 85; diagnosis between ventral ruptures and fat-ruptures, ii. 85; stomach ruptures, their symptoms and treatment, ii. 85; treatment of the other ventral ruptures, ii. 85; *ischiatic rupture,* ii. 86; seat and contents, ii. 86; diagnosis, ii. 86; congenital ischiatic rupture, ii. 86; diagnosis from a fatty or encysted swelling, ii. 86; from spina bifida, ii. 86; coverings, ii. 86; reduction, ii. 86; Astley Cooper and Seiler on the operation for strangulated ischiatic rupture, ii. 87; Hager on the upper and lower ischiatic ruptures, ii. 87; Scarpa treats ischiatic rupture as enlarged pudic rupture in women, and enlarged perineal rupture in men, ii. 87; *thyroid rupture,* ii. 87; situation and boundaries, ii. 87; contents, ii. 88; Cloquet and Lawrence on thyroid rupture, ii. 88; Franz' case of apparent strangulated thyroid rupture, ii. 88; diagnosis, ii. 88; treatment, ii. 88; Astley Cooper and Gadermann on the operation for strangulated thyroid rupture, ii. 89; *vaginal rupture,* ii. 89; situation and contents, ii. 89; symptoms, ii. 89; predisposing causes, ii. 89; treatment, ii. 90; *perineal rupture,* ii. 90; situation and contents, ii. 90; of rare occurrence, ii. 90; characters of the rupture, ii. 91; reduction, ii. 91; Astley Cooper's pudendal hernia, the posterior labial rupture of Seiler, ii. 91; *rectal rupture,* ii. 91; causes, signs, and diagnosis, ii. 91; treatment, ii. 92; *phrenic rupture,* ii. 92; different ways in which this occurs, ii. 92; Macaulay and Astley Cooper's cases, depending on malformation of the diaphragm, ii. 92; Leacock's case of fatal phrenic rupture, ii. 92; *mesenteric and mesocolic ruptures,* ii. 93; nature of the injury, ii. 93; disease necessarily fatal, ii. 94; Dupuytren's operation, ii. 94; *strangulation of intestine within the peritoneal cavity* (internal hernia), ii. 94; Astley Cooper on internal strangulation, ii. 94; Lawrence on the symptoms of

internal strangulation, ii. 94; Rokitansky on internal strangulation, ii. 94; *ruptures of the chest*, ii. 95; very rare, ii. 95; nature and causes, ii. 95; Gratelup and Sabatier's cases, ii. 95; symptoms and treatment, ii. 95; *displacement of the heart*, ii. 96; Breschet, O'Bryen, Ramel, and Deschamps' cases, ii. 96; Stokes' case of displacement of the heart from external violence, ii. 96; *actual protrusion of the heart*, ii. 96; Chaussier's cases, ii. 96; *ruptures of the brain*, ii. 97; nature of the disease, ii. 97; South on cerebral rupture, ii. 97; *congenital cerebral rupture*, ii. 98; causes, situation, symptoms, and results, ii. 98; post-mortem appearances in congenital cerebral ruptures, ii. 98; Otto on hydrocephalocele, ii. 98; Penada, Earle, and Baron's cases, ii. 98; the fluid sometimes contained between the brain and its membranes, ii. 99; Meckel and Otto on the causes of cerebral rupture, ii. 99; double congenital cerebral rupture, ii. 99; Billard and Meckel's cases of cure, ii. 99; *accidental cerebral rupture*, ii. 100; Beck and South on accidental cerebral rupture, ii. 100; Jamieson's case, ii. 100; diagnosis of accidental cerebral rupture from the so-called fungus of the dura mater, ii. 101; between congenital cerebral rupture and the blood-swellings of newly-born children, ii. 101; from watery cysts, ii. 101; treatment, ii. 101; by puncture, ii. 102; operations generally fatal, ii. 102; Earle and Adams' cases of hydrocephalocele treated by puncture, ii. 102; danger of the puncture, ii. 102; Pitschaft's cases of suppurating protrusions in children, ii. 102.

Hernia humoralis. *See* Inflammation of the Testicle.

Herpes and its varieties, i. 628.

Hertwig's observations on canine madness, i. 360; experiments show that the saliva is the vehicle of the poison in hydrophobia, i. 364; also show the contagion to be in the blood of the mad beast, i. 364.

Hesselbach's artery-compressor, i. 299; modification of the operation for femoral rupture, ii. 73; on the treatment of hydrocele by caustic, ii. 506; mode of amputating at the shoulder-joint, ii. 957.

Hetling's case of osteo-sarcoma of the jaws, in which he removed part of the upper, and part of the lower, jaw, ii. 1000.

Heurteloup's percuteur, advantages and disadvantages of, ii. 560.

Hevin's case of renal calculus communicating with abscess in the loins, ii. 542.

Hewett on the formation, by the omentum, of a sac inclosing the intestine, ii. 41; on the connexion between the cord or the nerves, and the walls of the sac in spina bifida, ii. 467; on puncturing spina bifida, ii. 468.

Hewson's opinion relative to the formation of pus, i. 35; operation for the excision of the carious head of the femur in hip disease, i. 270; on the use of caustic to destroy the ends of broken bones in false joints, i. 590; case of cure of false joint by caustic potash, i. 591; case of excision of the head of the femur, ii. 979.

Hey on the possibility of infection from secondary syphilis, i. 675; on the cause of the difficulty experienced in reducing dislocations of the thumb from the metacarpal bone, i. 794; on the mode of reducing this dislocation, i. 795; on the application of the taxis in strangulated hernia, ii. 40; on the cause of the difficulty in reducing the bowel in old prolapses of the rectum, ii. 134; operation for prolapse of the rectum, ii. 134; case of effusion of blood into the knee-joint, ii. 457; on the incontinence of urine consequent on lithotomy in women, ii. 622; case of immense tumour of the nose, ii. 851; mode of amputating the thigh with the flap from behind, ii. 909; on amputation just above the ancle, ii. 921; mode of operating in exarticulation of the metatarsal bones, ii. 949.

Heyfelder on the varieties of lardaceous tumours founded on miscrocopic examination, ii. 714; operation for the resection of both upper jaws, ii. 998.

Heyne's apparatus for fracture of the neck of the femur, i. 570.

Higginbotham's treatment of burns by the nitrate of silver, i. 119; on the treatment of whitlow with nitrate of silver, i. 196.

Hildanus' apparatus for fracture of the neck of the femur, i. 569; on increased pressure and the supine posture in the radical cure for hernia, ii. 23.

Hill on the duration of syphilis under the non-mercurial treatment, and on the subsequent occurrence of secondary symptoms, i. 671.

Hip, abscess of, i. 253; curvature of, ii. 172; amputation of the thigh at, ii. 932; excision of, ii. 977.

Hippocrates on congenital dislocation of the hip, i. 769, 802; on the primitive direction of dislocation of the humerus, i. 782.

Hirtz on the physical phenomena of pleuritic effusion, ii. 472.

Hodgkin, Dr., on the development and progress of scirrhus, ii. 758; on the diagnosis between scirrhus and medullary fungus, ii. 762.

Hodgson's cases of arteritis, i. 74; on severe phlebitis, i. 78; on the bursting of aneurisms, ii. 199; on the relative frequency

of aneurism in the sexes, ii. 203; on the relative frequency of aneurism in the arteries, ii. 203; on the application of pounded ice to aneurisms, ii. 207; on compression in the treatment of aneurism, ii. 210; on the effects produced by the ligature on the arterial coats, ii. 219; case of aneurism of the posterior cerebral ii. 240; on the section of the scalenus anticus in the ligature of the subclavian, ii. 242; proposal to tie the innominata, ii. 245; on ligature of the innominata, ii. 246; on spontaneous aneurism of the brachial, ii. 251; on the coagula in varicose veins, ii. 288.
Hœmatocele, ii. 455.
Hœmorrhoids, ii. 300.
Hoere's case of simultaneous collection of blood between the pericranium and skull, and between the dura mater and skull, the latter being fissured, ii. 454.
Hœring's experiments on the injection of bile into the cavity of the peritoneum, i. 479.
Hoffmann's opinion relative to the formation of pus, i. 35; cases of separation of the head of the femur, and its removal by the surgeon in hip disease, i. 258.
Holbrook on the treatment of hydrocele by seton, ii. 505.
Holscher's case of trepanning the spine, i. 538; case of extirpation of the womb, ii. 825.
Home's, Sir E., opinion relative to the formation of pus, i. 35; on the internal use of arsenic and ginger as a cause of gonorrhœa, i. 162; cases of gonorrhœa in the female, in which the use of stimulating injections caused the sides of the vagina to unite together by adhesive inflammation, i. 172; on the application of a ligature above a viper's bite, i. 354; case of the bite of a rattlesnake, i. 356; on the appearances in the lungs 32 years after their having been wounded by a ball, i. 443; case of suppuration of the testicle consecutive to the operation for strangulated scrotal hernia, followed by severe hæmorrhage, ii. 79; on the Hunterian operation, ii. 216; on the non-necessity for the existence of large collateral branches to ensure the success of the Hunterian operation, ii. 217; on acupuncture of aneurism, ii. 228; on the ligature of the saphena vein for varix, ii. 291; on the use of the armed bougie in stricture of the urethra, ii. 366; case of relapse of hydrocele a long while after the operation, ii. 504; case of foreign body the nucleus of a stone, ii. 524; case of retention of urine, and consequent mortification, from the impaction of calculi in the urethra, ii. 630; on atheromatous cysts and their contents, ii. 696; on the question as to the propriety of removing a scirrhous breast, ii. 796.
Hook foot, ii. 189.
Horner's, Dr., recommendation to divide the sphincter ani in lacerated perineum, after union has taken place, i. 612; proposal to draw down the uterus into the vagina in cases of vesico-vaginal fistula, to act as a plug, i. 759.
Horns, ii. 669.
Horse-foot, ii. 188.
Houston's case of fracture of the haunch-bone, followed by abscess in the perineum, and urinary fistula, i. 545; apparatus for fracture of the neck of the femur, i. 569.
Houte's apparatus for fracture of the neck of the femur, i. 569.
Howship's case of distension of the bladder by blood, ii. 417.
Hruby's palate-holder, i. 605.
Huberthal's apparatus for fractured clavicle, i. 551.
Huguier on the period at which syphilis shows itself after birth, i. 673.
Hulse's treatment of false joints, i. 590.
Humbert's case of reduction of the consecutive dislocation in hip disease, i. 268; on the reduction of congenital dislocation of the femur, i. 803.
Humerus, fracture of, i, 553; dislocation of, i. 781.
Hummel on the arrest of hæmorrhage by nature, i. 297.
Hunczorsky's mode of amputating at the hip-joint with the flap-cut with a single flap, ii. 935.
Hunter, John, on inflammation, i. 22; on the susceptibility for inflammation, and the influence of the constitution with respect to its local effects, i. 23; on the cause of pain in inflammation, i. 25; on the causes of inflammation, i. 26, 30; on the attendant redness, i. 26; experiments on the increase of heat in inflammation, i. 27; opinion on the enlargement of the vessels in inflammation, i. 27; on the cause of the extravasation of serum, i. 33; opinions relative to the formation of pus, i. 35; on the cause and results of suppuration, i. 36; on suppurative inflammation, i. 37; on the circumstances which determine an abscess to the surface, i. 38; on the qualities of pus, and the pus-globules, i. 39; on the putrefaction of pus, i. 39; on ulcerative inflammation, i. 49; ulcerative absorption, or absorption with suppuration, i. 50, 51; progressive absorption, i. 51; on inflammation of the mucous membranes, i. 73; of the serous membranes, i. 73; on the occasional termination of inflammation of serous membranes in suppuration, i. 74; on the coagulation of the blood in phlebitis, i. 77; on severe phlebitis, i. 78; on the red

streaks accompanying inflammation of the absorbents, i. 81; on inducing resolution by constitutional means, i. 82; directions respecting the employment of bloodletting, i. 82; on the local means of inducing resolution, i. 83; on fomentations or steams, washes, and poultices, i. 85; on derivation, i. 86; first pointed out the membrane of the fistula. i. 92; description of it, i. 92; opinion that most inflammations which are called erysipelatous, are not such, i. 99; description of erythema symptomaticum, i. 101; description of metastatic erythema symptomaticum, under the name of erysipelatous inflammation, i. 103; on cold in the treatment of burns, i. 113; on the primary treatment of burns, i. 116; on the contraction of the granulations during cicatrization, i. 121; experiments in freezing rabbits' ears, i. 126; on the effects of frost-bite, i. 127; mentions another inflammation very like chilblains, i. 131; on the inflammation that produces carbuncle, i. 135; his observation that there are generally more carbuncles than one not confirmed by South, i. 135; his opinion that carbuncle has some affinity to boils, i. 136; on the period when gonorrhœa first makes its appearance after infection, i. 156; on the primary symptoms of gonorrhœa, i. 156; on the specific extent of the inflammation, i. 156; on the actual seat of the discharge, i. 156; on the small swellings which are noticed externally near the urethra, i. 157; on the size and form of the stream of urine, i. 157; on the occurrence of hæmorrhage in severe gonorrhœa, i. 157; on inflammatory and spasmodic chordee, i. 157; on the extent of local irritation, i. 158; on the extension of the inflammation to the bladder, and the consequent inability of that viscus to retain its contents, i. 158; case of fever preceding gonorrhœa, i. 158; on the extension of the inflammation in the female to the bladder, i. 159; doubts its extension to the ovaries, i. 159; on abscesses complicating gonorrhœa in the female, i. 160; on gonorrhœa from simple causes, i. 161; case of gonorrhœa caused by leucorrhœa in the female, i. 162; on the identity of syphilis and gonorrhœa, i. 163; accounts for the two different effects of the same poison, by the gonorrhœa proceeding from a secreting surface, and the chancre being formed in a non-secreting surface, i. 163; on the sympathetic swellings in gonorrhœa, i. 167; on the duration and spontaneous cure of gonorrhœa, i. 168; on the treatment of the disease, i. 168; on the remedies for chordee, i. 170; on the arrest of hæmorrhage from the urethra, i. 170; on the infectious nature of gleet, i. 173; on balanitis, i. 176; on the period when swelled testicle supervenes, i. 177; swelling of the testicle arises from sympathy, and not from syphilis, i. 177; on gout, as a cause of orchitis, i. 178; on the fungus which projects when a whitlow bursts, i. 192; reasons for the severity of the pain, and the length of time before a whitlow bursts, i. 193; regards whitlow as an example of the ulcerative process having no power over the cuticle, i. 195; on the treatment of whitlow, and its free and early incision, i. 196; on inflammation of the joints, i. 206; on the ulcerative absorption of cartilage, i. 228; on anchylosis, i. 241; on the inflammatory and scrofulous diseases of joints causing anchylosis, i. 242; on soft anchylosis from granulations, i. 242; on bony anchylosis, i. 242; case of soft anchylosis from the extension of inflammation from the surrounding parts to the joint, i. 246; on the shortening and lengthening of the diseased limb in hip disease, i. 255; on the three kinds of union of divided parts—quick union, by adhesion, and by granulation, i. 288; description of quick union, i. 288; objected to by Dr. John Thomson, i. 288; on the adhesive inflammation, in connexion with wounds, i. 290; on the formation of new vessels, i. 292; on suppuration and granulation as leading to cicatrization, i. 292; on the suppression of hæmorrhage, i. 309; on the means for keeping the lips of a wound in apposition, i. 323; on the use of sticking plaster or the dry suture for wounds, i. 325; on the use of sutures, i. 325; on gun-shot wounds, i. 335; on the character of gun-shot wounds, i. 338; objections to primary amputation, i. 345; on the cause of death in tetanus, i. 378; on the causes of tetanus, i. 379; on puncturing the dura mater, when the extravasation lies beneath it, i. 407; on the suppurative inflammation of wounded joints, i. 489; on rupture of the tendo Achillis, i. 492; on the treatment of the ruptured tendon, i. 492; on the period of union, and the manner in which it takes place in simple fracture, i. 500; on the consequences of compound fractures, i. 509; on the treatment of compound fracture, i. 515; on symptomatic fever, i. 521; on hectic fever, i. 522; on the removal of the injured limb during the continuance of hectic fever, i. 522; on the slight constitutional irritation after amputation, when union by the first intention takes place, i. 523; on the processes which follow after union has taken place in fractured patella, i. 579; on the formation of false joints, i. 588; on the treatment of false joints, i. 589; on the two modes in which the venereal poison affects the system, i. 641; on the period at which chancres appear after infection, i. 642; on the symptoms of chancre, i. 642; experiments by inoculating with the matter of gonorrhœa and chancre, i. 644; on the true venereal bubo, i. 645; on the existence of syphilitic buboes without primary sore, i. 646; on the continuance of the constitutional irritation from lues, independent of continued absorption, i. 647; on the non-infectious character of the pus from a secondary syphilitic sore, i. 649; on the relative rapidity of cure of gonorrhœa, chancre, and lues venerea, i. 654; on the relapse of ulcers after chancres have cicatrized; i. 655; case of diseased child infecting the nurse; i. 673; on the possibility of infection from secondary syphilis, i. 675; on the ossific inflammation preceding necrosis, i. 688; on the process of exfoliation, i. 691; on the signs of exfoliation, i. 692; on the species of exfoliation, i. 695; on the inadequacy of the term fistula, i. 710; on the causes of fistula, i. 710; on the cure of fistula, i. 711; objections to the use of the catheter in urethral fistula, i. 745; definition of aneurism, ii. 197; on the coagulation of blood in an aneurism, ii. 198; on the bursting of aneurism, ii. 199; on the relative frequency of aneurism in the sexes, ii. 203; on the relative frequency of aneurism in the arteries, ii. 203; admits a diseased state of an artery as the cause of aneurism, ii. 205; on the spontaneous cure of aneurism, ii. 206; on compression in the treatment of aneurism, ii. 210; claims to originality in reference to the Hunterian operation, ii. 215; on the size of the aneurism best fitted for operation, ii. 217; operation for tying the femoral artery in popliteal aneurism, ii. 219; cases of secondary hæmorrhage after the operation, ii. 224; on ligature of the femoral artery, ii. 263; description of three forms of stricture of the urethra, ii. 356; on the use of the armed bougie in stricture, ii. 366; case of retention of urine from calculus in the urethra, ii. 416; on the expulsion of bougies by the contractions of the bladder, ii. 418; operation for stone on infants, ii. 569; on cysts forming around foreign substances, ii. 694; on the internal surface of cysts, ii. 697; on the disposing causes of cancer, ii. 767; preference of secondary to primary amputation in severe injuries of the lower extremities, ii. 967; objections to primary amputations in such cases, ii. 967.

Hunter, Dr. William, on the structure of synovial membrane, i. 211; on the structure of cartilage, i. 223; Miescher differs in opinion with, respecting the fibrous structure of articular cartilage, i. 223; views on the structure of cartilage generally correct, i. 227; on aneurismal varix, ii. 269; on the distinction between aneurismal varix and false aneurism, ii. 271; on varicose aneurism, ii. 272; first suggests the small operation for ovarian dropsy, ii. 489.

Hunter, Robert, on the section of muscles in spinal curvature, ii. 169.

Hutchinson on incisions in pseudo-erysipelas, i. 108; on the rarity of calculus among seamen, ii. 545.

Hutton, Dr., on compression in the treatment of aneurism, ii. 211.

Hydatids, ii. 703.

Hydrarthrus, or hydrops articuli, i. 216; ii. 461.

Hydrocele, ii. 496.

Hydrocephalocele, ii. 98.

Hydrocephalus, ii. 464.

Hydro-mediastina, ii. 481.

Hydrometra, ii. 494.

Hydro-pericardium, ii. 478.

Hydrophobia:—bite of a rabid beast, i. 359; the bite of beasts much excited, or when disturbed during copulation, may produce canine madness, i. 360; causes of dog-madness, i. 360; spontaneous development of hydrophobia in man, i. 360; signs of incipient madness in the dog, i. 360; Hertwig's observations on canine madness, i. 360; progress of the disease, i. 361; signs of dumb madness in the dog, i. 361; Youatt on rabies in the dog, i. 361; Youatt on the peculiar bark of the mad dog, i. 362; Youatt on the saliva of the mad dog, i. 363; Youatt on the condition of the lumbar portion of the spinal cord in rabies and dumb madness in the dog, i. 363; Youatt on a peculiar paralysis of the muscles of the tongue and jaws occasionally occurring in mad dogs, i. 363; Youatt on the insensibility to pain in mad dogs, i. 363; Youatt on the diagnosis between pain in the ear in canker and in hydrophobia in the dog, i. 363; Youatt on the period of incubation of rabies in the dog, i. 364; Hertwig's experiments show that the saliva is the vehicle of the mad poison, i. 364; Trolliet considers the mucus from the inflamed mucous membrane of the bronchi to be the vehicle of the poison, i. 364; Hertwig's experiments also show the contagion to be in the blood of the mad beast, i. 364; Youatt on the appearances on dissection in the dog, i. 364; Youatt's caution against suffering dogs to lick the face or hands, or any other part of the body, i. 365; Lawrence's details of the Hon. Mrs. Duff's case, i. 366; Lawrence on the communication of hydrophobia from one human being [illegible] another, or from man to beasts, i. 366; Magendie and Breschet's experiment, i. 366; period of incubation of hydrophobia in man, i. 366; Galen, Mead, and Hale Thomson on the protraction of the period of incubation, i. 366: Dr. Bardsley's case of the disease twelve years after the bite had been inflicted, i. 367; his opinion that the case was not one of hydrophobia, i. 367; supports his opinion by the views of Darwin, Haygarth, and R. Pearson, i. 367; Elliotson on the period of incubation of the disease, i. 367; Professor Dick on the nature of the disease in hydrophobia, i. 367; symptoms of incipient hydrophobia, i. 367; Urban's opinion that there is a circlet of small vesicles round the wound or scar, i. 368; general symptoms of hydrophobia, i. 368; Elliotson on the symptoms of hydrophobia, i. 368; Elliotson on the diagnosis between true and spurious hydrophobia, and inflammation of the pharynx, i. 369; the disposition of hydrophobic patients to bite, doubted by South, i. 369; Powell and Magendie's cases, i. 369; Cline jun. on the disposition of hydrophobic animals to use their weapons of offence, i. 369; Elliotson on a general morbid irritability in hydrophobia, i. 369; Youatt on the peculiar delirium in hydrophobia, i. 369; Bardsley and Babington's cases illustrative of this delirium, i. 369; Lawrence on the peculiar delirium of hydrophobia, i. 370; Youatt on the tenacity of the human saliva in hydrophobia, i. 370; Elliotson on the duration of the disease, i. 370; Mead on the increase of muscular strength in hydrophobia, i. 370; Elliotson on abortive hydrophobia, i. 370; Dr. Bardsley on the stages of hydrophobia, i. 370; Marcet, Babington, and Callisen on the premonitory pains of hydrophobia, i. 371; post-mortem appearances in hydrophobia; i. 371; Locker on vesicles on the spleen in hydrophobia in dogs, i. 371; the post-mortem appearances in Elliotson's case, i. 371; the proximate cause of hydrophobia, i. 371; Harder on the action of the poison on the system, i. 372; Langenbeck on hydrophobia, as caused by a qualitative alteration of the blood by the poison, i. 372; prognosis, i. 372; treatment of the bite, i. 372; Youatt's objections to excision of the bitten parts, i. 372; South on the excision of the bitten parts, i. 373; Cline's directions for the excision of the bitten parts, i. 373; South on the excision of the scar, i. 374; internal prophylactics of hydrophobia, i. 374; plan of treatment recommended by Wendt, i. 374; Brera and von Schallein's treatment, i. 374; Marochetti on the presence of pustules under the tongue after the bite of a mad animal, i. 375; Marochetti's plan of treatment, i. 375; Watson's objections to Marochetti's views, i. 376; general treatment of hydrophobia, i. 376.

Hydro-thorax, ii. 469.

Hypospadias, and its treatment, ii. 374.

Hysterical Affections of the Joints. *See* Inflammation of the Joints.

Iliac aneurism, ii. 254.

—— artery, common, ligature of, ii. 255; internal, ligature of, ii. 256; external, ligature of, ii. 259.

Ilium, fracture of, i. 544.

Incised wounds, i. 329. *See* Wounds.

Induration, or hardening, i. 52.

INFLAMMATION, definition of, i. 22; the term objected to by Andral, and that of hyperemia substituted, i. 22; Hunter's opinions on inflammation, i. 22; Müller's, i. 22; all organs of the body may become inflamed, except the cuticle, hair, and nails, i. 23; the capillary, vascular, and ganglionic nervous systems, the actual seat of inflammation, i. 23; Hunter on the susceptibility for inflammation, and the influence of the constitution with respect to its local effects, i. 23; symptoms of inflammation, i. 24; South on the attendant pain, i. 24; Dr. Alison's description of inflammation, i. 24; explanation of the symptoms, i. 24; the changed condition and increased plasticity of the blood shewn by the crusta inflammatoria, i. 25; comparison of the local appearances of inflammation, and those coming in with inflammatory fever, i. 25; the cause of the increased action of the nerves, i. 25; Travers and Hunter on the cause of the pain, i. 25; Henle's opinion that the exciting cause of inflammation operates through the nervous system, i. 25; its mode of action, i. 26; Hunter on the causes of inflammation, i. 26, 30; Travers' remark, that pain is not necessarily an attendant on inflammation, i. 26; Hunter and Travers on the attendant redness, i. 26; Hunter's experiments on the increase of heat, i. 27; Travers' remarks on that symptom, i. 27; Hunter and Cullen on the enlargement of the vessels, i. 27; Dr. John Thomson's observations on the variation of the current of the blood through the capillaries, resulting from the application of different substances, i. 27; Earle's comments on these, i. 28; Dr. Wilson Philip's experiments, i. 28; Gendrin's account of the steps by which the stagnation of the blood in inflammation is produced, i. 29; Dr. John Thomson's experiments repeated

by Travers, i. 29; Travers and Bennett on the oscillation attending the recovery of the circulation, i. 29; Wharton Jones' description of the phenomena of inflammation under the microscope, i. 29; Emmert and Vogel's description of *the same phenomena, i. 30; incidental causes of inflammation, i. 30; results of inflammation, i. 31. Resolution:—signs of resolution, i. 31; distinguished from the recession of inflammation, i. 31* · Dr. J. H. Bennett on the process of resolution, i. 31; Schönlein and Zimmermann on the elimination of the molecular fibrin, i. 32. *Exudation:*—period of its occurrence, and its results, adhesion and edema, i. 32; the term synonymous with effusion, i. 32; Dr. J. H. Bennett, Travers, Wharton Jones, and Hunter on the process of effusion, i. 32, 33; Gerber's subdivisions of effusion, i. 33; Gerber on the microscopic resemblance between the lymph-corpuscles and the exudation-corpuscles, i. 34; this resemblance denied by Gulliver, i. 34; Valentin on the exudation-corpuscles, i. 34. *Suppuration:*—a natural result of severe inflammation, i. 34; the secretion of pus, i. 34; formation of abscess, i. 34, 36; opinions of Simpson, De Haen, Morgan, Hunter, Brugmans, Pinel, Boerhaave, Bell, Gotter, Quesnay, Hoffmann, Grashuis, Stewart, Pearson, Hewson, E. Home, Berzelius, Gruithuisen, Fischer, Donné, Gluge, Valentin, Gueterbock, Wood, Bonnet, Mandt, Vogel, and E.V. Bibra relative to the formation of pus, i. 35; symptoms of approaching suppuration, i. 35; occurrence and signs of fluctuation, i. 36; symptoms of deep-seated suppuration, i. 36; hectic fever accompanies every considerable suppuration, i. 36; formation of the walls of an abscess, and the circumscription of the pus, i. 36; the circumscription of the pus does not take place unless the inflammation is connected with plastic exudation, i. 36; the walls of an abscess are secreting and absorbing surfaces, i. 36; resorption of pus, i. 36; metastatic abscesses, i. 36; Vogel and Bonnet on the effects of the resorption of pus, i. 36; Hunter on the cause and results of suppuration, i. 36; Valentin on the microscopic results of suppuration, i 37; Hunter on suppurative inflammation, i. 37; Travers on the lining membrane of an abscess, i. 38; Hunter and Travers on the circumstances which determine an abscess to the surface, i. 38; qualities of pure good pus, i. 38; formation of pus, i. 39: Travers on the purpose which the formation of pus serves in the economy, i. 39; Hunter on the qualities of pus and the pus-globules, i. 39; Hunter and Gulliver on the putrefaction of pus, i. 39; Senac on the globular structure of pus, i. 39; Gueterbock on the composition and chemical analysis of pus, i. 40, 41; composition of the serum of pus, i. 40; fatty vesicles discovered in the serum of pus by Henle, i. 40 *Gueterbock's discovery of pyine, i. 40; characters of pus-globules, i. 40; Mandt on the pus-globules, i. 40; discovery of the difference in size of the pus globules by Gueterbock, i. 41; Mayo describes pus-*globules as occasionally seen in healthy blood, i. 41; denied by Gulliver, i. 41; Gerber's account of the formation of pus, and of the reproductive organization in suppurating wounds, i. 41; Travers on the constitution of pus, i. 42; varieties of pus, i 43; distinguishing characters of laudable pus, and ichor or sanies, i. 43; the presence of globules in the serum proved by Bauer, Faraday, and Mandt, i. 43; characters of the albumen in pus, i. 44; Grassmeyer and Fischer on the distinguishing tests for pus and mucus, i. 44; Gruithuisen's microscopic tests for pus and mucus, i. 44; Gerber's description of ichor, puriform mucus, and serous exudation, i. 44; pus cannot be produced without inflammation, i. 44; cold or lymph abscess, i. 45; the diathesis purulenta, i. 45; abscess of congestion, i. 45; symptoms of cold abscess, i. 45; cold abscess not to be confounded with Hunter's collections of matter without inflammation, nor with the cold abscess of the surgeons of the Saracen school, the chronic abscess of modern surgeons, i. 45; South's case of cold abscess, i. 45; Dr. Rigby on puerperal abscess following contagious or adynamic puerperal fever, i. 47; Beinl, Rust, and others, regard the so-called lymph-swelling as being an extravasation of lymph, i. 48; Walther proves that the term lymph-swelling is incorrect, i. 48; Beinl's opinion that the strongest and most healthy are more subject to lymph-abscess than the weakly, and men than women, and that it does not occur without external injury disproved by Rust, i. 48; Nasse's case of lymph-swelling from external injury, i. 48; such cases exceedingly rare, i. 48; opinions of Langenbeck, Ekl, and Zembsch on the lymph-swelling, i. 48; South's case of lymph abscess, i. 49. *Ulceration:*—causes, i. 49; Hunter on ulcerative inflammation, i. 49; on ulcerative absorption, i. 50; progressive absorption, i. 51; absorption with suppuration, i. 51; Travers on the process of ulceration, i. 52. *Induration or Hardening:*—Causes and results, i. 52; occasional terminations in inflammation, ulceration, and cancer, i. 53; induration most likely to occur after long-continued

insidious inflammations in organs with a low degree of vitality, i. 53. *Softening* occurs only in long-continued dyscratic and cachectic inflammations, i. 53 ; may be regarded as the intermediate condition between ulceration and mortification, i. 53. *Mortification* :—divided into hot and cold, i. 53 ; Travers' objection to the terms mortification and sphacelus, i. 53 ; definition of mortification, i. 53 ; symptoms, i. 54 ; Travers' acute gangrene, i. 54 ; destruction of the mortified parts occurs either as dry, moist, or hospital gangrene, i. 54 ; South on vesications filled with a bluish or bluish-black fluid in cases of severe bruise, or when the bandages in cases of fracture are too tight, i. 55 ; causes of mortification, i. 55 ; Brodie on sudden loss of blood as a cause of mortification, i. 55 ; Travers on deep and extensive effusions, and injuries of nerves as causes of mortification, i. 55 ; South's case of mortification of the lower extremity from effusion of blood causing distension of the limb, i. 55 ; mortification in cases of aneurism caused by the distension from effusion, i. 56 ; mortification in cases of simple fracture, the principal artery being uninjured, i. 56 ; South's cases of mortification after fever, i. 56 ; senile gangrene, i. 57 ; distinction between senile gangrene consequent on injury, and that resulting from constitutional causes, i. 57 ; Travers' chronic gangrene, i. 58 ; causes of dry gangrene, i. 59 ; South's case of dry gangrene consequent on abdominal typhus, i. 59 ; Dupuytren on arteritis, a cause of dry gangrene, i. 59, 75 ; South's case of dry gangrene from organic disease of the heart, i. 59 ; Brodie's case of dry gangrene from inflammation of the principal artery and vein of the limb, i. 59 ; Brodie on the cause of the distinction between dry and moist gangrene, i. 59 ; gangrene from arterial inflammation, a comparatively rare disease, i. 59 ; this statement denied by Cruveilhier and Dupuytren, i. 59 ; South's case of arteritis without gangrene, i. 60 ; Solly's case of gangrene, i. 60 ; mortification from continued pressure, i. 60 ; mortification from the use of the spurred rye, i. 60 ; Thomson's account of this form of the disease, i. 61 ; Sigebert and Bayle's remarks, i. 61 ; the disease first noticed by Dodard, afterwards by Saviard, Noel, Langius, Quassoud, Bossau, and Duhamel, i. 61 ; Dr. Elliotson's case of gangrene of the leg, after the use of ergot, the arteries of the limb being ossified, i. 61 ; Model's opinion that spurred rye does not cause gangrene in brutes, i. 61 ; disproved by Tessier, i. 61 ; Block's experiments on the subject, i. 61 ; Dr. C. Woolaston's cases of gangrene, i. 61 ; mortification of the cheek, called "noma" by Vogel, i. 61 ; a rare and generally fatal disease, i. 61 ; description of noma by Drs. Evanson and Maunsell, i. 62 ; the term cancrum oris incorrectly applied to noma, i. 62 ; cancrum oris, a form of mortification commencing with ulceration, generally first in the gums, and thence spreading to the lips and cheeks, i. 62 ; described by Dr. Cumming, i. 62 ; South's case of noma in the adult, i. 62 ; mortification, when a consequence of contagious influence, results in malignant pustule, or hospital gangrene, i. 63 ; malignant pustule, its causes and symptoms, i. 63 ; contagious from beast to man, but not between man and man, i. 63 ; Elliotson on glanders in the human subject, i. 64 ; Lawrence's cases of malignant pustule, i. 64 ; Beer and Delpech's cases, i. 65 ; Turchetti's cases of malignant pustule, described by him as anthrax, i. 66 ; Dr. Wagner's cases of malignant pustule, produced by contact, and by eating the flesh of diseased animals, i, 66 ; Dr. Bourgeois' observations on malignant pustule, i. 67 ; hospital gangrene, i. 68 ; description of the disease, i. 68 ; local and general symptoms, i. 68 ; Liston's account of the hospital gangrene in University College Hospital in 1841, i. 68 ; Arnott's cases of hospital gangrene at the Middlesex Hospital, i. 69 ; the disease excedingly rare in the London hospitals, i. 69 ; Lawrence on sloughing phagedena, i. 69 ; Welbank on sloughing phagedena, i. 70 ; this disease regarded by S. Cooper as resembling hospital gangrene, i. 70 ; denied by South, i. 70 ; South on the sloughing state of stumps from want of power, i. 70 ; the characteristics of hospital gangrene, i. 70 ; the cause of hospital gangrene is the operation of a peculiar contagious matter, i. 70 ; it is always a very dangerous complication of wounds and sores, i. 70. VARIETIES OF INFLAMMATION :—inflammation may be classed, 1st, according to its appearances and course ; 2ndly, according to its causes ; and 3rdly, according to the structure of the parts attacked, i. 71 : acute and chronic inflammation, i. 71 ; division of inflammation into simple, erethitic, torpid, malignant, and obscure, i. 71 ; idiopathic, symptomatic, specific, and sympathetic, i. 71 ; metastatic inflammation, i. 72 ; inflammation of the skin, i. 72 ; of the cellular tissue, i. 72 ; South on inflammation of the cellular tissue, i. 72 ; inflammation of the glands, i. 72 ; of the mucous membranes, i. 72 ; Hunter on inflammation of the mucous membranes, i. 73 ; inflammation of serous membranes, i. 73 ; Hunter on inflammation of serous membranes, i. 73 ; South on the tendency of serous membranes to adhesive inflammation, i. 73 ; Hunter on

the occasional termination of inflammation of serous membranes in suppuration, i. 74; inflammation of the fibrous tissues, i. 74; inflammation of the coats of arteries, arteritis, i. 74; Bouillaud on arteritis, i. 74, 75; Hodgson's cases of arteritis, i. 74; Portal's case of inflammation of the aorta, consequent on the recession of measles, i. 74; redness not always present in inflamed arteries, and sometimes occurs when there is not any inflammation, i. 75; Bouillaud on the redness of the internal arterial membrane, i. 75; Dupuytren on mortification as the result of arteritis, i. 75; South's case of arteritis, i. 75; Portal on the ossification of arteries in young children, i. 77; Brande's analysis of the earthy concretions in arteries, i. 77; Miescher on the ossification of arteries, i. 77; inflammation of veins, phlebitis, i. 77; causes, symptoms, and terminations, i. 77; Cruveilhier on phlebitis, i. 77; South on phlebitis, i. 77, 78; Hunter on the coagulation of the blood in phlebitis, i. 77; Hunter, Abernethy, Hodgson, Carmichael, Bouillaud, Travers, and Arnott, on severe phlebitis, i. 78; Ribes' cases of phlebitis, i. 79; Arnott on the morbid appearances in phlebitis, i. 80; Dr. Robert Lee on inflammation of the femoral and iliac veins, an occasional cause of phlegmasia dolens, i. 80; inflammation of the absorbent vessels, i. 80; South on the causes of inflammation of the absorbent vessels; i. 80; Hunter on the red streaks accompanying inflammation of the absorbents, i. 81; South on earthy deposit in the absorbents, i. 81; inflammation of the nerves, or their sheaths, i. 81; of the bones, i. 81; of the periosteum, i. 81, of the medullary membrane, i. 81; prognosis of inflammation, i. 82; treatment, i. 82; the first indication to induce resolution, i. 82; employment of antiphlogistic remedies, i. 82; in erethitic inflammation, opium combined with proper antiphlogistic means, should be exhibited, i. 82; gastric impurities should be removed by vomiting and purging, i. 82; in malignant, specific, and dyscratic inflammations, antiphlogistic remedies should be used cautiously, i. 82; Hunter on inducing resolution by constitutional means, i. 82; Hunter's directions respecting the employment of blood-letting, i. 82; local treatment of inflammation by abstraction of blood, cold, moist, or dry warmth, salves, and plasters, astringent, anodyne, and derivative means, i. 83; Hunter on the local means of inducing resolution, i. 83; local bleeding by leeches, scarifications, and cupping-glasses, i. 84; employment of cold, i. 84; ice or freezing mixtures must not be used too long, lest they destroy the vitality of the part, i. 84; moist, warm remedies, fomentations, and poultices, i. 84; Hunter on fomentations or steams, washes, and poultices, i. 85; Abernethy on poultices, i. 85; medicated poultices, i. 85; treatment of torpid inflammation, i. 86; derivative remedies, i. 86; Hunter on derivation, i. 86; treatment of receding inflammation, i. 86; treatment after exudation has taken place, i. 87; treatment during and after suppuration, i. 87; when the abscess is ripe, it either opens of itself, or it must be opened, i. 87; small abscesses just beneath the skin, and those in glandular structures, should alone be allowed to burst, i. 87; circumstances under which the early opening of abscesses is required, i. 87; circumstances under which abscesses are opened late, i. 87; South recommends the early opening of abscesses just beneath the skin, and in glandular structures, i. 87; opening of abscesses, oncotomia, effected by the knife, escharotics, or the seton, i. 88; deep abscesses with thick coverings, should be opened with a bistoury, i. 88; South's condemnation of pressure and squeezing an abscess, i. 88; mode in which escharotics are employed, i. 89; passing a seton through an abscess, i. 89; opening an abscess with a cutting instrument generally preferable, i. 89; South on the opening an abscess, i. 89; treatment of cold abscess, i. 90; various plans of opening a cold abscess, recommended by Abernethy, Beinl, Walther, Schaack, Rust, Nasse, Zang, and Callisen, i. 90; in selecting his plan of operating, the Surgeon must be guided by the difference of constitution, by the more or less weak state of the cellular walls, and by the size of the swelling, i. 90; constitutional treatment also required, i. 91; Kluge's plan of treating lymph-abscesses, i. 91; further treatment after opening the abscess, i. 91; if there be deficiency of power in the part, stimulants may be used, but moist warm poultices are more effectual, i. 92; tonics may be given internally, i. 92; if the opening close too soon, the edges may be drawn asunder, or separated with a probe, i. 92; proud flesh repressed by caustic, i. 92; formation of fistulous passages, i. 92; membrane of the fistula first pointed out by Hunter, since described by Villermé, Laennec, and Breschet, i. 92; Hunter's description of the membrane of the fistula, i. 92; treatment of the fistulous passage, i. 93; plans of treatment recommended by Langenbeck, H. Dewar, Cramer, Walther, and others, i. 93; Langenbeck's recommendation of the ligature, i. 93; attention to the general health requisite during suppuration, i. 93; treatment of induration,

i. 93 ; first indication to promote resolution, i. 93 ; the second, its removal by the knife, i. 94 ; treatment of gangrene, i. 94 ; when connected with active inflammation, and inflammatory fever, moderate antiphlogistic treatment to be employed, i. 94 ; if caused by the constriction of unyielding aponeuroses, they must be divided, i. 94 ; when connected with general debility, tonics and mineral acids indicated, i. 94 ; local treatment of gangrene, i. 94 ; if there be active inflammation, soothing poultices; if the part be free from pain and shrivelled, stimulant applications are required, i. 95 ; remedies which prevent the influence of the gangrenous juices, i. 95 ; their action aided by scarifications in the gangrenous parts, i. 95 ; the latter must not penetrate into the living parts, i. 95 ; scarifications are dangerous in gangrena senilis, i. 95 ; amputation not applicable in gangrene depending on an internal cause still in operation, i. 95 ; applicable after the line of demarcation has formed, or in gangrene from external violence, even while still proceeding, i. 95 ; South's opinion that amputation should never be performed while the gangrene is in progress, i. 95 ; treatment of senile gangrene, i. 96 ; when resulting from an injury, soothing or dry aromatic applications, or leeching if the inflammation be active, i. 96 : Dupuytren employs the antiphlogistic plan of treatment in plethoric subjects, i. 96 ; when from constitutional causes, tonics and opium are necessary, i. 96 ; treatment of gangrene from pressure, i. 96 ; from the use of spurred rye, i. 96 ; Thomson and S. Cooper's cases, i. 97 ; treatment of malignant pustule, i. 97 ; local treatment by cutting out the pustule, and cauterizing the wound, i. 97 ; if pustule not deep, but the slough much spread, deep scarifications, and the application of caustic recommended, i. 97 ; employment of constitutional treatment, i. 97 ; treatment of hospital gangrene, i. 97 ; emetics advised by Pouteau and Dussausoy, i. 97 ; washing the sore with vinegar, or solution of arsenic at the commencement of the disease, i. 97 ; the entire surface to be touched with nitrate of silver, i. 98 ; the free application of the actual cautery most effectual, i. 98 ; constitutional treatment should be employed at the same time, i. 98.

INGLIS, Dr., on the age at which bronchocele most usually occurs, ii. 655 ; objections to Coindet's mode of exhibiting iodine, ii. 660.

INGROWING OF THE NAIL, i. 198 ; causes, i. 198 ; Wardrop and Dupuytren on ingrowing of the nail, i. 198 ; Dupuytren states it has been mistaken for gout, i. 199 ; Colles on the ingrowing of the nail, i. 199 ; Colles on the disease of the nail liable to be mistaken for gout, i. 199 ; treatment in slight cases, i. 199 ; Desault, Richerand, and Biessey's plans of treatment, i. 199 ; Zeis on the introduction of charpie under the edge of the nail, and the use of foot-baths, i. 200 ; Meig's plan of treatment by a compress and linen-roller, i. 200 ; Sir A. Cooper says the application of a blister will bring away the nail, i. 200 ; this opinion contravened by South, i. 200 ; Dupuytren's operation for dividing and removing the diseased nail, i. 200 ; Scoutteten's operation for the destruction of the matrix of the nail, i. 200 ; the operation recommended by Paré, Faye, Michaelis, Sachs, and Zeis, i. 200 ; Sir Astley Cooper's operation, i 200 ; Colles and South condemn Cooper's operation, i. 201 ; Colles' operation, i. 201 ;

Inguinal rupture and its varieties, ii. 54.

Innominata, ligature of, ii. 245.

Internal strangulation, ii. 94.

INTESTINES, WOUNDS OF, i. 462 ; symptoms, i. 462 ; Travers, Green, Tyrrell, and South's cases of wounded intestines, i. 462 ; Travers on wounds of the intestines communicating directly with the surface, i. 463 ; varieties of wounds of the intestines, i. 463 ; Travers on the varieties of wounds of the intestines, i. 463 ; difference of opinion as to the treatment of wounded and protruded intestine, i. 463 ; different kinds of stitches employed, i. 463 ; Scarpa and Larrey's practice, i. 464 ; Denans, Béclard, Jobert, Lembert, and Reybard's practice in wounded intestine, i. 464, 465 ; Shipton and Travers' experiment, i. 465–7 ; Else, Benjamin Bell, John Bell, and Hennen on the use of the suture in wounded intestine, i. 466, 467 ; objections to the use of stitches in wounded intestine, i. 467 ; reasons in favour of their use, i. 468 ; Travers on the objections to returning a wounded intestine, without suture, into the abdomen, i. 468 ; Travers and Benjamin Bell on the withdrawal of the suture, after union has taken place, i. 468; Travers' directions for stitching a wounded intestine, i. 468 ; approval of Lembert's plan, i. 469 ; Astley Cooper's practice in small wounds of the intestines, i. 469 ; Dupuytren's modification of Lembert's plan, i. 469 ; Travers on the reparation by artificial connexion of the divided parts of a wounded intestine, i. 470 ; treatment of a perfectly divided intestine, one end only being found, i. 470 ; treatment of wounded intestine, i. 470 ; treatment of wounded intestine when the fæces escape by the wound, i. 471 ; Travers and South on the treatment of wounded intestine without fæcular discharge or prolapse, i. 471 ;

Travers on spontaneous reparation in wounded intestine, i. 471; contraction of the intestine sometimes the result of a wound, i. 471; effusion of fæcal matter, blood, or other fluid, constitutes the most dangerous complication of penetrating wounds of the abdomen, i. 471; Travers and Hennen on effusion into the cavity of the abdomen under such circumstances, i. 472; extravasation of the intestinal contents, i. 472; Travers on the impediments to effusion of the intestinal contents, i. 472; symptoms of effusion, i. 473; effusion of blood into the cavity of the abdomen, i. 473; the effused blood is either collected in a circumscribed space, or diffused over the abdomen, i. 473; treatment of extravasation, i. 473; Hennen's case of musket-shot wound of the abdomen, the ball passing afterwards per anum, i. 474; foreign bodies in the intestines, ii. 388.

Introduction:—definition of surgery, i. 1; division of, i. 3.

Ippolito, Nunciante, on ligature of the vertebral artery, ii. 250.

Ireland on the use of arsenic in the bites of the great lance-headed viper of Martinique, i. 359; operation for prolapsus uteri, ii. 112.

Ischiatic artery, ligature of, ii. 258.

———— rupture, ii. 86.

Ischuria, and its varieties, ii. 409.

Issues, making of, ii. 869.

Jacobson's lithotritic instrument, advantages and disadvantages of, ii. 560.

Jacquier's case of reduction of the consecutive dislocation in hip disease, i. 268.

Jaeger on the mercurial treatment in hip disease, i. 267; on the general treatment of coxalgy, i. 267; views on the reduction of consecutive dislocation in coxalgy, i. 268; on the treatment of abscesses of the hip, i. 269; recommends free incisions in opening these abscesses, i. 269; excision of the carious head of the thigh-bone recommended by, i. 270; opinion that the preparations of fractured spine united by callus, only show that the fracture may be cured, but not the palsy, i. 532; on the operation for trepanning a fractured spine, i. 538; treatment of fractured clavicle, i. 552; case of imperfect fracture of the coronoid process of the ulna, i. 562; on the inlocking of the ends of the bone in fracture of the neck of the femur, i. 564; objection to dressing the wound after the operation for rectal fistula, i. 731; on the division of the sphincter muscle in recto-vesical and recto-urethral fistula, i. 748; on the treatment of vesico-vaginal fistula by drawing off the urine, and by compression, i. 752; on the nature of strangulation in rupture, ii. 11; on the seat of exostosis, ii. 673; on the blood fungus, ii. 722; plan of amputating the thigh with the flap from the outer side, ii. 909; on amputation at the hip-joint, ii. 933; mode of operating by the circular cut, ii. 934; on the statistics of the operation for exarticulation of the leg at the knee, ii. 943; mode of operating in exarticulation of the fore-arm at the elbow, ii. 962; case of excision of part of the hand, ii. 965; on the excision of joints, ii. 969; statistics of cases, ii. 970; recommends the non-division of the ulnar nerve in excision of the elbow-joint, ii. 975; mode of operating in excision of the elbow-joint, ii. 976; in excision of the lower ends of the radius and ulna, ii. 976; in excision of the knee-joint, ii. 981; on the mode of union after the operation, ii. 982; mode of operating in excision of the ancle-joint, ii. 983; on excision of the lower jaw with the condyles, ii. 989; on the previous ligature of the carotid artery, ii. 990.

James' case of dislocation of the astragalus outwards, i. 810; case of ligature of the aorta, ii. 254; case of tearing away the upper arm and scapula by machinery, ii. 1003.

Jameson's plan of inhealing a plug of skin for the radical cure of rupture, ii. 24; instrument for œsophageal stricture, ii. 323; treatment of stricture of the urethra, ii. 372.

Jamieson's case of accidental cerebral rupture, ii. 100.

Janson's case of resection of the scapula, ii. 1002.

Jaw, lower, fracture of, i. 528; dislocation of, i. 770; excision of, ii. 986; cases requiring the operation, ii. 986; circumstances admitting a favourable result, ii. 986; priority of claim as originator of the operation, ii. 986; Tyrrell's case of necrosis of the lower jaw, ii. 986; *excision of the middle of the lower jaw*, ii. 987; mode of operating, ii. 987; retraction of the tongue, ii. 987; Dupuytren, Graefe, and Astley Cooper's cases, ii. 987; *removing a portion of the side of the lower jaw without the condyle*, ii. 988; mode of operating, ii. 988; Deadrick, Mott, and Wardrop's cases, ii. 988; *excision of the lower jaw with its condyles*, ii. 989; Mott, Schindler, von Graefe, Syme, Jaeger, and Cusack's modes of operating, ii. 989; Mott, von Graefe, Dzondi, Jaeger, and Schindler on the previous ligature of the carotid artery, ii. 990; White's case of excision of the lower jaw, ii. 991; Graefe and Mott's cases of exarticulation of one side of the lower jaw, ii. 992; Cusack on the non-necessity of tying the carotid artery prior to the operation, ii. 993;

Cusack's cases of exarticulation of the lower jaw, ii. 993; Liston's mode of operating, ii. 993; Perry's case of necrosis of the lower jaw, ii. 994.

Jaw, upper, fracture of, i. 527; resection of, ii. 994; cases in which the operation is indicated, ii. 994; Dupuytren's cases of extirpation of the upper jaw doubted by Gensoul, ii. 994; Akoluthus' case, ii. 994; Dr. T. White's case of almost complete extirpation of the upper jaw, ii. 994; mode of operating, ii. 995; section of the skin and muscles, according to Gensoul and Dieffenbach, ii. 995; Lizars the first to recommend the entire removal of the upper jaw, ii. 996; his description of the proposed operation, ii. 996; Lizars' cases in which he attempted to perform the operation, but failed on account of the hæmorrhage, ii. 996; Lizars' cases in which he performed the operation, ii. 996; Gensoul's case of extirpation of the superior maxillary bone, ii. 997; cutting away the diseased jaw, ii. 997; Heyfelder's operation for the resection of both jaws, ii. 998; Syme, Liston, and Fergusson's modes of operating, ii. 968; O'Shaugnessy's case of removal of the upper jaw, ii. 999; Hetling's case of osteosarcoma of the jaws, in which he removed part of the upper, and part of the lower jaw, ii. 1000; Liston on the prospect of ultimate success in this operation in cases of malignant disease, ii. 1001; dressing the wound, and after-treatment, ii. 1001; dangerous symptoms which may occur after the operation, ii. 1001; recurrence of the disease, ii. 1001.

Jeaffreson on the extirpation of the ovary, ii. 487; case of extirpation of the ovary, ii. 489; on the statistics of the operations for the extirpation of the ovary, ii. 490.

Jenner's, Dr., discovery of vaccination, ii. 873.

Jewel, Dr., on the distinguishing signs between leucorrhea and gonorrhea, i. 160.

Joachim's artery-compressor, i. 299.

Jobert's practice in wounded intestine, i. 464; on the introduction of the seton in false joints, i. 593; on the treatment of vesico-vaginal fistula by transplantation, i. 757; case of ligature of the popliteal in the internal epichondyloid pit, ii. 265.

Johnson's, Dr., case of obstruction of the rectum by a large collection of peas, ii. 392.

Joints, excision of, ii. 968; first performed on the knee-joint, ii. 968; afterwards extended to the other joints, ii. 968; Filkin, Vigaroux, David, White, Bent, Orred, Park, Moreau, Graefe, and Davie's cases, ii. 968; Sabatier, Percy, Roux, Moreau, Larrey, Guthrie, Syme, Textor, and Jaeger on the excision of joints, ii. 969; Wachter, Vermandois, Kohler, and Chaussier's experiments, ii. 969; objections to this operation as compared with amputation, ii. 969; advantages of the operation, principally referable to the joints of the upper extremities, ii. 969; not so great in operations on the other joints, ii. 969; statistics of Jaeger, Syme, and Moreau's cases, ii. 970; Crampton on the excision of joints, ii. 970; cases in which excision of the ends of bones is preferable to amputation, ii. 970; contra-indications to the operation, ii. 971; mode of operating, ii. 971; direction and extent of the incision in the skin, ii. 971; excision of the diseased bone, ii. 971; extent of bone required to be removed, ii. 972; instruments for excising the ends of bones, ii. 972; arrest of the subsequent hæmorrhage, ii. 972; dressing the wound, ii. 972; after-treatment, ii. 972; untoward occurrences during the after-treatment, ii. 973; after-bleeding, ii. 973; abscesses, ii. 973; fistulous passages, ii. 973; necrosis of rare occurrence after this operation, ii. 973; after-treatment of the sawn ends of the bone, ii. 973; *excision at the shoulder-joint*, ii. 974; mode of operating in excision of the head of the humerus, ii. 974; C. White, Orred, Bent, Sabatier, Moreau, and Syme's modes of operating, ii. 974; motions of the arm subsequent to the operation, ii. 974; *excision of the elbow-joint*, ii. 975; Moreau's mode of operating, ii. 975; Dupuytren and Syme's modes of operating, ii. 975; Moreau on the division of the ulnar nerve in this operation, ii. 975; Dupuytren, Crampton, Jaeger, and Syme recommend its preservation, ii. 975; Jaeger's mode of operating, ii. 976; condition of the arm after excision of the elbow joint, ii. 976; Crampton and Syme's cases, ii. 976; *excision of the wrist-joint*, ii. 976; Roux and Jaeger's modes of operating in excision of the lower ends of the radius and ulna, ii. 976; dressing the wound and after-treatment, ii. 977; Dubled and Velpeau's operations, ii. 977; Butt's case of excision of part of the necrosed ulna, ii. 977; *excision of the hip-joint*, ii. 977; mode of operating, ii. 977; by a simple longitudinal cut, ii. 977; by the formation of a flap, ii. 977; by Textor's oval cut, ii. 978; dressing the wound, ii. 978; White, Carmichael, Oppenheim, Hewson, Seutin, and Textor's cases, ii. 978; C. White on excision of the head of the femur, ii. 979; A. White and Fergusson's cases of excision of the head of the femur, ii. 979; *excision of the knee-joint*, ii. 981; Moreau, Park, Mülder, Sanson, Bégin, Jaeger, and Syme's modes of operating, ii. 981; Jaeger's operation preferred, ii. 981; Moreau, Park, and

Jaeger on the mode of union after the operation, ii. 982; Syme on the treatment after the operation, ii. 982; A. White's case of compound dislocation of the femur behind the leg, ii. 982; *excision of the ancle-joint*, ii. 983; Moreau, Jaeger, Mülder, and Kerst's modes of operating, ii. 983; South on excision of the ancle-joint, ii. 984; dressing the wound, and after-treatment, ii. 985; *excision of the joints of the metacarpus and metatarsus*, ii. 985; mode of operating, ii. 985; after-treatment, ii. 985; Textor, Kramer, Roux, and Fricke's cases, ii. 985.

Joints, Inflammation of:—inflammation may be set up as the primary disease in any part of the joints, such as the ligaments, synovial membranes, cartilages, and spongy ends of the bones, i. 205; Hunter on inflammation of the joints, i. 206; causes and nature, i. 206. *Inflammation of the ligaments*, i. 206; Brodie on the rarity of affections of the ligaments independent of other structures, i. 206; Mayo's case of injury to the ligaments of the knee, i. 206; Wickham's observations on inflammation of the ligaments, i. 207; symptoms of acute inflammation of, i. 207; South on the absence of discriminating signs between acute inflammation of the ligaments and rheumatism, i. 207; symptoms of chronic inflammation of the ligaments, i. 207; terminations of the acute and chronic form of inflammation, i. 208; changes of structure in the joints, i. 208; Key on ulceration in ligamentous fibre, i. 208; South on relaxation of the ligaments, i. 209; treatment of inflammation of, i. 209; treatment of thickening and swelling of the cellular tissue, i. 209; of suppuration external to the joints, i. 209; of suppuration internal to the joints, i. 209; this latter malady is Wickham's disease of the cellular membrane of joints, i. 210; Wickham's description of the disease, i. 210; South's cases of abscesses external to the joint, i. 210; South on the position of the limb during disease of the knee-joint, i. 211; *inflammation of the synovial membrane*, i. 211; W. Hunter on the structure of synovial membrane, i. 211; Henle on the continuity of synovial membrane over the cartilage of joints, i. 212; Toynbee on the synovial membrane, i. 212; Clopton Havers, and Goodsir on the mucilaginous glands, i. 212; Brodie on the diseases of the synovial membranes, i. 213; symptoms of inflammation of, i. 213; Brodie on the two varieties of synovial inflammation, i. 213; Brodie's case of acute synovial inflammation terminating in suppuration and ulceration, i. 214; Wickham's case of synovial inflammation terminating in ulceration, i. 214; suppuration of the synovial membrane, after wound of the joint, i. 214; Brodie on the subacute or chronic form of synovial inflammation, i. 215; symptoms and progress of the disease, i. 215; Lawrence on the diagnosis of fluctuation in synovial inflammation, i. 216; Lawrence on hydrarthrus or hydrops articuli, i. 216; Dr. Watson on the difference between synovial inflammation and inflammation of the ligaments, i. 216; Astley Cooper on gonorrheal rheumatism and gonorrheal ophthalmia, i. 217; Cooper's case of gonorrheal rheumatism and ophthalmia, i. 217; Brodie on gonorrheal rheumatism and ophthalmia, i. 217; Brodie and Lawrence on the pulpy degeneration of the synovial membrane, i. 217; South on the non-malignancy of this pulpy degeneration, i. 218; Brodie on its causes and progress, i. 218; post-mortem appearances, i. 218; South on the nature of the respective diseases, as indicated by the post-mortem appearances, i. 219; causes of synovial inflammation, i. 219; prognosis, i. 219; treatment, i. 219; Brodie and South on the local treatment, i. 219; if suppuration ensue, the swelling should be punctured early, i. 220; treatment to be adopted, after the inflammation is subdued, there remaining swelling from effusion of fluid, i. 220; South on the use of blisters for promoting the absorption of the effused fluid, i. 220; Brodie on the use of friction in such cases, i. 220; treatment of the chronic form of inflammation, i. 221; after the occurrence of suppuration, with destruction of the cartilages and bones, i. 221; South on irritant applications in the treatment of the chronic form of the disease, i. 221; South's case of disease of the synovial membrane of the knee-joint, attended with evidence of fluctuation, in which the swelling was punctured without benefit, i. 222: *Inflammation of the cartilages*, i. 222; William Hunter on the structure of cartilage, i. 223; Miescher says "no difference between permanent cartilage and that which is to be converted into bone," i. 223; he differs in opinion with W. Hunter as respects the fibrous structure of articular cartilage, i. 223; Todd and Bowman consider there is a difference between temporary and articular cartilage, i. 224; Henle on the fibrous structure of articular cartilage, i. 224: Henle and Toynbee on the non-vascularity of cartilage, i. 224, 225; Toynbee on the development of cartilage, i. 225; Toynbee on the supply of nutrient fluid to articular cartilage, i. 225; Toynbee on the vessels by which the articular cartilages are nourished, i. 226; Toynbee's description of the canals

in adult cartilages, i. 226; Meckel, Bichat, and Müller on the vessels of cartilage, i. 226; Brodie's opinion that cartilages are vascular, i. 227; Toynbee, Béclard, and Cruveilhier distinctly of opinion that cartilages are devoid of vascularity, i. 227; W. Hunter's views on the structure of cartilage generally correct, i. 227; symptoms of inflammation of cartilage, i. 227; Mayo on three distinct forms of ulceration of joint-cartilages, i. 228; Wilson on inflammation of cartilage, i. 228; Hunter, Wilson, and Brodie, on the ulcerative absorption of, i. 228, 229; Lawrence on ulceration of cartilage as an original affection of the joints, i. 229; Key on the conditions under which ulceration of the cartilages is effected, i. 229; Key on the absorption of cartilage by a new membrane produced by inflammation of the synovial membrane, i. 229; Key on the progress of ulceration in cartilage, i. 230; Goodsir holds with Key that the deposit from the synovial membrane is the cause of ulceration in cartilage, i. 231; accordance of Key's views with those of Wilson, i. 232; Key on the changes in the synovial membrane, when suppuration is the result of a wound in it, i. 232; they induce ulcerative absorption of the articular cartilages, i. 232: Brodie does not accord with Key's views, and considers that absorption of cartilage may take place under such circumstances as to admit of no other agency than that of the vessels of the cartilage, i. 233; Lawrence's case of rapid ulceration of cartilage, i. 234; Lawrence on the necrosis of long bones as a cause of inflammation and absorption of cartilage, i. 234; Key on the formation of an adventitious membrane in joints under such circumstances, i. 234; this is a repairing process, preparatory to anchylosis, i. 234; Henle explains the absorption of cartilage from want of nutriment, i. 234; Key on ulceration of cartilage, an action altogether different from absorption, i. 235; Key on the process of ulceration generally, i. 235; Key on the process by which ulceration of the cartilage is effected, i. 235; it leads to the formation of abscess, i. 235; post-mortem appearances, i. 236; Schumer and Gendrin never found any trace of inflammation in cartilage, i. 236; Brodie and South consider ulceration of cartilages differs from common inflammation of the synovial membrane, and of the spongy ends of bones, i. 236; Brodie on the degeneration of cartilage into a fibrous structure, i. 236; this change Key describes as the third mode of ulceration of cartilage, i. 236; causes of the disease, i. 237; Brodie on the period at which ulceration of the articular cartilages may occur, i. 237; prognosis always unfavourable, i. 237; treatment, i. 237. *Inflammation of the joint-ends of bones*, i. 237; symptoms, i. 237; Brodie on inflammation of the joint-ends of the bones, its symptoms and progress, i. 238; Brodie on the consequence of this inflammation, i. 238; Key on the two forms of disease in the bone, resulting in absorption of the cartilage, i. 238; the chronic form is of a strumous nature, i. 238; the acute form differs from the former in the suddenness of the attack, and in the appearance of the bone, i. 238; progress of the acute disease, and appearance of the bone, i. 239; Goodsir on the scrofulous disease of the cancellated texture of the heads of bone, i. 239; post-mortem appearances, i. 239; situation and causes of the disease, i. 239; Brodie and Key on the period at which it is likely to occur, i. 239; Brodie observes that it is likely to occur in several joints at once, or in succession, i. 239; Brodie and South's opinion that the occurrence of scrofulous disease in the joint has suspended the progress of some other and perhaps more serious disease elsewhere, i. 240; Brodie on the diagnosis between scrofulous disease of the joint-ends of bones and ulceration of the articular cartilages, i. 240; prognosis and treatment, i. 240; *favourable consequences of ulceration of the cartilages*, i. 240; may occur in one of two ways, i. 240; in the first the cartilage is replaced by a layer of ivory-like bone, and the motions of the joint continue, i. 240; in the second, the opposed ends of the bones are united, either by a ligamento-fibrous structure, or by bone, i. 240; South has seen the connecting medium composed partly of ligamento-fibrous, and partly of bony matter, i. 240; South on the ivory-like covering of the joint-surfaces of bones, i. 240; Key and Toynbee on the removal of the articular cartilages in old age i. 241; South and Brodie on the removal of the articular cartilages in old age as the result of previous ulceration, i. 241; John Hunter on anchylosis, i. 241; anchylosis effected by the whole substance of the articulation, i. 241; of two kinds, i. 241; Hunter on the inflammatory and scrofulous diseases of joints causing anchylosis, i. 242; Hunter on soft anchylosis from granulations, i. 242; Hunter on bony anchylosis, i. 242; South's views on anchylosis differ somewhat from those of Hunter, i. 242; South on soft anchylosis from granulations, i. 242; Key on the formation of a vascular membrane in joints as a preliminary to anchylosis, i. 242; South's case of fibrous anchylosis, i. 243; South's case of the complication of bony and fibrous anchylosis, i. 245;

Hunter's case of soft anchylosis from the extension of inflammation from the surrounding parts to the joint, i. 246; Mayo's case of injury to the ancle, followed by absorption of the cartilages, and effusion and organization of lymph between the ends of the bones, i. 246; process of bony anchylosis, i. 246; the most important form of bony anchylosis, i. 246; Cruveilhier's case of bony anchylosis of the right condyle of the lower jaw, i. 247; other kinds of anchylosis, i. 247; treatment of the soft or ligamento-fibrous anchylosis, i. 247; Velpeau on the treatment of complete anchylosis, i. 247; Barton's operation of cutting out a wedge-shaped piece of bone, i. 247; also performed by Gibson, i. 247; operation for the establishment of a false joint, i. 247; Velpeau favourable to this proceeeding, i. 248; performed by Barton and Rodgers with success, i. 248; the operation of breaking through the anchylosis, i. 248; condemned by Velpeau, i. 248; Amussat's case, i. 248; Velpeau on the consequences of the adhesion of the knee-pan to the condyles of the femur, i. 248; Louvrier's apparatus for the rupture of the anchylosis, i. 248; Velpeau's objections to the use of that apparatus, i. 249; *hysterical affections of the joints*, i. 249; Brodie on the symptoms of hysterical affections of the joints, i. 249; Tyrrell on the diagnosis between inflammation and hysterical affection of the joints, i. 249; Bell's case of hysterical affection of the hip-joint, i. 249; Coulson's case, i. 250; Coulson on the symptoms of this disorder, i. 250; Goodlad's objection to the term "hysterical" being applied to these affections, i. 250; South on the constitutional treatment of the disorder, i. 250; Brodie and Goodlad on the local applications, i. 250; *inflammation of the hip-joint (coxalgia)*, i. 250; the three stages of the disease, i. 250; symptoms of acute inflammation of the hip-joint, i. 251; Key on the greater frequency of chronic than of acute inflammation of, i. 251; symptoms when suppuration takes place, i. 251; symptoms of first stage of chronic inflammation of the hip-joint, i. 251; Brodie on ulceration of the cartilage, the primary affection in diseased hip, i. 252, 261; Key's opinion that the ulceration of the cartilages is proceeded by inflammation of the ligamentum teres, i. 252, 261; South on the pain on the inside of the knee in hip-disease, i. 252; Bell and Coulson's explanation of that symptom, i. 252; symptoms of the second stage of chronic inflammation of the hip-joint, i. 252; Astley Cooper on the second stage of hip disease, i. 252; Key on the symptoms which indicate the special part of the joint affected, i. 253; symptoms of the third stage, i. 253; Fricke's method of examining the length of the limb during the progress of the disease, i. 253; Astley Cooper and Coulson on the bursting of abscesses of the hip-joint, i. 253; Dr. Mackenzie and Scott's cases of abscesses of the hip-joint, i. 254; Brodie on the difference between hip disease from ulceration of the cartilage, and that from scrofulous deposit in the cancellous structures of the bones, i. 254; shortening and lengthening of the diseased limb, i. 255; Hunter on these symptoms, i. 255; Cline and Lawrence on these symptoms, i. 256; the shortening only apparent, i. 256; Rust and Fricke's explanation incorrect, i. 256; South on the shortening of the limb, i. 256; the lengthening of the limb may be either seeming or real, i. 256; explanation of the lengthening of the limb by Petit, Camper, Valsalva, Monro, Van der Haar, de Haen, Vermandois, Schwenke, Callisen, Plenck, Portal, Ficker, Duverney, Clossius, Boyer, Falconer, Rust, Langenbeck, Richter, Schreger, Larrey, Chelius, Fricke, Brodie, and Crowther, i. 257; Weber's experiments show that the head of the thigh-bone is retained in the socket by atmospheric pressure, i. 257; these experiments of great importance in reference to diseases of the hip-joint, i. 257; South's explanation of the lengthening of the limb, i. 257; Astley Cooper on the lengthening of the limb from effusion into the joint, i. 258; Lawrence on the lengthening of the limb, i. 258; dislocation of the head of the thigh-bone, i. 258; Nester, Van der Haar, Berdot, Schreger, and Textor on the dislocation of the head of the thigh-bone downwards and inwards, i. 258; Hoffman's case of separation of the head of the femur, and its removal by the surgeon, i. 258; South on the appearances after death in hip disease, i. 258; Earle on dislocation into the ischiatic notch, i. 258; Boyer, Brodie, and Coulson on dislocation into the foramen ovale, i. 259; Ducros jun. on dislocation forwards on the share-bone, i. 259; the formation of a new socket, i. 259; Samuel Cooper on the substance which fills up the acetabulum, i. 259; diagnosis of coxalgia from congenital luxation of the thigh, shortening of the extremity from recession and twisting of the hip-bone, nervous sciatica, and malum coxæ senile, i. 259; coxalgia cannot well be confounded with phlegmasia alba dolens, psoas abscess, or primitive dislocation of the thigh, i. 260; may be confounded with fracture of the neck of the thigh-bone under certain circumstances, i. 260; Bell on the pain in hip disease, i. 260; South on the sympathetic pain in the hip from disordered bowels, i. 260; South, Smith, Wernherr, Astley Cooper, and Charles Bell on the morbus coxæ senilis, i. 260; Coulson on the diagnosis between hip disease in the third stage, and psoas abscess, i. 261; post-mortem appearances, i. 261; post-mortem appearances in William Adams' case, i. 262; etiology of hip-joint disease, i. 262; Fricke on the distinction between coxalgy and coxarthrocacy, i. 262; prognosis always unfavourable, i. 262; treatment, i. 262; in the first stage of acute coxalgia, i. 262; Coulson on salt-water bathing in hip-disease, i. 263; treatment of chronic coxalgia, i. 263; Nicolai and Klein recommend the use of the apparatus for fractured neck of the femur, i. 263; Physick on the treatment of coxalgia, i. 263; Scott's plan of treatment, i. 263; Lawrence's observations on the plan of treatment advocated by Scott, i. 264; has been employed by Fricke with advantage, i. 264; treatment of the second stage, i. 265; application of the actual cautery. i. 265; Rust objects to the use of issues, i. 265; approved of by South, i. 265; the actual cautery or burning cylinders preferable in all cases where the limb is much lengthened, the muscles relaxed, and where there is great swelling from collection of fluid, i. 265; Volpi has not found benefit from the actual cautery, when the first symptoms of disease occurred in the knee. and not at the hip-joint, i. 265; Brodie on the influence of the primary irritation of the issue, and on the maintaining it by repeated applications of caustic potash or sulphate of copper, i. 265; approved of by South, i. 266; Duval's local steam-bathing apparatus, i. 266; Brodie on the use of a seton in the groin, i. 266; results of the treatment, and management of convalescence, i. 266; Rust and Brodie on warm bathing, i. 267; Fritz, Rust, and Jaeger on the mercurial treatment, i. 267; Brodie on the importance of rest and position, i. 267; general treatment in the first two stages of coxalgy, i. 267; Jaeger, Rust, Dieffenbach. and Frank on the general treatment of coxalgy, i. 267; Fricke's plan, i. 267; treatment of the consecutive dislocation, i. 268; reduction of the dislocation frequently not successful, i. 268; views of Petit, Callisen, and Jaeger on the reduction of consecutive dislocation, i. 268; cases by Berdot, Hagen, Ficker, Thilenius, Mozilewsky, Schneider, B. Heine, F. Humbert, M. N. Jacquier, Textor. Volpi, Schreger, von Winter, Harless, Fricke, and J. Heine, i. 268; treatment of suppuration, i. 269; the abscesses to be freely opened, i. 269; Ford, Wend, Van der Haar, Rust, Brodie, and Jaeger on the treatment of these abscesses, i. 269; Sabatier and Ficker advise their being opened with caustic, i. 269; Larrey, with the red-hot trocar, i. 269; Rust, with the actual cautery, i 269; Rust advises passing a seton through the joint, i. 269; Brodie and Jaeger recommend free incisions in opening these abscesses, i. 269; Brodie and South on the management of abscesses at the hip, i. 269; subsequent treatment, i. 269; resection of the carious head of the thigh-bone, i. 269; excision of the head of the femur recommended by Jaeger, Kirkland, Richter, and Vermandois, i. 270; performed by White and Hewson, i. 270; Kerr and Baffos exarticulated the thigh-bone, i. 270; Charles Bell's proposition, i. 270; Barry's case of accidental reduction of the dislocation, i. 270; *inflammation of the shoulder-joint — omalgia*, i. 270; three stages of the disease, i. 270; symptoms and results, i. 270; dislocation of the head of the bone, i. 271; abscesses and caries of the bone, i. 271; post mortem appearances, i. 271; etiology, prognosis, and treatment, i. 271; *inflammation of the knee-joint* (*gonalgia*), i. 271; symptoms and progress, i. 271; difference between rheumatic and scrofulous white swelling of the knee-joint, i. 271; post-mortem appearances, i. 272; South and Brodie on the diagnostic symptoms of the diseases of the knee, i. 272; Brodie on ulceration of the cartilages, i. 273; Rainey on a peculiar degeneration of the cartilage in disease of, i. 273; Brodie on scrofulous disease in the cancellated structure of the bones of, i. 274; progress of caries, i. 274; *white swelling*, i. 274; application of the term, i. 274; the disease very frequent in Great Britain, but rare in Italy, Vienna, and many other parts of Germany, i. 275; Russell and Gotz on the appearances of white swelling on dissection, i. 275; Nicolai on the symptoms and progress of white swelling. i. 275; Nicolai on the anatomy of white swelling, i. 276; prognosis and treatment, i. 277; *inflammation in the joints of the vertebræ* (Pott's disease), i. 277; locality and symptoms of the disease, i. 277; curving of the spine, i. 277; Pott on the symptoms and progress of the disease, i. 277; caries of the vertebræ, the cause of curvature of the spine, i. 278; connection of the disease with lumbar and psoas abscess, i. 278; Lawrence and Brodie on the curvature from caries, i. 278; Pott on the so-called palsy of the limbs, i. 278; Brodie on the occurrence of suppuration in caries of the vertebræ, i. 278; Brodie on the disappearance of psoas abscess, and its appearance elsewhere, i. 278; Brodie on the pain in vertebral caries, i. 279; Brodie on the extent of the curvature in dorsal caries, i. 279; post-mortem appearances, i. 279; Brodie, Key, and Lawrence on the pathology of spinal caries, i. 280; Brodie on chronic inflammation of the vertebræ, with ulceration of the intervertebral cartilage, i. 280; causes of the disease, i. 280; diagnosis and prognosis, i. 280; diagnostic signs of the disease, according to Copland, Wenzel, Stiebel, Melker, and South, i. 281; South, Lawrence, and Brodie on the diagnosis between curvature of the spine from caries and that from rickets, i 281; treatment of the disease, i. 282; Brodie on the applicability of issues in this disease, i. 283; Astley Cooper, Lawrence, and Brodie on the manner in which the disease is cured by anchylosis, i. 283; symptoms of the disease in the cervical vertebræ, i. 284; Brodie and Astley Cooper on vertebral caries in the neck, i. 284; Brodie on abscess connected with vertebral caries in the neck, i. 284; post-mortem appearances, i. 285; symptoms and progress of the disease in the sacro-iliac synchondrosis, i. 285.

JOINTS, WOUNDS OF, i. 489; symptoms, i. 489; probing the wound objectionable, i. 489; danger of joint-wounds, i. 489; Hunter on the suppurative inflammation of wounded joints, i. 489: Astley Cooper on wounds of joints, and their results, i. 489; treatment, i. 489; Astley Cooper's treatment of wounded joints by a fine suture, i. 490; Abernethy's practice, i. 490; commended by South, i. 490; treatment of the accompanying inflammation, i. 490; of the suppuration, i. 491; cases requiring amputation, i. 491; gunshot-wounds of the joints, i. 491.

JOINTS, UNNATURAL, i. 587; definition, i. 587: John Hunter on the formation of false joints, i. 588; causes. i. 588; Brodie, Gibson. and Amesbury on the formation of a false joint, with a fibro-ligamentous capsule, and a lining membrane, i. 588; false joints most frequent in the upper arm, i. 588; Amesbury. South, and Astley Cooper on the causes of the non-union of fractured bones, i. 588; Macmurdo's case of false joint of the humerus, i. 589; treatment of false joints, i. 589; John Hunter on the treatment of false joints, i. 589; rubbing the ends of the broken bone together, i. 589; Celsus, Boyer, and South on rubbing the ends of the broken bone together, i. 589; Cittadini's case, i. 589; pressure, i. 589; application of pressure, i. 590; application of blisters, caustic potash. and tincture of iodine, i. 590; South on the application of pressure in false joints, i. 590; South objects to external irritation, i. 590; application of strong caustics to destroy the cartilaginous surfaces on the ends of the bones, by Ollenroth, Cline jun., Hewson, Weilinger, and Kirkhide, i. 590; Mayer and Hulse's plans of treatment, i. 590; White, Cline, Lehmann, and Barton's cases of cure of ununited fractures, i. 591; Cline jun. and Hewson's cases of cure by the application of caustic potash to the broken ends of the bones, i. 591; the operation of sawing off the cartilaginous ends of the fractured bone, i. 591; Dupuytren, Pigné, and Brodie on this operation, i. 591; Guy de Chauliac's account of this operation, as practised by the Arabian physicians, i. 592; Charles White and Lawrence on sawing off the ends of the broken bone, i. 592; Green's operation on an ununited fracture of the femur, i. 592; South's remarks on this case, i. 592; the introduction of a seton, i. 593; Weinhold, Oppenheim, and Jobert on the introduction of the seton, i. 593; danger attending the use of the seton in oblique fracture, i. 593; Physick on the use of the seton, i. 593; Fricke and Cittadini's operations for sawing off the ends of the fractured bones successful, i. 594.

JOINTS, cartilaginous bodies in, ii. 705; amputation through, ii. 931.

JONAS on puncturing the distended intestine after the operation for strangulated hernia, ii. 391.

JONES' experiments on the ligature of arteries, i. 303: on the application of the ligature, ii. 218; on the effects produced by the ligature on the arterial coats, ii. 219.

JONES, H. BENCE, on the formation of urinary calculi, ii. 513; on the phosphatic diathesis, ii. 522; on the treatment of uric acid gravel, ii. 534, 535; on the treatment of the oxalic diathesis, ii. 537; on the treatment of the phosphatic diathesis, ii. 538.

JONES', Dr. WHARTON, description of the phenomena of inflammation under the microscope, i. 29; on exudation, i. 33; on the process of union by adhesion, i. 290; on healing by the second intention, or granulation, i. 294.

JÖRG's apparatus for keeping the head straight in wry-neck, ii. 154; on the influence of spinal curvature on the transverse diameter of the pelvis, ii. 158.

JOSSE's apparatus for fracture of the neck of the femur, i. 569.

JOUBERT on the acarus scabiei, i. 636.

JOUREL's case of puncturing the womb in retroversion, ii. 144.

JUDD on hydriodate of potash in syphilis, i. 669.

JUNOD's apparatus to cause derivation of the blood, i. 868.

Kaltenbrunner on the formation of new vessels, i. 292.

Kayser on the statistics of the Cæsarian operation, ii. 438.

Keate's operation for stone in infants, ii. 569; case of chimney-sweep's cancer on the cheek, ii. 816.

Keckely's apparatus for fractured clavicle, i. 551.

Keith's, Dr., case of vesico-vaginal fistula cured by a calculus in the bladder acting as a valve to prevent the discharge of the urine, i. 759.

Kellie's, Dr., remarkable case of exposure to cold, i. 126.

Kendrick on the treatment of hæmorrhage consecutive to the extraction of a tooth, i. 769.

Kennedy's case of gunshot wound on the right side of the thyroid cartilage, i. 438; case of bands in the vagina, ii. 376.

Kentish's plan of treatment of burns, i. 113; mode of application of stimulants, i. 113; disapproval of frequent dressings, i. 113.

Kern on the application of caustic for the radical cure of hernia, ii. 24; on ligature of the protruded omentum at the abdominal ring for the radical cure of rupture, ii. 24; operation for stone in women, ii. 620; mode of amputating at the knee with the flap-cut, ii. 943.

Ker's case of procidentia uteri treated with the secale cornutum, ii. 113.

Kerr's mode of amputating at the hip-joint by the circular cut, ii. 934.

Kerst's mode of operating in excision of the ancle-joint, ii. 983.

Key on ulceration in ligamentous fibre, i. 208; on the conditions under which ulceration of the cartilages takes place, i. 229; on the absorption of cartilage by a new membrane produced by inflammation of the synovial membrane, i. 229; on the progress of ulceration in cartilage, i. 230; accordance of his views with those of Wilson, i. 232; on the changes in the synovial membrane, when suppuration is the result of a wound in it, i. 232; they induce ulcerative absorption of the articular cartilages, i. 232; on the formation of an adventitious membrane in joints, in cases of necrosis of the long bones, when it causes inflammation and absorption of the cartilages, i. 234; this is a repairing process preparatory to anchylosis, i. 234; on ulceration of cartilage, an action altogether different to absorption, i. 235; on the process of ulceration generally, i. 235; on the process by which ulceration of cartilage is effected, i. 235; it leads to the formation of abscess, i. 235; describes the degeneration of cartilage into a fibrous structure as a third mode of ulceration, i. 236; on the two forms of disease in bone, resulting in absorption of the cartilage, i. 238; the chronic form is of a strumous nature, i. 238; the acute form differs from the chronic in the comparative suddenness of the attack, and in the appearance which the bone presents, i. 238; on the period at which the inflammation in the joint-end of the bones is likely to occur, i. 239; on the removal of the articular cartilages in old age, i. 241; on the formation of a vascular membrane in joints, as a preliminary to anchylosis, i. 242; on the greater frequency of chronic than of acute inflammation of the hip-joint, i. 251; is of opinion that the ulceration of the cartilages in hip disease is preceded by inflammation of the ligamentum teres, i. 252, 261; on the symptoms which indicate the special part of the joint affected, i. 253; on the pathology of spinal caries, i. 280; on the propriety of active, general, and local depletion in strangulated omental hernia, prior to the operation, ii. 14; on the reduction *en masse*, ii. 16; advises the unfolding the omentum before cutting it off, ii. 41; on abscess in the sac occasionally reproducing the symptoms of strangulation, ii. 42; on the operation of dilating the abdominal ring, without opening the sac, ii. 43; views with regard to this operation, ii. 44; on the signs indicative of gangrene of the intestine, ii. 45; case of gangrenous intestine, in which a fetid smell was perceptible before the sac was opened, ii. 45; on suppuration of the sac, ii. 49; case of sloughing of the intestine after its return into the abdomen, ii. 49; on the occurrence of gangrene in the intestine some days after the operation, in persons of an enfeebled constitution, ii. 50; on the fatal termination of cases after the operation, when preceded by great depression, ii. 51; case of strangulated inguinal rupture, the testicle being at the external ring, ii. 62; on the seat of strangulation in femoral rupture, ii. 72; on the operation for femoral rupture, ii. 74; on the post-mortem appearances in a case in which he tied the subclavian twelve years previously, ii. 248; mode of operating for stone in the bladder. ii. 584; on suppurative inflammation of the cellular tissue surrounding the bladder, the most frequent cause of death after lithotomy, ii. 609; on the advantages and applicability of lithotrity, ii. 625; on lithotrity with reference to the size of the calculus, ii. 626; on the applicability of lithotrity or lithotomy, according to the age of the calculous patient, ii. 626; on the requisite condition of the bladder for the operation of lithotrity, ii. 627; on irritability of the bladder, ii. 627; case of sarcomatous scrotum, ii. 805; case of exarticulation of metatarsal bones, with the diseased bones of the tarsus, ii. 953.

Kidneys, wounds of, i. 480; nature, symptoms, and treatment, i. 480; stone in, ii. 539.

Kilian on the application of the suture in vesico-vaginal fistula, i. 755.

King on artificial anus at the umbilicus, connected with the diverticulum ilei, i. 722; on ligature of the innominata, ii. 246; on the extirpation of the ovary, ii. 487; case of extirpation of the ovary, ii. 489.

Kirby on the effects of the scorpion sting, i. 351; cases in which severe symptoms followed the use of the ligature in piles, ii. 303; on tracheotomy in croup, ii. 399.

Kirkhide on the use of caustic to destroy the ends of the broken bone in false joints, i. 590.

Kirkland, Dr., advises to let lumbar or psoas abscess break of itself, i. 190; recommends the resection of the carious head of the femur in hip-disease, i. 270; on the arrest of hæmorrhage by nature, i. 297.

Kleberg on congenital dislocation of the knee, i. 806.

Klein recommends the use of the apparatus for fractured neck of the femur in the treatment of hip disease, i. 263; on the exhibition of prussic acid in tetanus, i. 381; apparatus for fracture of the neck of the femur, i. 570; on the treatment of prolapse of the rectum, ii. 133; on sounding the bladder, ii. 550; operation for the division of the middle branches of the facial nerve, and of the infra-orbitar nerve, ii. 884: operation for dividing the facial nerve, ii. 885; operation for dividing the inferior maxillary nerve, ii. 885; operation for destroying the trunk of the facial nerve at its exit from the stylo-mastoid foramen, ii. 885; the operation performed in two cases without a permanent cure, ii. 886; considers it to be entirely free from danger, ii. 886; objections to the upper flap in partial amputation of the foot, ii. 948.

Klimatis on the solution of the chloride of lime in the treatment of foul, gangrenous, or torpid ulcers, i. 615.

Kluge's plan of treating lymph abscesses, i. 91; torsion-apparatus, i. 310; apparatus for fracture of the lower jaw, i. 529; bandage for fractured clavicle, i. 551; method of replacement of the dislocated femur, i. 798, 800.

Knee-cap, fracture of, i. 576; dislocation of, i. 804.

Knee-joint, dislocation of, i. 805; curvatures of, ii. 172; exarticulation of the leg at, ii. 942; excision of, ii. 981.

Köhler on the torsion of bony vessels, i. 311; experiments on the excision of joints, ii. 969.

Kolletscha on the formation of new vessels, i. 292.

Koppenstædter's apparatus for fractured clavicle, i. 551; fracture-bed, i. 571.

Kramer's case of excision of the heads of metatarsal bones, ii. 985.

Krause on the existence of itch without eruption, i. 635; on the microscopic characters of medullary fungus, ii. 719.

Krimer on the removal of the edges of the cleft in staphyloraphy, i. 604; plan for bringing the edges of the cleft together, i. 605; operation when the cleft is very large and complicated, i. 606; on the operation of amputation at the hip-joint, ii. 933.

Kuh's operation for varicocele, ii. 297.

Kuhl's case of ligature of both carotids, ii. 233.

Labarraque on the solution of the chloride of lime in the treatment of foul, gangrenous, or torpid ulcers, i. 615.

Labat's case of bands in the vagina, ii. 376; modification of the Indian method of rhinoplasty, ii. 837.

Labia, abscess of, i. 160; enlargement of, ii. 665.

Lacerated and contused wounds, i. 333. *See* Wounds.

Lacroix on the nervous symptoms attending sudden retroversion of the womb, ii. 140.

Laennec on the membrane of the fistulous passages, i. 92; on the physical characters of dropsy of the pericardium, ii. 479; on the division of tumors, ii. 648.

Lafond, Jalade, on the reduction of congenital dislocation of the femur, i. 803; pad with a reservoir for caustic, used for radical cure of hernia, ii. 23.

Lallemand on iodine in hard swellings of the testicles, i. 669; on the appearances presented on post-mortem examination, some time after the cure of artificial anus, i. 720; on cauterization as a means of cure in vesico-vaginal fistula, i. 752; on the application of sutures in vesico-vaginal fistula, i. 755; caustic-holder for stricture of the urethra, ii. 370; on the treatment of complete retention of urine in stricture, ii. 427; on the operation for cutting into the urethra in the perinæum, ii. 428; on the retention of the catheter in the urethra, ii. 432.

Lampe's artery-compressor, i. 299.

Langenbeck's opinion on the lymph-swelling, i. 48; on the treatment of fistulous passages by ligature, i. 93; treatment of long fistulæ in the breast, i 151; condemned by South, i. 152; on the lengthening of the limb in hip-disease, i 257; artery-compressor, i. 299; on hydrophobia as caused by a qualitative alteration of the blood by the poison, i. 372; employs trepanning in injuries of the head only when secondary symptoms of irritation and pressure require it, i. 412 on the treatment of fractured patella, i 578; on the nature of strangulation in rupture, ii. 11; on increased pressure and the supine posture in the radical cure for hernia, ii. 23; on ligature of the hernial sac for its radical cure, ii. 24; on excision of the prolapsed and scirrhous womb, ii. 115; on ligature of the external iliac, ii. 261; operation for division of the inner fold of the prepuce, ii. 347; on the ligature of the carotid, prior to the extirpation of the parotid, ii. 783; operation for amputation of the penis, ii. 802; case of extirpation of the cancerous womb, ii. 823, 825; operation for the division or excision of the facial nerve at the stylomastoid foramen, ii. 886; operation for flap amputations, ii. 892; mode of amputating the thigh with two flaps, ii. 908; mode of amputating at the hip-joint with the flap-cut with a single flap, ii. 936; objections to the upper flap in partial amputation of the foot, ii. 948; mode of operating in exarticulation of the metatarsal bone of the great toe, ii. 952; in amputation at the shoulder-joint, ii. 958; mode of operating in exarticulation of the metacarpal bones of the ring and little fingers, ii. 964.

Langius on mortification from spurred rye, i. 61.

Langlet's case of a ball remaining in the brain for eighteen months, i. 400.

Langstaff's case of a madman who swallowed a silver spoon, ii. 389; on tumors of nerves of stumps, ii. 765.

Larrey's, Baron, plan of treating burns, i. 112; on the effects of frost-bite, i. 127; observations on the effects of too suddenly warming a frozen or benumbed limb, i. 130; on the lengthening of the limb in hip-disease, i. 257; on opening abscesses at the hip with the red-hot trocar, i. 269; on the union of the nerves of a stump in loops, i. 330; on amputation in tetanus, i. 380; on the removal of foreign bodies in injuries of the brain, i. 398; case of loss of memory after concussion, i. 409; on the subsequent effects of the closure of the opening in the skull after trephining, i. 425; case of excision of a portion of a rib for the removal of a ball, i. 446; practice in wounded intestine, i. 464; on the treatment for compound fractures, i. 512; on the immoveable apparatus in fractured ribs, i. 547; on inversion of the foot in fracture of the neck of the femur, i. 565; apparatus for fracture of the neck of the femur, i. 569; on the internal opening of rectal fistula, i. 726; moxa of rotten phosphorescent wood, ii. 882; case of amputation through the head of the tibia, ii. 917; mode of amputating at the hip-joint with two flaps, ii. 937; at the shoulder-joint, ii. 957; operation for the excision of the head of the humerus, when fractured by a musket-shot, ii. 960; case of excision of part of the hand, ii. 965; on excision of joints, ii. 969.

Larrey's, H., cases of regular shaped gun-shot wounds, i. 338.

Laryngotomy, ii. 399.

Laryngo-tracheotomy, ii. 403.

Larynx, fracture of the cartilages of, ii. 550; wounds of, i. 432; foreign bodies in, ii. 394.

Laserre's apparatus for fractured clavicle, i. 551.

Latour's case of accumulation of blood in the womb, and rupture of the organ, i. 483.

Latta on tapping lumbar or psoas abscess with a trocar, and passing a seton through the abscess afterwards, i. 189; his practice condemned by South, i. 189.

Lawrence's cases of malignant pustule, i. 64; on sloughing phagedena, i. 69; on incisions in pseudo-erysipelas, i. 108; opposed to the treatment of erysipelas by moderate compression, i. 108; case of alarming hæmorrhage from puncturing an immature tonsillar abscess, i. 142; on the hæmorrhage following the extirpation of the tonsils, i. 146; on gonorrhea benigna and virulenta, i. 161; on gonorrhea virulenta, i. 162; on lumbar abscess generally connected with carious vertebræ, i. 186; supports Abernethy's treatment of lumbar abscess, i. 190; on the diagnosis of fluctuation in synovial inflammation, i. 216; on hydrarthrus or hydrops articuli, i. 216; on the pulpy degeneration of the synovial membrane, i. 217; on ulceration of cartilage as an original affection of the joints, i. 229; case of rapid ulceration of cartilage, i. 234; on the necrosis of long bones as a cause of inflammation and absorption of cartilage, i. 234; on the lengthening and shortening of the affected limb in hip-disease, i. 256, 258; observations on the plan of treatment advocated by Scott in hip-disease, i. 264; on curvature of the spine from caries, i. 278; on the pathology of spinal caries, i. 280; on the diagnosis between curvature of the spine from caries and that from rickets, i. 281; on the manner in which the disease is cured by anchylosis, i. 283; objection to the term "inflammation" in reference to union by adhesion, i. 291; on the after-management of the ligature on arteries, i. 306; on the absorption of poisonous matter in dissection wounds, i. 349; details of Dr. Pett's case, i. 350; on the fatal effects of the stings of bees and wasps, i. 351; case of hydrophobia, i. 366; on the communication of hydrophobia from one human being to another, or from man to beasts, i. 366; on the peculiar delirium of hydrophobia, i. 370; on a costive state of the system preceding tetanus, i. 378; on the proximate cause of tetanus, i. 378; case of pistol-shot wound of the brain, i. 398; on puncturing the dura mater to evacuate effused blood, i. 407; on bleeding from the tongue from bites made during a fit, i. 431; cases of partial or complete dislocation of the spine, i. 535; case of complete dislocation of the fourth from the fifth cervical vertebra, i. 535; occurrence of vertebral dislocation specially in the neck, i. 536; case of fracture of the os calcis, i. 585; sawing off the ends of the broken bone in false joints, i. 592; on the period at which the operation for hare-lip should be performed, i. 596; on the use of scissors with knife-edges in the operation, i. 597; on the sutures in the operation for hare-lip, i. 597; on the progress of syphilis from one part of the body to another, i. 642; on the progress of ulceration in a syphilitic sore, i. 643; on the five kinds of syphilitic sores, i. 643: on the four kinds of syphilitic eruptions, i. 648; on the exhibition of mercury in cases of chancre, and on the rarity of the occurrence of secondary symptoms when mercury has been used, i. 656; on the extent to which the use of mercury may be pushed, i. 656; case of a syphilitic child infecting the nurse, i. 673; on syphilitic iritis and ulceration about the anus in infants, i. 674; on the possibility of infection from secondary syphilis, i. 675; on the combined effects of mercury and syphilis in the production of the mercurial disease, i. 676; definition of caries, i. 682; on the treatment of caries, i. 686; case of necrosis from irritation, i. 688; on the terms "necrosis" and "exfoliation," i. 691; on salivary calculi, i 715; on the appearances presented on post-mortem examination some time after the cure of artificial anus, i. 721; on Dupuytren's operation for artificial anus, i. 722; on dislocations from muscular action, i. 763; on the double hernial sac, ii. 4; on the statistics of rupture, ii. 6; on the nature of strangulation, ii. 11; on the reduction *en masse*, ii. 16; objections to operations for the radical cure of hernia, ii. 29; modification of Petit's operation, ii. 44; ascribes the fatal result after the operation for strangulated hernia, not to the exposure of the parts to air and light, but to the protracted constriction to which they have been subjected, ii. 45; recommends op [illegible] the stricture from within, ii. 46; on the statistics of wounds of the epigastric or obturator artery in operations for femoral rupture, ii. 78; case of fatal hemorrhage from a wounded branch of the epigastric, ii. 79; case of successful operation for strangulated umbilical rupture during pregnancy, ii. 82; case of rupture of the recti abdominis, ii. 84; on thyroid rupture, ii. 88; on the symptoms of internal strangulation, ii. 94; on the *bruit de soufflet*, ii. 200; on the effects produced by the ligature on the arterial coats, ii. 219; on Brasdor's operation, ii. 230; on the peculiar noise heard in an aneurismal varix, ii. 270; on the application of the ligature in teleangiectasy, ii. 282; on the spongy excrescence of the rectum, ii. 335; on stricture of the rectum, ii. 336; on the use of bougies in stricture of the rectum, ii. 339; on the use of bougies armed with caustic potash in stricture of the urethra, ii. 368; on the use of the armed bougie, ii. 371; case of the neck of a wine-bottle in the rectum, ii. 394; cases of worms and larvæ discharged from the urethra, ii. 417; on catheterism in inflammation of the prostate, ii. 420; on chronic enlargement of the prostate, ii. 422; on the treatment of enlarged prostate, ii. 424; on the treatment of retention of urine from enlarged prostate, and on catheterism in such cases, ii. 425; on the transition between new or accidental productions and changes of structure, and degenerations of organs, ii. 646; case of very large fatty tumor, ii. 691; case of cellular membranous tumors, ii. 711; case of amputation just above the ancle, ii. 922.

Lawrence, John, on the immoveable apparatus for fractures, i. 504.

Lawrie, Dr., on the part played by the dead bone in necrosis in the process of reproduction, i. 694; on the cause of the difficulty experienced in reducing dislocations of the thumb from the metacarpal bone, i. 795; on the use of the actual cautery in prolapsus uteri, ii. 113; on the results of amputation, ii. 905; objections to amputation below the knee, ii. 922.

Leacock's case of fatal phrenic rupture, ii. 92.

Leber's artery-compressor, i. 299; on the stanching the bleeding from an intercostal artery, i. 447.

Leblanc on incision of the hernial sac, etc., for its radical cure, ii. 24; on dilatation of the stricture in strangulated hernia without cutting, ii. 38.

LECAT on dilatation of the stricture in strangulated hernia without cutting, ii. 38; mode of operating for stone, ii. 594.

LEE, DR. ROBERT, on inflammation of the femoral and iliac veins, an occasional cause of phlegmasia dolens, i. 80.

LEE, STAFFORD, on the statistics of the operations for the extirpation of the ovary, ii. 490.

Leeches, application of, ii. 864.

Leg, fracture of the bones of, i. 580; artificial, ii. 846; amputation through, ii. 915; exarticulation of, at the knee, ii. 942.

LEHMANN's case of cure of ununited fracture, i. 591; operation for varicocele, ii. 297.

LEMAIRE on the solution of the chloride of lime in the treatment of foul, gangrenous, or torpid ulcers. i. 615.

LEMBERT's practice in wounded intestine, i. 464; approved of, i. 469; Dupuytren's modification of, i. 469.

LENOIR on the causes of varicocele, ii. 296; on dropsy of the bursæ in the sole of the foot, ii. 460; mode of amputating through the leg in its lower third, ii. 917; mode of amputating at the hip-joint with the flap-cut with the single flap, ii. 936.

LENTIN on neuralgia of the heel, treated by deep incisions, ii. 887.

LEROY D'ETIOLLES on the statistics of the operations for cancer, ii. 768.

LEUCORRHEA distinguished from gonorrhea, i. 159, 160; Dr. Locock on leucorrhea, i. 160; characters of the secretion, i. 160; Locock and Jewel on the distinguishing signs between leucorrhea and gonorrhea, i. 160.

LESENBERG's plan for bringing the edges of the cleft together in staphyloraphy, i. 605.

LEWIN'S, DR., experiments on colchicum as a cause of an increased production of uric acid in the urine, i. 626.

LEWIS on the treatment of hydrocele by punctures, ii. 500.

LIBER on the torsion of arteries, i. 308.

LIEBER on torsion of arteries, ii. 227.

LIEUTAUD on incision of the hernial sac, etc., for its radical cure, ii. 24.

Ligaments, Inflammation of. *See* Inflammation of the Joints.

LIGHTFOOT's case of prolapse of the bladder, in which he performed the operation of episioraphy, ii. 129.

LIMBOURG'S, DE, case of wound of the head with a ramrod, i. 429.

Lingual artery, ligature of, ii. 238.

LINNÆUS on the acarus scabiei, i. 636.

Lips, cancer of, ii. 773.

LIORDAT's emporte-pièce, i. 723.

LISFRANC's plan of treating burns with a solution of the chlorate of lime, i. 112; on the use of the stethoscope in the diagnosis of fractures, i. 498; case of fracture of the os calcis, i. 585; on the solution of the chloride of lime in the treatment of foul, gangrenous, or torpid ulcers, i. 615; case of reduction of an old dislocation of the elbow-joint, i. 790; on the cause of the difficulty experienced in reducing dislocations of the thumb from the metacarpal bone, i. 794; on the relative frequency of aneurism in the sexes, ii. 203; on the relative frequency of aneurism in the arteries, ii. 203; on the ligature of a diseased artery, without opening the sheath, ii. 222; on the section of the scalenus anticus in ligature of the subclavian, ii. 242; on ligature of the external iliac, ii. 261; vestibular cut in lithotomy in women, ii. 620; operation for cancer of the corpora cavernosa, ii. 803; operation for scirrhous cervix uteri, ii. 822; case of fatal hæmorrhage from leech-bites, ii. 866; mode of amputating at the hip-joint with two flaps, ii. 938; in exarticulation of the metatarsal bones, ii. 950; at the shoulder-joint, ii. 956; modification of the operation when performed prior to the age of fifteen, ii. 960; mode of operating in exarticulation of the hand at the wrist, ii. 963; on exarticulation of the middle and ring fingers, ii. 966; flap-operation of the fingers, ii. 966.

LISTON's account of the hospital gangrene in University College Hospital in 1841, i. 68; on the formation of new vessels, i. 292; adhesive plaster, i. 325; mode of operating in staphyloraphy, i. 605; on epulis, i. 702; case of speedy reduction of a dislocated femur, i. 765; on the mode of reducing dislocation of the thumb from the metacarpal bone, i. 795; on the causes of splay-foot, ii. 186; on compression in the treatment of aneurism, ii. 213; case of ligature of the subclavian above the clavicle, ii. 243; on spontaneous aneurism of the brachial, ii. 251; on ligature of the arteries of the fore-arm, ii. 251; on the peculiar noise heard in an aneurismal varix, ii. 270; case of aneurismal varix in the femoral vein and artery, ii. 270; on the seat of stricture in the rectum, ii. 336; case of foreign body in the bronchus, in which tracheotomy was performed, and the foreign body extracted with forceps, ii. 402; case of partial solution of a stone in the bladder, ii. 553; on the dilatation of the female urethra, ii. 556; mode of operating for stone in the bladder, ii. 584; operation for stone in women, ii. 618; on the incontinence of urine consequent on lithotomy in women, ii. 621; on the breaking or bending of lithotritic instruments in the bladder, ii. 623; on the cases in which lithotrity should be performed, and on those in which lithotomy should be preferred, ii. 628; case of a small brass ring encircling the penis, ii. 630; case of sarcomatous tumor of the scrotum, ii. 711; on tumors of nerves, ii. 765; case of sarcomatous scrotum, ii. 806; operation for raising a sunken nose, ii. 844; on the use of the saw in amputations, ii. 893; preference of the flap operation, and objections to the circular operation, ii. 902; mode of amputating through the thigh by the flap operation, ii. 909; account of eighteen amputations through the thigh, ii. 910; mode of amputating through the leg with two flaps, ii. 920; statistics of amputation through the leg, ii. 922; statistics of amputation through the upper arm, ii. 925; cases of amputation through the fore-arm, ii. 927; on amputation through the metacarpal bones, ii. 930; mode of amputating at the hip-joint with two flaps, ii. 940; case of amputation at the shoulder-joint, ii. 961; mode of operating in excision of the lower jaw, ii. 993; mode of operating in resection of the upper jaw, ii. 998; on the prospect of ultimate success in this operation in cases of malignant disease, ii. 1001; case of resection of the scapula, ii. 1002; employment of ether by inhalation prior to the performance of important surgical operations, ii. 1008.

Literature of surgery, i. 9.

Lithotrity, ii. 557.

Lithotomy, ii. 568; recto-vesical lithotomy, ii. 612; lithotomy in the female, ii. 616.

Lithectasy, ii. 642.

LITTLE, Dr., on the diagnosis between club-foot and the deformity of the tarsus caused by rickets, ii. 176; case of amputation of the thigh, with the flap behind, ii. 909.

LITTRE's mode of operating in ovarian dropsy, ii. 487.

LIZARS on the large operation for ovarian dropsy, ii. 489; the first to recommend the entire removal of the upper jaw, ii. 996; description of the proposed operation, ii. 996; case in which he attempted to perform the operation, but failed on account of the hæmorrhage which ensued, ii. 996; cases in which he performed the operation, ii. 996.

LIVER, WOUNDS OF, i. 478; symptoms, i. 478; danger of such wounds, i. 478; Astley Cooper on stabs of the liver, i. 478; South on rupture of the liver, i. 478; treatment, i. 478; *wounds of the gall bladder*, i. 479; consequences of such wounds, i. 479; symptoms of effusion of bile into the cavity of the abdomen, i. 479; Hœring and Emmert's experiments on the injection of bile into the cavity of the peritoneum, i. 479; Dupuytren's experiments, i. 479; case of wounded gall-bladder quoted by Gooch, i. 479.

LOCHER on vesicles on the spleen in hydrophobia in dogs, i. 371.

LOCOCK, Dr., on leucorrhea, i. 160; characters of the secretion, i. 160; on the distinguishing signs between leucorrhea and gonorrhea, i. 160; on pudendal discharges in females during dentition, i. 161; case of bands in the vagina from previous difficult labour, ii. 376; case of spontaneous rupture of the ovarian cyst, ii. 491.

LODE on two kinds of curvature of the hand, ii. 192.

LOEFFLER on puncturing the distended intestine after the operation for strangulated hernia, ii. 391.

LONNES', IMBERT DE, case of sarcomatous tumour of the scrotum, ii. 711.

LORCH on the effects of torsion, i. 311.

Lordosis, ii. 158.

LOTTERY on stanching the bleeding from an intercostal artery, i. 447.

LOUIS on the rotation of the foot outwards in fracture of the neck of the femur, i. 564; on the reduction *en masse*, ii. 16; case of a foreign body remaining a long while in the windpipe, ii. 396; mode of amputating by the circular incision, ii. 890.

LOUVRIER's apparatus for the rupture of anchylosis, i. 248; Velpeau's objections to its use, i. 249; on the more general application of the trephine, i. 413; on the friction-cure in syphilis, i. 663.

LOWE on puncturing the distended intestine after the operation for strangulated hernia, ii. 391.

LUGOL on iodine in scrofula, i. 623; formulæ for the exhibition of iodine, i. 623; dispute with Alibert on the acarus scabiei, i. 636.

LUKE on the use of the ligature in rectal fistula, and on the mode of operating, i. 732; on the dilatation of a strangulated rupture on coughing, ii. 13; on reduction *en masse*, ii. 17; on the signs indicative of reduction *en masse*, ii. 18; on the operation required when reduction *en masse* has occurred, ii. 19; description of the operation for dividing the stricture external to the sac, ii. 47; on the diagnosis of the seat of stricture, ii. 47; on incision of the sac, or on partial division of its neck in several places, when the stricture is caused by it, ii. 48; case of resection of the scapula, ii. 1002.

LUMBAR MUSCLES, INFLAMMATION OF; LUMBAGO, PSOITIS:—seat of the inflammation, i. 185; symptoms, i. 185; formation of abscess, i. 185; general symptoms of suppuration not present if the abscess be not large, i. 185; this disease not what is usually called "lumbago," but psoas or lumbar abscess, i. 185; Astley Cooper on the symptoms of psoas abscess, i. 185; Pearson on the symptoms preceding and accompanying the formation of the abscess, i. 186; causes, i. 186; English surgeons generally consider disease of the vertebræ to be the cause, i. 186; Pott on the diseased condition of the spine in this complaint, i. 186; Astley Cooper on the origin of psoas or lumbar abscess in inflammation of the spine and intervertebral substance, i. 186; Abernethy, Lawrence, and Dupuytren on lumbar abscess generally connected with carious vertebræ, i. 186; South on the origin of the disease from external violence, its seat then being in the spine, i. 187; South on the distinctive characters of psoas abscess from femoral hernia, i. 187; John Pearson on the situation of the external abscess, i. 187; Samuel Cooper's notice of Ramsden's case of lumbar abscess, i. 187; treatment of inflammation of the lumbar muscles, i. 187; South on the insidious progress of the disease, i. 188; abortive treatment of lumbar abscess, i. 188; opening the abscess, i. 188; Dupuytren on the changes that sometimes take place in the abscess, i. 188; Astley Cooper remarks that the abscess must be allowed to take its course, i. 188; this opinion controverted by South, i. 188; Cline and Abernethy's experiments to cause the absorption of the pus, i. 188; South on issues in the treatment of lumbar or psoas abscess, i. 188; difference of opinion as to propriety of waiting the self-evacuation of the abscess, or of puncturing and emptying it, either entirely or partially, i. 189; Deckers, Benjamin Bell, and Crowther on tapping the abscess with a trocar, i. 189; Latta recommends the use of a seton in addition, i. 189; this latter practice condemned by South, who prefers opening the abscess with a lancet, i. 189; Abernethy's plan of treatment, i. 189; Astley Cooper and Lawrence support Abernethy's views, i. 190; Kirkland advises to let the abscess break of itself, i. 190; John Pearson prefers making a small aperture, and treating the ulcer in a very gentle manner, i. 190; Dupuytren leaves the abscess to nature, i. 190; South's plan of treatment, i. 190; treatment to be pursued after the abscess is opened, i. 191; Pearson and Astley Cooper on the treatment of the sinuous cavities resulting from the abscess by injections, i. 191; Dupuytren recommends cauterization or weak injections of nitrate of silver, or nitric acid, i. 191; treatment of the abscess, if inflammation supervene, after it has been opened, i. 191; Abernethy on the symptoms of the supervening inflammation, i. 191; Pearson mentions that the larger arteries sometimes ulcerate into the abscess, i. 191; M'Dowell mentions a case in which ulceration took place in a portion of the ileum adhering to the cyst of the abscess, i. 191.

Lungs, wounds of, i. 440, 449. *See* Wounds of the Chest.

Lupus, or herpes exedens, i. 628.

Lynn's performance of the Taliacotian operation, ii. 831.

Macaulay's case of phrenic rupture, depending on malformation of the diaphragm, ii. 92.

McClellan, Dr. on the cause of bronchocele, ii. 655; on bronchocele as a variety of scrofula, ii. 656; case of resection of the scapula and clavicle together, ii. 1004.

McCormac, Dr., on careful traction of the skin in prolapse of the rectum, ii. 136.

M'Dowall, Dr., on the large operation for ovarian dropsy, ii. 489.

M'Dowell mentions a case in which ulceration took place in a portion of the ileum adhering to the cyst of a lumbar abscess, i. 191.

Macgill's case of ligature of both carotids, ii. 232.

McGrigor, Sir James, on the period of the accession of tetanus after the receipt of the injury, i. 377.

Mackenzie's, Dr., case of abscesses of the hip-joint i. 254.

Mackintosh, Dr., on an epidemic vaginal catarrh, i. 161.

McLaughlan's, Dr., case of a large plug of wood in the rectum, ii. 392.

Macmurdo's case of rupture of a vessel in the penis during coition, i. 157; case of secondary hæmorrhage in cut throat, i. 434; case of false joint of the humerus, i. 589; case of aneurismal varix between the internal jugular vein and carotid artery, ii. 268; case of cellular membranous tumor, ii. 711.

Macrae's case of a foreign body in the bronchus, ii. 401.

McSweeny, Dr., on the silk-worm gut ligature, i. 307.

Magendie's experiment on the communicability of hydrophobia from man to man, and from man to beasts, i. 366; case of hydrophobic patient biting another person, i. 369; on the formation of urinary calculi, ii. 513; on hairy gravel, ii. 530; on the treatment to be adopted when air enters a vein during an operation, ii. 856; on the cause of death from entrance of air into a vein, ii. 856; on the injection of warm water into the veins in hydrophobia, ii. 877.

Maiden's case of penetrating wound of the chest, i. 440.

Maingault's mode of amputating at the knee with the flap cut, ii. 943; mode of operating in partial amputation of the foot, ii. 948.

Malagodi's case of excision of a portion of the ischiatic nerve in the region of the knee-joint, ii. 887.

Malgaigne on the local treatment of fractured ribs. i. 547; on the frequency of dislocation in the different joints, i. 764; on the primitive direction of dislocation of the humerus, i. 782; case of reduction of an old dislocation of the elbow, i. 790; on the cause of the difficulty experienced in reducing the dislocation of the thumb from the metacarpal bone, i. 795; on the seat of strangulation in ruptures, ii. 11; case of resection of the fibula, ii. 1007.

Mammary, internal, ligature of, ii. 249.

Mandt on the chemical and microscopic characters of pus, i. 35; on the pus-globules, i. 40; on the presence of globules in the serum, i. 43.

Manec on the introduction of a piece of bougie into an ossified artery after amputation, i. 304; on ligature of the innominata, ii. 247; mode of amputating at the hip-joint by the flap-cut with a single flap, ii. 937.

Manovy's case of division of the posterior tibial nerve, ii. 887.

Marcet, Dr., on the premonitory pains of hydrophobia, i. 371; case of knife-swallowing, ii. 398.

Marchetti's case of swine's tail in the rectum, ii. 393.

Marjolin on excision of the prolapsed and scirrhous womb, ii. 115.

Marochetti on the presence of pustules under the tongue after the bite of a mad animal, i. 375; plan of treatment prophylactic of hydrophobia, i. 375; views objected to by Watson. i. 376.

Marshall on the application of flour in cases of burns, i. 116.

Martin on the causes of club-foot, ii. 176.

Martineau's cases of very small urinary calculi, ii. 547; operation for stone in the bladder, ii. 587.

Martinière's, De la, case of a foreign body in the windpipe, ii. 395.

Mauchart on incision and scarifications of the hernial sac, for its radical cure, ii. 24.

Maunoir on the effects produced by the ligature on the arterial coats, ii. 219; on the ligature of the spermatic artery in varicocele, ii. 297; treatment of bronchocele by puncture and irritating injections, and by seton, ii. 663; on simple serous cysts of the neck, ii. 695; on the chemical constituents of the brain-like substance in medullary fungus, ii. 719; on ligature of the spermatic artery in sarcocele, ii. 811.

Maunsell's, Dr., description of noma, i. 62; on the suppuration of mumps, i. 149; on the communication of syphilis to the fœtus in the womb, i. 673; on the symptoms of syphilis in infants, i. 673; on its treatment, i. 674.

Mauriceau on the operation for the treatment of lacerated perineum, i. 611; on the application of the sutures, i. 611.

Maxillary sinus, disease of, ii. 739; bone, lower, fracture of, i. 528; excision of, ii. 986; upper, resection of, ii. 994; fracture of, i. 527; artery, external, ligature of, ii. 239.

Mayo describes the occasional occurrence of pus-globules in healthy blood, i. 41; case of injury to the ligaments of the knee, i. 206; describes three distinct forms of ulceration of joint-cartilages, i. 228; case of injury to the ancle, followed by absorption of the cartilages, and effusion and organization of lymph between the ends of the bones, i. 246; on the progress of caries, i. 682; on inflammation as the cause of caries, i. 684; on the treatment of caries, i. 686; on the application of caustic in varix, ii. 292; on hæmatocele, ii. 445; on dropsy of the bursæ mucosæ, ii. 458; on the formation of bursæ from pressure, ii. 458; case of large calculus, ii. 546; on tumours of nerves in stumps, ii. 765.

Mayor's treatment of fractured clavicle, i. 551; treatment of false joints, i. 590; on the sutures in the operation for hare-lip, i. 598; operation for the radical cure of hernia, ii. 26; on extirpation of bronchocele by ligature, ii. 664; on ligature of the neck of the womb, ii. 822; on amputation of the phalanges with the tachytome, ii. 931.

Mead, Dr., on viper's fat as a local remedy in viper's bite, i. 354; case of the bite of a rattlesnake, i. 354; experiments on viper-poison, i. 355; on the protraction of the period of incubation in hydrophobia, i. 366; on the increase of muscular strength in hydrophobia, i. 370

Meckel on the vessels of cartilage, i. 226; on the three kinds of union of divided parts—quick union, by adhesion, and by granulation, i. 288; on the causes of cerebral rupture, ii. 99; case of cure of cerebral rupture, ii. 99; on the influence of spinal curvature on the transverse diameter of the pelvis, ii. 158; on the division of tumours, ii. 648; opinion that melanosis is the same as medullary fungus, ii. 723.

Medin on the stanching the bleeding from an intercostal artery, i. 448.

Meding's experiments on incomplete fracture, i. 497; on the production of callus, i. 501.

Medullary Fungus, ii. 715; characters, ii. 715; symptoms and situation, ii. 717; medullary fungus of the testicle, ii. 717; symptoms and termination, ii. 717; of medullary fungus of bone, ii. 718; Astley Cooper on medullary fungus of bone, ii. 718; appearances of the parts on dissection, ii. 718; chemical examination of the brainlike substance, ii. 719; Hecht, Maunoir, and Müller on the chemical constituents of the brain-like substance, ii. 719; Krause on the microscopic characters of medullary fungus, ii. 719; Gluge on the nature of, ii. 719; medullary fungus occasionally encysted, ii. 720; characters of the brain-like substance in medullary fungus of the testicle, ii. 720; characters of medullary fungus, ii. 721; Allan Burns and von Walther on the difference between fungus hæmatodes and sarcoma medullare, ii. 721; Abernethy on fungus hæmatodes, ii. 721 Müller on the applicability of the term "medullary fungus" to the different forms of soft cancer, ii. 722; Vogel on the essential element of medullary fungus, ii. 722; Bradley, Jaeger, and Vogel on the blood fungus, ii. 722; Meckel's opinion that melanosis is the same as medullary fungus, ii. 723; this opinion only partially correct, ii. 723; diagnosis between medullary fungus and scirrhus, ii. 724; Breschet's different kinds of carcinoma, merely different degrees of development of medullary fungus, ii. 725; Abernethy's sarcoma tuberculatum considered by Meckel to be medullary fungus, ii. 725; this opinion incorrect, ii. 725; etiology of medullary fungus, ii. 725; diathesis fungosa, ii. 725; seat and mode of formation of medullary fungus, ii. 725; treatment of the disease almost entirely ineffective, ii. 726; early ablation of the part or amputation of the limb affords the only chance of cure, ii. 726; the disease generally returns sooner or later, ii. 726.

Meig's plan of treatment in ingrowing of the nail by a compress and linen-roller, i. 200.

Melier's apparatus for dislocation of the clavicle forwards, i. 779.

Melker's diagnostic sign for vertebral caries, i. 281.

Melle's case of dislocation of the scapular end of the clavicle downwards, i. 780.

Mendaga on the hydrarg. cyan. in syphilis, i. 662.

Mende on the seeming retroversion of the womb at the latter periods of pregnancy, ii. 140.

Menzel on the operation for the treatment of lacerated perineum, i. 611.

Mercier's opinions on the changes which the substance of the bone undergoes in advanced age, i. 497; on inversion of the foot in fracture of the neck of the femur, i. 565; on the characters of horns, ii. 671; on the treatment to be adopted when air enters a vein during an operation, ii. 856.

Mercurial disease, i. 675.

Merrem, Dr., on wounds of the uterus, as predisposing to rupture in subsequent labours, i. 484; explanation of this fact, i. 484.

Méry on incision of the hernial sac and the introduction of lint tents for its radical cure, ii. 24.

Mesenteric and mesocolic ruptures, ii. 93.

Metacarpal bones, amputation through, ii. 927; exarticulation of, at the carpus, ii. 963; excision of, ii. 965.

Metacarpus, excision of the joints of, ii. 985.

Metastatic abscesses, i. 36.

Metatarsal bones, amputation through, ii. 927; exarticulation of, ii. 949; excision of, ii. 966; fracture of the bones of, i. 562.

Metatarsus, excision of the joints of, ii. 985.

Mettauer, Dr., on the operation of staphyloplasty by granulation, i. 600.

Meyer on the application of nitric acid to the scar of nerves, i. 330; apparatus for fracture of the neck of the femur, i. 569; case of strictured œsophagus communicating with the left bronchus, ii. 320; case of resection of the clavicle, ii. 1003.

Michaelis on the treatment of gonorrhea, i. 175; on the operation for the ingrowing of the nail, i. 200; on the division of the tendo Achillis in club-foot, ii. 182; on the doubtful character of the old cases in which the Cæsarian operation is reported to have been performed several times successfully on the same woman, ii. 438; case in which the operation was performed four times on the same woman, ii. 439; on the danger attending the effusion of the secretions from the wound into the belly, ii. 442; on the exhibition of opium, and on the necessity of keeping the bowels open after the operation, ii. 442; on the greater probability of success attending the repetition of the operation, than in the first instance, ii. 444.

Miescher on the ossification of arteries, i. 77; says no difference between permanent cartilage, and that which is to be converted into bone, i. 223; differs in opinion with W. Hunter respecting the fibrous structure of articular cartilage, i. 223; on the production of callus, i. 501; summary of views on the formation of the primary and secondary callus, i. 501; experiments to induce suppuration in compound fractures, i. 510; summary of experiments to ascertain the processes under which suppurating fractures are united, i. 516; on the granulations attending caries, i. 682; on the characters of caries, i. 683; on the seat of the various kinds of caries, i. 684; on the signs of exfoliation, i. 692; on the absorption of part of the dead bone in the process of exfoliation, i. 692; on the process of cicatrization after necrosis, i. 695.

Mirault's operation for the ligature of the tongue, ii. 779.

Möbus' case of vertebral aneurism, ii. 250.

Model's opinion that spurred rye does not cause gangrene in beasts, i. 61; disproved by Tessier, i. 61; Block's experiments on the subject, i. 61.

Mohrenheim's apparatus for fracture of the patella, i. 579.

Moj'sisovic's equilibrium plan in fracture of the femur, i. 574.

Möller's case of gangrene of the penis, from the constriction of a metal ring, i. 487.

Monnier's, Le, operation of staphyloraphy, i. 603.

Monro on the lengthening of the limb in hip-disease, i. 257; slippers for rupture of the tendo Achillis, i. 494; on the application of caustic for the radical cure of hernia, ii. 24; on the dilatation of the abdominal ring, the hernial sac being unopened, ii. 43; cases of half-pence in the œsophagus, ii. 382; case of a foreign body in a sac behind the œsophagus at its origin, ii. 382.

Montain on the operation for the treatment of lacerated perineum, i. 611; on the application of the sutures, i. 611.

Monteiro's case of ligature of the aorta, ii. 255.

Montgomery, Dr., on the origin of scirrhus uteri in the ova Nabothi, ii. 817; case of cancer uteri, ii. 818.

Morand on the arrest of hæmorrhage by nature, i. 297; on the extirpation of the ovary, ii. 487; mode of amputating at the shoulder-joint with the circular cut, ii 958.

Moreau's case of excision of a joint, ii. 969 on the excision of joints, ii. 969; statistics of cases, ii. 970; mode of operating in excision of the head of the humerus, ii 974; in excision of the elbow-joint, ii 975; on the division of the ulnar nerve in excision of the elbow-joint, ii. 975 mode of operating in excision of the knee-joint, ii. 981; on the mode of union after the operation, ii. 982; mode of operating in excision of the ancle-joint, ii. 983.

Morère's case of abscess of the womb, i. 484.

Morgagni on the causes of varicocele, ii 296.

Morgan's opinions relative to the formation of pus, i. 35; on the reduction of the dislocated femur by placing the foot between the thighs, and making extension and rotation, i. 801; case of a pouch formed at the mouth of the tunica vaginalis, ii. 4.

Morris', Dr., case of injurious effects produced by the inhalation of ether, ii. 1008.

Mortification:—divided by Chelius into the hot and cold, i. 53; Travers' objection to the terms mortification and sphacelus, i. 53; definition of mortification, i. 53; symptoms, i. 54; Travers' acute gangrene, i. 54; destruction of the mortified parts occurs either as dry, moist, or hospital gangrene, i. 54; South on vesications filled with a bluish or bluish-black fluid in cases of severe bruise, or when the bandages in cases of fracture are too tight, i. 55; causes of mortification, i. 55; Brodie on sudden loss of blood, a cause of mortification, i. 55; Travers on deep and extensive effusion, and on injuries of nerves, as causes of mortification, i. 55; South's case of mortification of the lower extremity from effusion of blood causing distension of the limb, i. 55; mortification in cases of aneurism caused by distension from effusion, i. 56; mortification in cases of simple fracture, the principal artery of the limb being uninjured, i. 56; South's cases of mortification after fever, i. 56; senile gangrene, i. 57; distinction between senile gangrene consequent on injury, and that resulting from constitutional causes, i. 57; Travers' chronic gangrene, i. 58; causes of dry gangrene, i. 59; South's case of dry gangrene consequent on abdominal typhus, i. 59; Dupuytren on arteritis, a cause of dry gangrene, i. 59, 75; South's case of dry gangrene from organic disease of the heart, i. 59; Brodie's case of dry gangrene from inflammation of the principal artery and vein of a limb, i. 59; Brodie on the cause of the distinction between dry and moist gangrene, i. 59; gangrene from arterial inflammation a comparatively rare disease, i. 59; this statement denied by Cruveilhier and Dupuytren, i. 59; South's case of arteritis without gangrene, i. 60; Solly's case of gangrene, i. 60; mortification from continued pressure, i. 60; mortification from the use of the cock-spurred rye, i. 60; Thomson's account of this form of the disease, i. 61; Sigebert and Bayle's remarks, i. 61; the disease first noticed by Dodard, afterwards by Saviard, Noel, Langius, Quassoud, Bossau, and Duhamel, i. 61; Elliotson's case of gangrene of the leg after the use of ergot, the arteries of the limb being also ossified, i. 61;

Model's opinion that spurred rye does not cause gangrene in beasts. i. 61; disproved by Tessier, i. 61; Block's experiments on the subject, i. 61; Dr. C. Woolaston's cases of gangrene, i. 61; mortification of the cheek, called noma by Vogel, i. 61; a rare and generally fatal disease, i. 61; description of noma by Drs. Evanson and Maunsell, i. 62; the term, cancrum oris, incorrectly applied to noma, i. 62; cancrum oris, a form of mortification commencing with ulceration, generally first in the gums, and thence spreading to the lips and cheeks, i. 62; described by Dr. Cumming, i. 62; South's case of noma in the adult, i. 62; mortification, a consequence of contagious influence, results in malignant pustule, or hospital gangrene, i. 63; malignant pustule, its causes and symptoms, i. 63; contagious from beasts to man, but not from man to man, i. 63; Elliotson on glanders in the human subject, i. 64; Lawrence's cases of malignant pustule, i. 64; Beer's and Delpech's cases, i. 65; Turchetti's cases of malignant pustule, described by him as anthrax, i. 66; Dr. Wagner's cases of malignant pustule, produced by contact, and by eating the flesh of diseased animals, i. 66; Dr. Bourgeois' observations on malignant pustule, i. 67; hospital gangrene, i. 68; description of the disease, i. 68; local and general symptoms, i. 68; Liston's account of the hospital gangrene in University College Hospital in 1841, i. 68; Arnott's cases of hospital gangrene at the Middlesex Hospital, i. 69; the disease exceedingly rare in the London hospitals, i. 69; Lawrence on sloughing phagedena, i. 69; Welbank on sloughing phagedena, i. 70; this disease regarded by S. Cooper as resembling hospital gangrene, i. 70; denied by South, i. 70; South on the sloughing state of stumps from want of power, i. 70; the characteristic of hospital gangrene, i. 70; the cause of hospital gangrene is the operation of a peculiar contagious matter, i. 70; it is always a very dangerous complication of wounds and sores, i. 70; treatment of gangrene, i. 94; when connected with active inflammation, and inflammatory fever, moderate antiphlogistic treatment to be employed, i. 94; if caused by the constriction of unyielding aponeuroses, they must be divided, i. 94; when connected with general debility, tonics and mineral acids indicated, i. 94; local treatment of gangrene, i. 94; if there be active inflammation, soothing poultices: if the part be free from pain, and shrivelled, stimulant applications required, i. 95: remedies which prevent the influence of the gangrenous juices, i. 95; their action aided by scarifications in the gangrenous parts, i. 95; these latter must not penetrate into the living parts, i. 95; scarifications are dangerous in gangrena senilis, i. 95; amputation not applicable in gangrene depending on an internal cause still in operation, i. 95; applicable after the line of demarcation has formed, or in gangrene from external violence, even while still proceeding, i. 95; South's opinion that amputation should never be performed while the gangrene is in progress, i. 95; treatment of senile gangrene, i. 96; when resulting from an injury, soothing or dry aromatic applications, or leeching, if the inflammation be active, i. 96; Dupuytren employed the antiphlogistic plan of treatment in plethoric subjects, i. 96; when from constitutional causes, tonics and opium necessary, i. 96; treatment of gangrene from pressure, i. 96; from the use of spurred rye, i. 96; Thomson and S. Cooper's cases, i. 97; treatment of malignant pustule, i. 97; local treatment by cutting out the pustule, and cauterizing the wound, i. 97; if the pustule not deep, but the slough much spread, deep scarifications and the application of caustic recommended, i. 97; employment of constitutional treatment, i. 97; treatment of hospital gangrene, i. 97; emetics advised by Pouteau and Dussausoy, i. 97; washing the sore with vinegar or solution of arsenic in the commencement of the disease, i. 97; the entire surface to be touched with nitrate of silver, i. 98; the free application of the actual cautery most effectual, i. 98; constitutional treatment should be employed at the same time, i. 98; gangrenous destruction of parts from burns, i. 110; treatment of mortification caused by burns, i. 112; cold wet sufficient to induce mortification, if continued sufficiently long to reduce the natural heat below a certain standard, i. 126; gangrene the result of too suddenly warming a frozen limb, i. 129; treatment of a frozen part in which mortification is threatened, from its having been too hastily warmed, i. 130; when mortification has taken place, it must be treated in the usual manner, i. 130; treatment of gangrenous chilblains, i. 131; gangrene of the testicle a rare termination of inflammation, i. 179; causes and treatment of mortification in compound fractures, i. 509; South on mortification in compound fractures, and its treatment, local and general, i. 511; sloughing of the omentum in strangulated hernia, ii. 41; gangrene of the intestine in strangulated hernia, ii. 42.

Morton on the inhalation of ether prior to the extraction of teeth, ii. 1007.

Moscati on the extirpation of the tonsils by cutting, i. 145.

Mosely's, Dr., case of scorpion sting, i. 351; on the chigoe, i. 352.

Mothe on the primitive direction of dislocation of the humerus, i. 782.

Mott on the treatment of fistula of the rectal sheath, i. 733; on the operation for tying the innominata, ii. 245; operation for the ligature of the common iliac, ii. 256; mode of amputating at the hip-joint with two flaps, ii. 938; case of excision of part of the side of the lower jaw, without the condyle, ii. 988; mode of operating in excision of the lower jaw with the condyles, ii. 989; on the previous ligature of the carotid artery, ii. 990; case of exarticulation of one side of the lower jaw, ii. 993; case of resection of the clavicle, ii. 1004.

Motte, La, on the operation for the treatment of lacerated perineum, i. 611; on the application of the sutures, i. 611.

Mouffet on the acarus scabiei, i. 636.

Mouth, narrowing and closure of, ii. 315; foreign bodies in the, ii. 380.

Moxas, application of, ii. 882.

Mozilewsky's case of reduction of the consecutive dislocation in hip-disease, i. 268.

Mülder's mode of operating in excision of the knee-joint, ii. 981; in excision of the ancle-joint, ii. 983.

Müller on inflammation, i. 22; comparison of the effects of heat and cold on the body, i. 126; on the vessels of cartilage, i. 227; on the causes of necrosis, and on the process of regeneration, i. 687; on the production of new bone after necrosis, i. 694; on the division of tumors, ii. 648; on enchondron, ii. 674; on the varieties of fatty tumors, ii. 691; on the chemical constituents of the brain-like substance in medullary fungus, ii. 719; on the applicability of the term "medullary fungus" to the different forms of soft cancer, ii. 722; on the four several kinds of carcinoma, ii. 757; on carcinoma simplex et fibrosum, ii. 757; on carcinoma reticulare, ii. 757; on carcinoma alveolare, ii. 758; on carcinoma fasciculatum, ii. 758; proposal to separate the fibrous part of the blood prior to transfusion, ii. 880.

Münzenthaler's mode of operating in exarticulation of the metatarsal bones, ii. 950.

Murray's, Dr., case of ligature of the aorta, ii. 254.

Mursinna on the more general application of the trephine, i. 413; on the treatment of fractures of the neck of the femur, i. 570; on the operation for the treatment of lacerated perineum, i. 611; on the primitive direction of dislocation of the humerus, i. 782.

Muscles, lacerations of, i. 494.

Mussey's, Dr., case of ligature of both carotids, ii. 232; on the treatment to be adopted when air enters a vein during an operation, ii. 856; case of resection of the scapula and clavicle together, ii. 1004.

Mütter's plastic operations for the relief of deformities from burns, i. 125; on the period at which the operation for hare-lip should be performed, i. 596; on the advantage of operating early in hare-lip and cleft-palate, i. 599; on the treatment of cleft-palate after the operation for hare-lip, i. 599; on the use of obturators in cleft-palate, i. 600; on the operation of staphyloplasty by granulation, i. 600; successful operation in a case of loss of substance in the hard palate from chronic mercurial disease, i. 601.

Mynors' mode of amputating by the circular incision, ii. 890.

Naëgele on the use of the suture in vesico-vaginal fistula, i. 753, 755.

Naëgele's, jun., case of womb at the eighth month of pregnancy, ruptured by external violence, i. 485.

Nannoni on amputation at the shoulder-joint, with the circular cut, ii. 958.

Nasal bones, fracture of, i. 526.

Nasse's case of lymph-swelling from external injury, i. 48; on injecting a solution of neutralized nitrate of mercury into a cold abscess, i. 90.

Naumburg on the causes of club-foot, ii. 176.

Neck, wounds of the, i. 431; nature of the wounds, i. 431; Astley Cooper on wounds of the throat, i. 431; deep penetrating wounds, with injury of the large vessels, i. 431; Travers' case of suicidal wound of the lingual or facial artery near its origin, with unsuccessful ligature of the common carotid, i. 432; injuries of the pneumo-gastric nerve, i. 432; of the recurrent nerve, i. 432; of the laryngeal nerve, i. 432; Dupuy's experiments on the division of both pneumogastric nerves, i. 432; injury of the sympathetic or phrenic nerve, or of the spinal marrow, i. 432; wound of the windpipe, i. 432; loss of voice in large wounds of the windpipe, i. 432; Hennen on emphysema in wounds of the windpipe, i. 432; treatment of transverse wounds of the windpipe, i. 433; Fricke on the treatment of severe wounds of the neck, i. 433; South on position in the treatment of wounds of the windpipe, i. 433; South on the treatment of such wounds, i. 433; treatment of the general symptoms accompanying such wounds, i. 433; subsequent treatment, i. 434; South on the treatment of such wounds, when there is much inflammation, i. 434; South's case of fistulous wound between the thyroid and cricoid cartilages, i. 434; Astley Cooper's case of fistulous opening in the thyroid cartilage, i. 434; South on secondary hæmorrhage in cut throat, i. 434; Macmurdo's case, i. 434; stabs of the windpipe, i. 434; bruised wounds of the larynx and windpipe, i. 435; shot-wounds with loss of substance, i. 435; South on the management of the resulting fistula, i. 435; wounds of the gullet, i. 435; signs and treatment, i. 435; the œsophagus-tube, i. 435; Astley Cooper's objection to the use of the tube, i. 435; Stark's case, i. 435; Dr. Ryan's case, i. 436; Hennen's case of wound of the larynx and œsophagus, i. 437; healing of wounds of the gullet, i. 437; stabs of the gullet, i. 437; deep wounds at the back of the neck, i. 437; Hennen's case of severe nervous symptoms following gunshot wound of the throat, i. 437; Kennedy's case of gunshot-wound of the right side of the thyroid cartilage, i. 438.

NECROSIS, i. 687; definition and divisions, i. 687; situation, i. 687; causes, i. 687; Müller on the causes of necrosis, and on the process of regeneration, i. 687; Bromfield and Lawrence's cases of necrosis from irritation, i. 688; symptoms, i. 688; John Hunter on the ossific inflammation preceding necrosis, i. 688; diagnosis, i. 689; distinguishing characters of caries and necrosis, i. 689; separation of the dead bone as sequestrum, i. 690; the processes of exfoliation, and of compensation for the dead bone, i. 690; the reproduction of bone not dependent on the periosteum, i. 691; Lawrence on the terms "necrosis" and "exfoliation," i. 691; Weinhold's objection to the term "exfoliation," i. 691; John Hunter on the process of exfoliation, i. 691; John Hunter and Miescher on the signs of exfoliation, i. 692; Miescher and South on the absorption of part of the dead bone in the process of exfoliation, i. 692, 693; Troja on the incipient production of new bone after necrosis, i. 693; Weinhold on the cloacæ in necrosis, i. 694; Müller on the production of new bone, i. 694; Lawrie on the part played by the dead bone in the process of reproduction, i. 694; Miescher on the process of cicatrization, i. 695; John Hunter on the species of exfoliation, i. 695; prognosis, i. 696; cases of necrosis indirectly affecting the joints, and requiring amputation, i. 696; Porter's case of wound of the popliteal artery by a sequestrum, i. 696; treatment, i. 697; separation and removal of the sequestrum, i. 697; treatment in cases of necrosis of old standing, i. 698; cases in which amputation is indicated, i. 698.

NÉGRIER on fresh walnut leaves, and their decoction in scrofula, i. 624.

NELKEN'S Dr., instrument for applying the ligature in rectal fistula, i. 732.

NEMBER on the exhibition of purgatives in strangulated hernia, ii. 32.

Nephrotomy, ii. 542.

Nerves, division of, in neuralgia, ii. 883.

NESTER on the dislocation of the head of the thigh-bone downwards and inwards in hip-disease, i. 258.

Neuralgia, division of nerves in, ii. 883.

NEVERMANN on the stanching the bleeding from an intercostal artery, i. 448; mode of operating, i. 448; treatment of lacerated perineum, by cauterizing with unslaked lime, and afterwards by position, i. 612; statistics of tracheotomy in laryngitis and tracheitis, ii. 399.

NICOLAI recommends the use of the apparatus for fractured neck of the femur in the treatment of hip disease, i. 263; on the symptoms and progress of white swelling, i. 275; on the anatomy of white swelling, i. 276; apparatus for fracture of the neck of the femur, i. 570.

NIEL on gold and its preparations in primary and secondary syphilis, i. 669.

Nipples, inflammation and fissure of. *See* Inflammation of the Breast.

NOEL on mortification from spurred rye, i. 61; on the operation for the treatment of lacerated perineum, i. 611; on the application of the sutures, i. 611.

Noma. *See* Mortification.

Nose, double, ii. 851; nose-making, ii. 830.

Nostrils, growing together and narrowing of, ii. 313; foreign bodies in the, ii. 380.

NUCK on ligature of the hernial sac for its radical cure, ii. 24; on the diverticulum of the peritoneum in the female, ii. 65.

Nymphæ, abscess of, i. 160.

NYSTEN on the cause of death from the entrance of air into a vein, ii. 856.

O'BEIRNE, Dr., on the fatal character of tetanus, i. 380; on the introduction of a thick elastic tube through the rectum into the sigmoid flexure of the colon in strangulated hernia, ii. 32; case of simple serous cysts of the neck, ii. 695.

O'BRYEN'S case of displacement of the heart, ii. 96.

O'CALLAGHAN'S, Dr., case of the lodgment of a foreign body in the frontal sinuses, i. 395.

Occipital artery, ligature of, ii. 239.

Œsophagotomy, ii. 385.

Œsophagus, wounds of, i. 435; stricture of, ii. 317; foreign bodies in the, ii. 381.

OESTERLEN'S observations on the re-breaking a badly-united fracture, i. 525; apparatus for re-breaking the bone, i. 525.

O'FERRALL'S, Dr., case of sarcomatous scrotum, ii. 807.

Ogle's case of puncturing the dura mater to remove the effused blood, i. 407.

Olecranon, fracture of, i. 560.

Oliver's case of fatal hæmorrhage from leech-bites, ii. 866.

Ollenroth on the use of caustic to destroy the ends of broken bone in false joints, i. 590; modes of operating in ovarian dropsy, ii. 487.

Ollivier on dislocation of the femur directly downwards, i. 796.

Omalgia, inflammation of the shoulder-joint, i. 270; three stages of the disease, i. 270; symptoms and results, i. 270; dislocation of the head of the bone, i. 271; abscesses and caries of the bone, i. 271; post-mortem appearances, i. 271; etiology, prognosis, and treatment, i. 271.

Onsenoort's, van, plan to prevent the needles tearing out after the operation for hare-lip, i. 599; on the treatment of hydrocele by seton, ii. 505; mode of amputating at the shoulder-joint, ii. 956.

Onychia maligna. *See* Ingrowing of the Nails.

Oppenheim on the introduction of the seton in false joints, i. 593; case of excision of the head of the femur, ii. 978.

Orchitis. *See* Inflammation of the Testicle.

Organic parts lost, restoration of:—history of nose-making, ii. 830; the Indian method, ii. 831; the Taliacotian operation, ii. 831; practised in England by Lynn, Sutcliffe, and Carpue, ii. 831; Graefe's modification of the Taliacotian operation, ii. 831; the second Indian method, ii. 832; South on the practice of plastic surgery in England, ii. 832; the several methods of reparation by a fold of skin from the neighbourhood, ii. 832; the value of plastic operations, ii. 833; rhinoplasty, and its occasional unfavourable results, ii. 833; subsequent changes in the new nose, ii. 834; the Indian operation preferable, ii. 834; Balfour, Braid, South, Barthélemy, and Regnault's cases of reunion of separated parts, ii. 835: *nose-making from the skin of the forehead*, ii. 836; the Indian method of rhinoplasty, ii. 836: directions for the operation, ii. 836; Graefe, Dieffenbach, Delpech, and Labat's modifications, ii. 836; subsequent symptoms and treatment, ii. 838; occurrence of gangrene, i. 838; removal of the stitches or pins, ii. 839; division of the fold of skin after complete union of the new nose, ii. 839; after-operations for perfecting the form of the nose, ii. 839; Graefe on the proper formation of the nostrils, ii. 839; defects of the wings of the nose, ii. 840; Dieffenbach's operation, ii. 840; deficiency of the side-edge as well as of the wing of the nose, ii. 840; the bridge of the nose sunken in, ii. 840; directions for the operation, ii. 840; Dieffenbach's modification of the operation, ii. 840; deficient columna narium, ii. 840; the operation, ii. 840; bottle-nose, and the operation to remedy the deformity, ii. 841; Gensoul's modification of the operation for deficient columna narium, ii. 841; Gensoul's case of chiloplasty, to remedy the deformity caused by gangrene, ii. 841; *forming the nose from the skin of the arm*, ii. 842; a more troublesome and uncertain operation than the Indian method, ii. 842; directions for the German operation, ii. 842; Benedict and Galenzowski's modifications of the operation, ii. 843; the Italian operation, as modified by Graefe, ii. 843; *raising a sunken nose*, ii. 843; Dieffenbach's operation, ii. 843; dressing and after-treatment, ii. 844; Liston and Fergusson's operations, ii. 844; Dieffenbach's operation for dropping in of the bridge of the nose, from destruction of part of the septum, ii. 845; the inhealing of metallic frames to remedy sunken noses, ii. 845; Tyrrell's case, ii. 845; Dieffenbach's operation to remedy the turning downwards of the tip of the nose, ii. 845; *mechanical compensation for lost parts*, ii. 846; *artificial legs*, ii. 846; the wooden leg, ii. 846; Paré, Ravaton, White, Addison, Wilson, Brünninghausen, Stark, Berrens, Heine, Graefe, Rühl, Palm, Dornbluth, Schmucker, Wals, Miles, and Serre's artificial legs, ii. 846; selection of an artificial leg, ii. 846; description of Ruhl's artificial leg, ii. 846; of Stark's artificial thigh, ii. 847; description and application of the wooden leg, ii. 847; Ruhl's wooden leg, ii. 847; *artificial foot*, ii. 847; *artificial hands*, ii. 848; Pliny, Götz von Berlichingen, Paré, Wilson, and Ballif's artificial hands, ii. 848; *artificial upper arms*, ii. 848; description of the apparatus, ii. 848; *artificial noses and ears*, ii. 848; *supply of lost portions of the hard palate*, ii. 849; use of obturators, ii. 849; *replacement of the teeth*, ii. 849; transplantation of teeth, ii. 849; application of artificial teeth, ii. 849.

—— **superfluity of**: — *supernumerary fingers and toes*, ii. 850; two different forms, ii. 850; treatment by operation, ii. 850; *supernumerary teeth*, ii. 850; causes, ii. 850; deformity caused by the irregular position of the teeth, ii. 850; treatment, ii. 850; *double nose*, ii. 851; either congenital or acquired, ii. 851; enormous degeneration of the nose, and its treatment by operation, ii. 851; treatment of cleft nose, ii. 851; Hey's case of immense tumour of the nose, ii. 851; Dalrymple on the nature and characters of these tumours, ii. 851.

Oribasius on the removal of the relaxed uvula by cutting, i. 147.

Orioli's case of fungus of the dura mater, treated by operation, ii. 689.

Orred's case of excision of a joint, ii. 968; mode of operating in excision of the head of the humerus, ii. 974.

Osborne, Dr., on the application of leeches to mucous surfaces, ii. 865; use of the polytome, ii. 868.

Os calcis, fracture of, i. 585; dislocation of, i. 812.

Os hyoides, fracture of, i. 530.

Osiander on the operation for the treatment of lacerated perineum, i. 611; on the extirpation of the cancerous neck of the womb, ii. 821.

O'Shaughnessy's case of removal of the upper jaw, ii. 999.

Osteosarcoma, ii, 677.

Osteosteatoma, ii. 677.

Otto on hydrocephalocele, ii. 98; on the causes of cerebral rupture, ii. 99.

Outrepont on the causes of congenital dislocation, i. 769.

Ovarian dropsy, ii. 486.

Ovaritis regarded by Ricord a complication of gonorrhea, i. 159.

Ovary, extirpation of, ii. 487.

Owen's case of viper-bite, i. 356; on the post-mortem appearances in Stevens' case of ligature of the internal iliac, ii. 257.

Paget's cases of diseased undescended testicle, ii. 814.

Paillaud on iodine in hard swellings of the testicle, i. 669.

Pailloux on the cause of the difficulty experienced in reducing dislocations of the thumb from the metacarpal bone, i. 795.

Pajola's mode of operating for stone, ii. 594.

Palate, hard, cleft in the, i. 599.

——, soft, cleft in the, i. 602.

Palletta on congenital dislocation of the hip, i. 769, 802; on the post-mortem appearances in, i. 803; case of congenital dislocation of the patella, i. 805; of extirpation of the womb, ii. 825.

Palmer on the torsion of arteries, i. 309.

Paracentesis thoracis, ii. 473; abdominis, ii. 482; uteri, ii. 495; of the intestines in tympanitis, ii. 495.

Paraphimosis, ii. 349.

Paré, Ambrose, used the ligature in cases of relaxed uvula, i. 147; on the operation for the treatment of ingrowing of the nail, i. 200; on the use of the ligature for wounded vessels, i. 320; bandage for fractured clavicle, i. 551; on the rotation of the foot outwards in fracture of the neck of the femur, i. 564; apparatus for fracture of the neck of the femur, i. 569; on the operation for lacerated perineum, i. 611; on congenital dislocation of the hip, i. 769; on ligature of the hernial sac for its radical cure, ii. 24; on the operation of dilating the abdominal ring, the hernial sac being unopened, ii. 43; on the causes of club-foot, ii. 176.

Parent on the hydrarg. cyan. in syphilis, i. 662.

Paris', Dr., case of a foreign body remaining a long while in the windpipe, ii. 396; on cancer of the scrotum, ii. 815.

Park's case of excision of a joint, ii. 969; mode of operating in excision of the knee-joint, ii. 981; on the mode of union after the operation, ii. 982.

Paronychia, i. 192.

Parotid duct, fistula of, i. 714.

Parotid gland, inflammation of, i. 148; abscess of, i. 148; cancer of, ii. 780; diseases of, ii. 780; extirpation of, ii. 782.

Patella, fracture of, i. 576; dislocation of, i. 804.

Pattison's case of teleangiectasy treated by acupuncture with red-hot needles, ii. 285.

Pauli on tattooing moles of the skin, ii. 286.

Paulus Ægineta on the removal of the relaxed uvula by cutting, i. 147; cauterized it with the aid of the staphylokauston, i. 147; on the application of the actual cautery for the radical cure of hernia, ii. 23; on aneurism, ii. 197.

Pearson's, Dr., opinion relative to the formation of pus, i. 35.

Pearson opposed to incisions in carbuncle, i. 138; on the symptoms preceding and accompanying the formation of a lumbar abscess, i. 186; on the situation of the external abscess, i. 187; prefers making a small aperture in lumbar abscess, and treating the ulcer in a gentle manner, i. 190; on the treatment of the sinuous cavities resulting from lumbar abscess, by injections, i. 191; states that the larger arteries sometimes ulcerate into the abscess, i. 191; on venereal paronychia, i. 194; on erethismus mercurialis, i. 677; on the cachexia syphiloidea, i. 678; on the eczema mercuriale, i. 679; on the treatment of erethismus mercurialis and eczema mercuriale, i. 680.

Pelletan on the mechanism of the fat rupture when it descends through the inguinal canal, ii. 62; case of the existence of several aneurisms in the same person, ii. 204.

Pellieux on the symptoms of dislocation of the sternal end of the clavicle backwards, i. 778.

Pelouze's experiments on stone-solvents, ii. 554.

Pelvic bones, fracture of, i. 543; dislocation of, i. 775.

Penada's case of hydrocephalocele, ii. 98.

Penis, cancer of, ii. 800; amputation of, ii. 801; by ligature, ii. 802.

Penis, wounds of, i. 487; treatment of these wounds, i. 487; laceration of the cavernous bodies by forcibly binding the penis during erection, i. 487; consequences and treatment, i. 487; South on incising the spongy body of the penis not always a cause of loss of the power of erection, i. 487; Möller's case of gangrene of the penis from the constriction of a metal ring, i. 487; South's objection to amputation of the penis for lacerations of the cavernous bodies, i. 488; rupture of the urethra, i. 488; symptoms and treatment, i. 488; South on the treatment of rupture of the urethra, i. 488.

Pennock, Dr., on the effects of cupping glasses in vipers' bites, i. 353.

Pentzlin on the treatment of itch, i. 639.

Percival, Dr., on an epidemic vaginal catarrh, i. 161.

Percy on the removal of foreign bodies in injuries of the brain, i. 398; on the solution of the chloride of lime in the treatment of foul, gangrenous, or torpid ulcers, i. 615; on passing a leaden thread into Steno's duct, after the cheek has been penetrated, in the operation for salivary fistula, i. 713; operation for enlargement of the tongue, ii. 561; moxa made with the pith of the sun-flower, ii. 883; on the excision of joints, ii. 969.

Pericardium, wounds of, i. 456. *See* Wounds of the Chest.

Perineal fistula, i. 744; abscess, i. 744; rupture, ii. 90.

Perineum, female, lacerations of, i. 608; causes, situation, and extent, i. 608; slight lacerations, i. 608; results of extensive lacerations, i. 608; inability to retain the fæces in complete laceration from the vagina to the rectum, i. 608; treatment of extensive laceration, i. 608; by sutures, i. 608; by position, i. 608; central laceration, i. 608; treatment of large and recent lacerations by the stitch, i. 608; Duparcque on the treatment of lacerations of the perineum, i. 609; results of these lacerations, i. 609; Dr. Churchill on the treatment of lacerated perineum, i. 609; Duparcque on the scarring of the edges of the torn perineum, i. 609; operations on old lacerations when extending into the rectum uncertain in their consequences, i. 610; when contra-indicated, i. 610; description of the operation, i. 610; Ambrose Paré, Guillebonneau, Mauriceau, La Motte, Smellie, Noel, Saucerotte, Dupuytren, Mursinna, Menzel, Osiander, Dieffenbach, Montain, and Roux on this operation, i. 611; Guillebonneau, Mauriceau, La Motte, Smellie, Noel, Saucerotte, Dieffenbach, Roux, Montain, and Ritgeon on the application of sutures, i. 611; Davidson's successful operation, i. 611; subsequent treatment, i. 611; Dieffenbach on the artificial retention of fæces for several days after the operation, i. 612; Saucerotte, Roux, and Davidson's cases, i. 612; Horner's recommendation to divide the sphincter ani, after union has taken place, i. 612; mode of union of old lacerations, i. 612; Nevermann's treatment by cauterizing with unslaked lime, and afterwards by position, i. 612.

Peroneal artery, ligature of, ii. 266.

Perrault's case of amputation at the hip-joint, ii. 933.

Perrez on the physiology of carbuncle, i. 136; on the treatment of carbuncle, i. 139.

Perry's case of aneurism bursting into a vein, ii. 272; case of necrosis of the lower jaw, ii. 994.

Petit's explanation of the lengthening of the limb in hip disease, i. 257; on the reduction of the consecutive dislocation, i. 268; on the arrest of hæmorrhage by nature, i. 297; on the healing of wounds of arteries, i. 298; on the more general application of the trephine, i. 413; bandage and slippers for rupture of the tendo Achillis, i. 493, 494; bandage for fractured clavicle, i. 551; on the rotation of the foot outwards in fracture of the neck of the femur, i. 564; on incision of the hernial sac, etc., for its radical cure, ii. 24; case of impending peritonitis from ligature of the hernial sac, ii. 29; on the operation of dilating the abdominal ring, the hernial sac being unopened, ii. 43; on the coagula in varicose veins, ii. 288; case of varices in the upper extremity, ii. 289; cases in which severe symptoms followed the application of the ligature for piles, ii. 303; mode of amputating by the circular incision, ii. 890.

Peyronie's, M. La, case of abscess of the dura mater, i. 399.

Phagedena, sloughing. *See* Mortification.

Philip's, Dr. Wilson, experiments on the condition of the vessels in inflammation, i. 28; on the treatment of uric acid gravel, ii. 534.

Phillips' case of fracture of the first vertebra, and pivot process of the second, i. 532; post-mortem appearances, i. 534; case of prolapsed womb treated by cauterization of the vaginal parietes, ii. 112; on the application of the actual cautery in treating prolapse, ii. 134; on acupuncture in aneurism, ii. 228; case of a stick in the rectum, ii. 392; on the statistics of the operations for the extirpation of the ovary, ii. 490; on the results of amputation, ii. 905.

Phimosis, ii. 343.

Phlebitis, i. 77; causes, symptoms, and terminations, i. 77; Cruveilhier and South on phlebitis, i. 77, 78; Hunter on the coagulation of the blood in phlebitis, i. 77; Hunter, Abernethy, Hodgson, Carmichael, Bouillaud, Travers, and Arnott on severe phlebitis, i. 78; Ribes' cases of phlebitis, i. 79; Arnott on the morbid appearances in phlebitis, i. 80; Dr. Robert Lee on inflammation of the femoral and iliac veins, an occasional cause of phlegmasia dolens, i. 80; Abernethy on the treatment of traumatic phlebitis, ii. 863.

Phlebotomy, ii. 860.

Phlegmasia dolens, Dr. R. Lee on inflammation of the femoral and iliac veins, an occasional cause of, i. 80.

Phrenic rupture, ii. 92.

Physick, Dr., on the treatment of carbuncle, i. 138; guillotine instrument for amputating the tonsils, i. 145; on the treatment of coxalgia, i. 263; on the animal ligature, i. 307; apparatus for fracture of the neck of the femur, i. 569; on the use of the seton in false joints, i. 593; operation for artificial anus, i. 723; on the mode of performing the Cæsarian operation, ii. 443.

Piedagnel on the cause of death from the entrance of air into a vein, ii. 856.

Pioné on the changes which the substance of bone undergoes in advanced age, i. 497; on sawing off the ends of the broken bone in false joints, i. 591; on the direction and position of natural and acquired hare-lip, i. 595; on the solution of the chloride of lime in the treatment of foul, gangrenous, or torpid ulcers, i. 615; on the treatment of syphilitic phimosis, ii. 348; on hydrocele caused by gonorrhea, ii. 499; on the nature of corns, ii. 668; on the seat of exostosis, ii. 673.

Pilore's case in which he made an artificial anus on the right side by opening the cæcum, ii. 328.

Pinel's opinions relative to the formation of pus. i. 35.

Piorry on the physical characters of dropsy of the pericardium, ii. 479.

Pitcairn, Dr., on immediate amputation in gun-shot wounds, i. 346; on gold and its preparations in primary and secondary syphilis, i. 669.

Pitschaft's cases of suppurating protrusion of the brain in children, ii. 102.

Planchon's case of fatal punctured wound of the womb, i. 486.

Plantade's mode of amputating at the hip-joint with the flap-cut with a single flap, ii. 936.

Plattner's artery-compressor, i. 299.

Plenck on the lengthening of the limb in hip-disease, i. 257.

Ploucquet's case of foreign body in the heart, i. 455.

Pockels on the formation of new vessels, i. 292.

Poisoned Wounds, i. 348. *See* Wounds.

Poller on puncturing the bladder, ii. 436.

Polypus, ii. 726; of the nostrils, ii. 729; of the throat, ii. 738; of the œsophagus, ii. 738; in the maxillary sinus, ii. 739; of the womb, ii. 746; of the vagina, ii. 754; of the rectum. ii. 754.

Popliteal artery, ligature of, ii. 264.

Portal's case of inflammation of the aorta, consequent on the recession of measles, i. 74; on the ossification of arteries in young children, i. 77; case of fatal hæmorrhage consecutive to the opening a tonsillar abscess, i. 142; on the lengthening of the limb in hip-disease, i. 257; mode of amputating by the circular incision, ii. 891.

Portalupi's case of very large fatty tumor, ii. 691.

Porte, De la, on the extirpation of the ovary, ii. 487.

Porter's case of wound of the popliteal artery by a sequestrum, i. 696; on the passage of foreign bodies into the larynx, ii. 394.

Posch's apparatus for fractures of the leg, i. 583.

Posselt's chemical analysis of the fluid contained in ranula, ii. 406.

Post's, Dr., case of ligature of the subclavian above the clavicle, ii. 243; on the ligature of the external iliac, ii. 261.

Pott on the diseased condition of the spine in lumbar abscess, i. 186; on the symptoms and progress of inflammation in the joints of the vertebræ, i. 277; on the so-called palsy of the limbs in Pott's disease, i. 278; on the puffy, circumscribed, indolent tumour of the scalp, indicative of suppuration between the dura mater and the skull, i. 385; on the symptoms accompanying fracture of the skull, not depending on the injury to the bone, but from injury to the brain, or of some of the parts contained in the cranium, i. 389; on puncturing the dura mater, when the extravasation lies beneath, i. 406; on extravasation between the meninges, or on the surface of the brain, i. 406; on the more general application of the trephine, i. 413; on the bent position in fracture of the femur, i. 574; on effusion of blood into cellular tissue of the scrotum, ii. 455; on hæmatocele of the spermatic cord, ii. 457; case of fusible calculus in a vesical rupture, ii. 547; on cancer of the scrotum, ii. 815; on the age at which chimney-sweep's cancer generally occurs, ii. 816; mode of operating in amputation, ii. 892.

Potter on the results of amputation, ii. 905.

Pouteau recommends emetics in hospital gangrene, i. 97; on the application of caustic and the actual cautery in carbuncle, i. 139; on the arrest of hæmorrhage by nature, i. 297; objection to dressing the wound, after the operation for rectal fistula, i. 731.

Powell's, Dr., case of a hydrophobic patient biting another person, i. 369.

Powell's case of rupture of the womb not fatal, i. 484.

Pravaz on the reduction of congenital dislocation of the femur, i. 803; case of successful reduction, i. 804; on acupuncture of the aneurismal sac, and the application of galvanism, ii. 228.

Preiss on the exhibition of purgatives in strangulated hernia, ii. 32; on the operation of dilating the abdominal ring, the hernial sac being unopened, ii. 43.

Pring's case of operation for artificial anus at the lower end of the colon, ii. 329.

Prochaska's case of sympathetic abscess of the brain, with irritation and suppuration of the dura mater, i. 402.

Prolapses:—definition, ii. 102; causes, ii. 103; *prolapse of the womb*, ii. 103; varieties and complications, ii. 103; Sabatier and Blundell on prolapse of, ii. 103; symptoms of incomplete prolapse, ii. 104; Blundell on relaxation and incomplete prolapse, ii. 104; Ramsbotham on the obstruction to the passage of the urine in prolapse of, ii. 104; South on the irritation of the rectum in prolapse of, ii. 105; complete prolapse, symptoms and results, ii. 105; Blundell on the size of the prolapsed womb and vagina, ii. 105; Cruveilhier and South on the contents of the sac formed by the prolapsed vagina, ii. 105; Clarke on the length of time during which the prolapse is forming, ii. 106; Cruveilhier on incontinence of urine in prolapse of the womb, ii. 106; Clarke on the size and shape of the prolapsed organ, ii. 106; Cruveilhier on the altered form and direction of the os uteri in prolapse of that organ, ii. 106; Cruveilhier and Cloquet on the elongation of the womb in cases of prolapse, ii. 106; Ramsbotham on the general symptoms of prolapse and procidentia, ii. 106; Clarke on the consecutive ulceration of the vagina, ii. 106; Cloquet and Cruveilhier on the existence of calculi in the displaced bladder consequent on prolapsus uteri, ii. 106; Cruveilhier and Cloquet on consecutive displacement of the rectum, ii. 107; causes of prolapsus uteri, ii. 107; Blundell and Ramsbotham on the causes of prolapse, ii. 107; Elliotson, S. Cooper, and Ramsbotham's cases of prolapse of the womb in virgins, ii. 107; Ullsamer on endemic prolapse of the womb from the use of the labour-chair, ii. 108; Clarke's case of procidentia uteri, with separation of the bones of the pelvis, ii. 108; prognosis, ii. 108; treatment, ii. 108; mode of reducing the prolapse, ii. 108; Ruysch and Sabatier on the reduction of the prolapsed and ulcerated womb, ii. 109; Sabatier on the treatment of the prolapsed pregnant womb, ii. 109; after-treatment, ii. 109; Clarke on the after-treatment of procidentia uteri, ii. 109; Clarke on the application of injections, ii. 110; Clarke on the treatment of the ulcerated vagina, ii. 110; Clarke's objections to sponge as a pessary, ii. 110; use of pessaries, ii. 110; the oval pessary and its application, ii. 110; Clarke's pessary, ii. 111; inconvenience of pessaries, ii. 111; Hull's utero-abdominal supporter, ii. 111; King's bandage, ii. 112; Phillips' case of prolapse treated by cauterization of the parietes of the vagina, ii. 112; Clarke on the corrosion of pessaries in the passage, and on the deposit of calculous matter on them, ii. 112; Hall, Ireland, Velpeau, and Bérard's operation for prolapse, ii. 112; Dieffenbach and Lawrie on the use of the actual cautery in prolapse, ii. 113; Ker's case of procidentia treated with the secale cornutum, ii. 113; Bellini's operation, ii. 113; Fricke's operation of episioraphy, ii. 114; Gedding's cases in which episioraphy was performed, ii. 114; symptoms sometimes following the reduction of an old prolapse, ii. 115; removal of the prolapsed organ when scirrhous, by the ligature or by incision, ii. 115; introduction of the catheter in cases of prolapse, ii. 115; Recamier, Marjolin, Cruveilhier, and Langenbeck on excision of the prolapsed scirrhous womb, ii. 115; *prolapse of the womb with inversion*, ii. 115; definition, ii. 115; varieties, ii. 116; Crosse on the characters of the respective varieties, ii. 116; Crosse on the successive steps of the inverting process, ii. 116; Crosse on the concavity formed in all cases of inversion, ii. 117; causes, ii. 117; Hachmann on spontaneous inversion from spasm, ii. 117; Clarke and Crosse on polypus of the fundus uteri as a cause of inversion, ii. 117; Crosse on coagulated blood, hydatids and moles in the womb as causes of inversion, ii. 118; symptoms of the quickly-formed inversion, ii. 118; Dailliez on strangulation of intestine in the concavity formed by the inverted womb, ii. 118; Clarke on the character of the discharge in inverted uterus, ii. 119; diagnosis of inversion from prolapse, ii. 119; reduction of the inverted womb, ii. 119; after-treatment, ii. 119; treatment when the reduction cannot be effected, ii. 119; when the placenta is attached to the inverted organ, ii. 120; in chronic inversion, ii. 120; Clarke on the treatment of chronic inversion, ii. 120; Clarke on the treatment of recent inversion, ii. 120; Clarke on the diagnosis between chronic inversion and polypus uteri, ii. 120; treatment when the reduction of the inverted organ is impossible, ii. 120; removal of the inverted womb, if affected with cancer or other degeneration, ii. 120; Clarke on the treatment of the inverted womb, complicated with procidentia, ii. 121; Clarke, Chevalier, Blundell, Dr. J. Clarke, and Dr. Symonds' cases of removal of the inverted womb by ligature, ii. 121; *prolapse of the vagina*, ii. 122; definition and varieties, ii. 122: Clarke and John Burns on prolapse of the vagina, ii. 122; characters of complete prolapse, ii. 122; of imperfect prolapse, ii. 122; diagnosis between prolapse of the vagina and of the womb, ii. 122; Clarke and Blundell on the symptoms of prolapse of the vagina, ii. 122; predisposing and occasional causes, ii. 123; Clarke on the causes and symptoms of posterior prolapse of the vagina, ii. 123; reduction of the prolapse, ii. 123; Clarke on the treatment of posterior prolapse, ii. 123; after-treatment, ii. 124; *prolapse of the bladder*, ii. 124; symptoms, ii. 124; diagnosis between prolapse of the bladder and of the womb, ii. 125; treatment, ii. 125; South's case of prolapse of the bladder relieved by operation, ii. 126; Lightfoot's case in which he performed the operation of episioraphy, ii. 129; *prolapse of the rectum*, ii. 129; three forms of prolapse of the rectum, ii. 130; Copeland on prolapse of the internal membrane of the rectum, ii. 130; Syme on prolapsus ani, ii. 130; Bushe describes two forms of prolapsed rectum, ii. 130; Bérard jun.'s case of invagination of the rectum through the anus, ii. 130; characters of prolapse of the internal coat of the rectum, ii. 130; of prolapse of all the coats, ii. 131; symptoms, ii. 131; Bushe on the characters of prolapse, ii. 131; Syme on the characters of prolapsus ani, ii. 131; Copeland, Syme, and Bushe on the diagnosis between prolapsed rectum and hæmorrhoids, and intus-susception, ii. 131; causes, ii. 132; Bushe on the changes in the mucous membrane of the rectum in old prolapses, ii. 132; treatment, ii. 132; reduction of the prolapse, ii. 132; Brodie and South on the treatment of prolapse in children, ii. 132; Dupuytren objects to scarifications or leeches in treating prolapse of the rectum, ii. 133; prevention of the return of the prolapse, ii. 133; Klein and Schwarz on the treatment of prolapse, ii. 133; Brodie on the treatment of prolapsed rectum with piles in the adult, ii. 134; Dupuytren's operation for long-standing prolapse, ii. 134; Phillips on the application of the actual cautery in treating prolapse, ii. 134; Hey on the cause of the difficulty in reducing the bowel in old prolapses, ii. 134; Hey's operation, ii. 134; Velpeau's modification, ii. 135; Copeland's operation, ii. 135; M'Cormac on careful traction of the skin in prolapse of the rectum, ii. 136; changes that take place in old prolapses, ii. 136; extirpation of the degenerated parts, ii. 136; Salmon's operation, ii. 136; application of the actual cautery in irreducible prolapse, ii. 136; Ansiaux and Dupuytren on the actual cautery in irreducible prolapse, ii. 136; prolapse of an ensheathed upper intestine, ii. 137; Bushe on relaxation of the anus, ii. 137; causes, signs, and results, ii. 137; Bushe on relaxation of the rectum with invagination of the mucous membrane, ii. 137; causes, symptoms, and treatment, ii. 137; Somme's case, ii. 137; Salmon on the incautious use of enemata a cause of relaxed rectum, ii. 138.

Prostate, retention of urine from inflammation of, ii. 419; suppuration and abscess of, ii. 419; swelling of, from varicose veins, ii. 421; induration of, ii. 421; chronic enlargement of, ii. 422; retention of urine from, ii. 424; stones in the, ii. 633.

Prout, Dr., on the origin of oxalic acid in the urine, ii. 519; on lithic or uric acid sediments, ii. 528; characters of yellow sediments, ii. 528; of red or lateritious sediments, ii. 528; of pink sediments, ii. 528; white lithate or urate of soda sediment, ii. 529; characters and accompanying symptoms of the phosphatic sediments, ii. 529; causes, ii. 530; oxalate of lime sediment, ii. 530; characters of the urine in cystic oxide calculus, ii. 530; characters and symptoms of crystallized uric acid gravel, ii. 531; on the crystallized phosphatic gravel, ii. 532; on the rarity of crystallized oxalate of lime gravel, ii. 532; on the treatment of a fit of the gravel, ii. 535; of cystic oxide gravel, ii. 537; of the oxalate of lime diathesis, ii. 537; of the phosphatic diathesis, ii. 538; on the formation of uric acid calculi in the kidneys, ii. 540; on renal calculi of oxalate of lime, ii. 540; on renal calculi of cystic oxide, ii. 541; on the rarity of phosphatic renal calculi, ii. 541; on the treatment of nephritis complicating renal calculi, ii. 542; on the spontaneous breaking up of calculi in the bladder, ii. 548; on the symptoms of

vesical calculus, ii. 550; on the use of stone solvents, ii. 554.
Psoitis. *See* Inflammation of the Lumbar Muscles.
Psoas abscess, i. 185.
Psora, i. 634.
Pudic, common, ligature of, ii. 258.
Punctured wounds, i. 331. *See* Wounds.
Pus, the secretion of, i. 34; resorption of, i. 36; Vogel and Bonnet on the effects of, i. 36; qualities of pure good pus, i. 38; formation of, i. 39; Travers on the purposes which the formation of pus serves in the economy, i. 39; Hunter on the qualities of pus and the pus globules, i. 39; Hunter and Gulliver on the putrefaction of pus, i. 39; Senac on the globular structure of, i. 39; Gueterbock on the composition and chemical analysis of, i. 40; composition of the serum of, i. 40; fatty vesicles discovered by Henle in the serum of, i. 40; Gueterbock's discovery of pyine, i. 40; characters of pus globules, i 40; Mandt on the pus globules, i. 40; discovery of the difference in size of the pus globules by Gueterbock, i. 41; Mayo describes the occasional occurrence of pus globules in healthy blood, i. 41; denied by Gulliver, i. 41; Gerber's account of the formation of pus, and of the reproductive organization in suppurating wounds, i. 41; Travers on the constitution of pus, i. 42; varieties of, i. 43; distinguishing characters of laudable pus, and ichor or sanies, i. 43; the presence of globules in the serum proved by Bauer, Faraday, and Mandt, i. 43; characters of the albumen in pus, i. 44; Grassmeyer and Fischer on the distinguishing tests for pus and mucus, i. 44; Gruithuisen's microscopic tests for pus and mucus, i. 44; Gerber's description of ichor, puriform mucus, and serous exudation, i. 44; pus cannot be produced without inflammation, i. 44; diathesis purulenta, i. 45.
Pustule, malignant. *See* Mortification.
Puthod's mode of amputating at the hip-joint with the flap-cut with a single flap, ii. 935.

Quassoud on mortification from spurred rye, i. 61.
Quesnay's opinion relative to the formation of pus, i. 35, on the more general application of the trephine, i. 413; on the stanching the bleeding in wound of the intercostal artery, i. 448.
Quinsy. *See* Inflammation of the Tonsils.

Radial artery, ligature of, ii. 253.
Radius, fracture of, i. 557; dislocation of, i. 791.
Rainey on a peculiar degeneration of the cartilage in disease of the knee, i. 273.
Ramel's case of displacement of the heart, ii. 96.
Ramsbotham, Dr., on the obstruction to the passage of the urine in prolapse of the womb, ii. 104; on the general symptoms of prolapse and procidentia, ii. 106; on the causes of the prolapse, ii. 107; cases of prolapse in a virgin, ii. 108.
Ramsden's case of lumbar abscess, i. 187; of fatal contraction and ulceration of the intestine, after strangulation, ii. 49; of ligature of the subclavian above the clavicle, ii. 243.
Ranby on immediate amputation in gunshot wounds, i. 345.
Ranula, ii. 404.
Rau's mode of operating for stone, ii. 578.
Ravaton's slippers for rupture of the tendo Achillis, i. 494.
Ravin on increased pressure and the supine posture in the radical cure for hernia, ii. 23.
Rayer on erysipelas, i. 100; opinion that carbuncle occurs most frequently in spring and summer, i. 137; on incisions in carbuncle, i. 138.
Raynaud's operation for varicocele, ii. 297.
Recamier on the excision of the prolapsed and scirrhous womb, ii. 115; fatal operation for ovarian dropsy, ii. 488; on compression in scirrhus, ii. 770; operation when the neck of the womb is softened or destroyed, ii. 822; cases of removal of the womb by ligature, ii. 824; on extirpation of the womb, ii. 827.
Rectal fistula, i. 726.
——— rupture, ii. 91.
Recto-urethral fistula, i. 747.
———vaginal ———, i. 760.
———vesical ———, i. 747.
Rectum, prolapse of, ii. 129; stricture of, ii. 324; foreign bodies in the, ii. 392; polypus of, ii. 754.
Regal de Gaillac on extirpation of bronchocele by subcutaneous ligature, ii. 664.
Regnault's case of re-union of divided parts, ii. 835.
Regnoli's operation for the extirpation of the tongue, ii. 779.
Reinhardt on the mode of reducing dislocations of the thumb from the metacarpal bone, i. 795.
Reisinger's apparatus for ligaturing complete rectal fistulæ, i. 733; mode of applying the apparatus, i. 733.
Renal calculi, ii. 539.
Rénaud's apparatus for simultaneous fracture of both clavicles, i. 551.
Rennerth on the exhibition of purgatives, &c., in strangulated hernia, ii. 32.
Renucci on the existence of the acarus scabiei, i. 636.
Reybard's canula useless in wounds of the intercostal artery, i. 447; plan for stanch-

ing bleeding from the intercostal artery, i. 447; mode of practice in wounded intestine, i. 465; modification of Dupuytren's operation for artificial anus, i. 723.

Reynaud on the treatment of buboes, i. 659.

Resolution, a result of inflammation, i. 31; signs of resolution, i. 31; distinguished from the recession of inflammation, i. 31; Dr. J. H. Bennett on the process of resolution, i. 31; Schönlein and Zimmermann on the elimination of the molecular fibrin, i. 32; resolution, an ordinary termination of orchitis, i. 179.

Rheumatism, gonorrheal, i. 217.

Rhinoplasty, ii. 833.

Riadore's case of excision of part of the hand, ii. 965.

Ribes' cases of phlebitis, i. 79; on the internal opening of rectal fistula, i. 726; on the application of the taxis in strangulated hernia, ii. 32.

Ribieri on local anodyne applications in strangulated hernia, ii. 32.

Ribs, fracture of, i. 546; dislocation of, and of their cartilages, i. 776; resection of, ii. 1005.

Richerand on the treatment of ingrowing of the nail, i. 199; of fractured clavicle, i. 551; of fracture of the neck of the humerus, i. 554; of the neck of the femur, i. 570; on the primitive direction of dislocation of the humerus, i. 782; on puncturing the distended intestine, after the operation for strangulated hernia, ii. 39; on the occurrence of aneurism in dissecting-room servants, ii. 202; on the application of pounded ice to aneurisms, ii. 207; on compression in the treatment of aneurism, ii. 210; on the respective origins of benignant and malignant nasal polypi, ii. 731; objections to the upper flap in partial amputation of the foot, ii. 948.

Richon on the treatment of gonorrhea, i. 175.

Richter on the extirpation of the tonsils by cutting, i. 145; on dry whitlow, i. 194; on the lengthening of the limb in hip-disease, i. 257; on the resection of the carious head of the femur in hip disease, i. 270; only employs trepanning in injuries of the head when secondary symptoms of irritation and pressure require it, i. 412; gutter-shaped piece of card-board useless in wounds of an intercostal artery, i. 447; bandage for fractured clavicle, i. 551; on the treatment of salivary fistula, i. 713; objections to the use of the catheter in urethral fistula, i. 745; on the *reduction en masse*, ii. 16; on increased pressure and the supine posture for the radical cure of hernia, ii. 23; on the radical cure by incision and scarifications of the sac, ii. 24; on dilatation of the stricture in strangulated hernia, without cutting, ii. 38; case of yielding of the abdominal parietes, ii. 85; cauterizes ranula in children with lunar caustic, ii. 407; mode of amputating by the circular incision, ii. 891.

Ricord on acute urethritis in the female, i. 159; on utero-vaginal gonorrhea, i. 159; regards ovaritis as a complication of gonorrhea, i. 159; on abscesses complicating gonorrhea, i. 160; experiments on the identity of gonorrhea and syphilis, i. 162, 165; inferences from the results of the inoculation of gonorrheal matter, i. 165; opinion that gonorrhea is unattended by ulceration controverted, i. 166; on the examination of public prostitutes, i. 167; treatment of gonorrhea by the direct application of nitrate of silver, i. 170; on the remedies for chordee, i. 170; on the arrest of hæmorrhage from the urethra, i. 170; on the treatment of gonorrhea in women, i. 171; treatment of severe cases by the introduction of a plug of lint dipped in some emollient narcotic liquid, i. 172; treatment of obstinate cases by filling the vagina with dry lint, i. 172; ulcerations and papulous granulations to be cauterized, i. 172; on ulcerations of the mucous membrane of the womb, i. 172; vegetations in the interior of the urethra to be destroyed by incision or cauterization, i. 172; on gonorrhea in the female urethra, i. 172; on inoculation with gonorrheal matter to cure gleet, i. 174; on the treatment of balanitis, i. 176; on syphilitic swelling of the testicle, i. 178; describes it as syphilitic sarcocele, i. 178; on the period at which chancres appear after infection, i. 642; on inoculation for the purpose of distinguishing syphilitic sores, whether primary or secondary, i. 644; on the seven kinds of buboes, i. 645; on the existence of syphilitic buboes without primary sore, i. 647; on the non-infectious character of the pus from a secondary syphilitic sore, i. 649; on the causes of the varied appearances of chancre or primary syphilitic sore, i. 653; on the destruction of the ulcer by the nitrate of silver, i. 655; on the treatment of buboes, i. 659; on iodine in gonorrhea and bubo, i. 669; on the possibility of infection from secondary syphilis, i. 675; on urethroplasty, i. 742; on the application of the ligature in the treatment of varix, ii. 291.

Rietgen on the mode of performing the Cæsarian operation, ii. 443.

Rigby, Dr., on puerperal abscess, following contagious or adynamic puerperal fever, i. 47; on wounds of the uterus, as predisposing to rupture in subsequent labours, i. 484; on retroversion of the womb in the unimpregnated state, ii. 139; on examination by the vagina and rectum, and by the uterine sound, in retroflexion of the womb, ii. 141; on the symptoms of retroversion, ii. 142; on the mechanical support to the womb requisite after the reduction of the retroversion, ii. 145; on the circumstances authorizing the Cæsarian operation, ii. 437; on the propriety of not operating until after labour has commenced, ii. 439.

Ritgen on the application of the sutures in the operation for lacerated perineum, i. 611.

Ritter's idea that boils depend on the retention of the animal refuse, i. 135.

Robertson, Dr., on bronchocele as a variety of scrofula, ii. 656.

Robertson's case of ligature of the carotid, ii. 233.

Robinson, Dr., recommends the removal of the acromion and glenoid cavity in amputation at the shoulder-joint, ii. 960.

Robinson on the inhalation of ether prior to the extraction of teeth, ii. 1008.

Robison's, Dr., case of tetanus, i. 377.

Rochoux on hydrocele caused by gonorrhea, ii. 498.

Rodgers', Dr., successful operation for the establishment of a false joint in a case of anchylosis, i. 248; mode of operating in exarticulation of the fore-arm at the elbow, ii. 962.

Rodriques, Dr., on the effects of cupping-glasses in viper bites, i. 353.

Rogers' case of trepanning the spine, i. 538; on the treatment of branching aneurism, ii. 275.

Rognetta on the treatment of vesico-vaginal fistula by compression with an elastic oval pessary, i. 752; on dislocation of the astragalus inwards, i. 810; on the causes of splay-foot, ii. 186.

Rokitansky on internal strangulation, ii. 94.

Roonhuysen on the use of the suture in vesico-vaginal fistula, i. 753.

Roots', Dr., case of human horns, ii. 670.

Rose on the duration of syphilis under the non-mercurial treatment, and on the subsequent occurrence of secondary symptoms, i. 671.

Roser on dislocation of the thumb from the metacarpal bone, i. 794; on the cause of the difficulty experienced in reducing this dislocation, i. 795; on the mode of reducing this dislocation, i. 795.

Rossi's mode of amputating at the knee with the flap-cut, ii. 943.

Rothmund on the treatment of umbilical rupture occurring after birth, ii. 81.

Rousseau's mode of extirpating piles, ii. 302.

Roux on the introduction of a piece of bougie into an ossified artery after amputation, i. 304; on the removal of the edges of the cleft in staphyloraphy, i. 604; plan for bringing the edges of the cleft together, i. 604; operation when the cleft is very large and complicated, i. 606; fatal case from pneumonia, i. 607; on the operation for lacerated perineum, i. 611; on the application of the sutures, i. 611; case of artificial retention of fæces after the operation, i. 612; on the suture in vesico-vaginal fistula, i. 755; cases of extirpation of the womb, ii. 828; on the excision of joints, ii. 969; mode of operating in excision of the wrist, ii. 976; case of excision of the heads of metatarsal bones, ii. 985; case of resection of the clavicle, ii. 1003; case of resection of a rib, on account of necrosis, ii. 1006.

Rouyer on dislocation of the upper end of the radius forwards, i. 791.

Roy, De, on the making an artificial opening in the cheek in the operation for salivary fistula, i. 713.

Rudolphi on the causes of club-foot, ii. 176.

Rudtorffer's plan to prevent re-union after the operation for united fingers and toes, ii. 309.

Ruetenich's apparatus for fracture of the lower jaw, i. 529.

Rühl's artificial leg, ii. 846; wooden leg, ii. 847.

Rupture (hernia), ii. 1.

Russell on the appearances of white swelling on dissection, i. 275; on the treatment of scrofulous ulcers, i. 624.

Russell, Dr., confirms Celsus' observations on the innocuous qualities of the poison of serpents, when introduced into the mouth, i. 354; on the symptoms produced by the bite of a cobra di capello, i. 357; cases of fatal snake-bite, i. 358; on the treatment of snake-bites in India, with the Tanjore pill, i. 359; on the physical qualities of snake-poison, i. 359.

Rust's opinion that the so-called lymph-swelling is an extravasation of lymph, i. 48; on injecting boiling water into a cold abscess, i. 90; division of erysipelas into true and false, i. 99; on the application of moist warmth in vesicular erysipelas and its varieties, i. 106; on incisions in pseudo-erysipelas, i. 108; explanation of the shortening of the affected limb in hip-disease incorrect, i. 256; explanation of the lengthening of the limb, i. 257; objects to the use of issues in hip-disease, i. 265; on warm bathing in, i. 267; on the mercurial treatment in, i. 267; on the general treatment of coxalgy, i. 267; on the treatment of abscesses at the hip, i. 269; advises their being opened by the actual cautery, i. 269; advises passing a seton through the joint, i. 269; explanation of wounds from the wind of a ball, i. 339; case of simple dislocation of the spine, i. 535; treatment of chronic ulcers of the foot by the hunger-cure, i. 619; treatment of syphilitic ulceration of the throat and palate, i. 660; on the friction-cure in syphilis, i. 663; on the treatment of caries, i. 686; mode of reducing dislocation of the humerus, i. 784; method of replacement of the dislocated femur, i. 798, 800; on the nature of strangulation in ruptures, ii. 11; on ligature of the external iliac, ii. 261.

Ruyer's case of exarticulation of metatarsal bones, with the diseased bones of the tarsus, ii. 953.

Ruysch on the reduction of the prolapsed and ulcerated womb, ii. 109.

Ryan's, Dr., case of wound of the neck, involving the œsophagus, i. 436; on the treatment of hæmorrhage consecutive to extraction of a tooth, i. 709.

Sabatier advises the opening of abscesses at the hip with caustic, i. 269; more general application of the trephine, i. 413; plan for arresting bleeding from the intercostal artery, i. 448; apparatus for fracture of the neck of the femur, i. 569; internal opening of rectal fistula, i. 726; *reduction en masse*, ii. 16; case of rupture of the lungs, ii. 95; prolapse of the womb, ii. 103; reduction of the prolapsed and ulcerated womb, ii. 109; treatment of the prolapsed pregnant womb, ii. 109; excision of joints, ii. 969; mode of operating in excision of the head of the humerus, ii. 974.

Sachs on the operation for the treatment of ingrowing of the nail, i. 200.

Sacrum, fracture of, i. 543.

Salamon's treatment of fractured clavicle, i. 552; operation for ligature of the common iliac, ii. 256.

Salemy's mode of amputating through the leg in its lower third, ii. 917.

Salivary fistula, i. 712.

——— calculus, ii. 406.

Salle, De, on the treatment of gonorrhea, i. 175; on iodine in hard swellings of the testicle, i. 669.

Salmon's operation for the extirpation of the degenerated prolapse of the rectum, ii. 136; incautious use of enemata a cause of relaxed rectum, ii. 138; seat of stricture in the rectum, ii. 336.

Sams' case of cerebral irritation preceding orchitis, consequent on gonorrhea, i. 179.

Sanctorius' lithotritic instruments, ii. 558.

Sandifort on congenital dislocation of the hip, i. 769.

Sanson on dressing the wound after the operation for rectal fistula, i. 731; on the *reduction en masse*, ii. 16; on the retraction of the tendons of the fingers, ii. 193; modes of performing the recto-vesical operation for stone, ii. 612; mode of amputating at the hip-joint with two flaps, ii. 940; at the shoulder-joint with the circular cut, ii. 958; mode of operating in excision of the knee-joint, ii. 981.

Sarcocele, ii. 804; syphilitic, i. 178.

Sarcomatous tumors, ii. 710.

Sartorius on the section of the tendo Achillis in club-foot, ii. 182.

Saucerotte on the operation for lacerated perineum, i. 611; on the application of sutures, i. 611; case of artificial retention of fæces after the operation, i. 612.

Sauter's apparatus for fracture of the neck of the femur, i. 570; on permanent extension in fracture of the femur, i. 574; apparatus for permanent extension in fractures of the leg, i. 583; plan of reducing dislocation of the humerus, i. 785; directions for the extirpation of the womb, ii. 824.

Saviard on mortification from spurred rye, i. 61; on the healing of wounds of arteries, i. 298.

Scabies, scabies spuria, i. 634, 635.

Scapula, fracture of, i. 548; resection of, ii. 1002; with the clavicle, ii. 1004.

Scarification, ii. 867.

Scarpa on the healing of wounds of arteries, i. 298; experiments on the ligature of arteries, i. 303; experiment with the ligature and cylinder of linen, i. 304; practice in wounded intestine, i. 464; on the production of callus, i. 501; on the appearances presented on post-mortem examination, some time after the cure of an artificial anus, i. 720; on the nature of strangulation in ruptures, ii. 11; on the *reduction en masse*, ii. 16; on dilatation of the stricture in strangulated hernia without cutting, ii. 38; modification of the operation for femoral rupture, ii. 73; opposed to the radical cure of umbilical rupture by ligature, ii. 83; treats ischiatic rupture as enlarged pudic rupture in women, and enlarged perineal rupture in men, ii. 87; on the causes of club-foot, ii. 176; machine for club-foot, ii. 180; views respecting the non-expansion of all the arterial coats in aneurism not always correct, ii. 205; on the application of the ligature, ii. 218; on the effects produced by the ligature on the arterial coats, ii. 219; on ligature of the external iliac, ii. 261; on the division of the prostate, ii. 583; on the diagnosis between scrofula and scirrhus, ii. 762; on the nature of scirrhus, ii. 768; case of lacteal swelling, ii. 789.

Schaack on tapping a cold abscess with the trocar, and injecting red wine, or a solution of bichloride of mercury or nitrate of silver, i. 90.

Schallein's, von, prophylactic treatment of hydrophobia, i. 374.

Schindler's artery-compressor, i. 299; on the more general application of the trephine, i. 413; mode of operating in excision of the lower jaw with the condyles, ii. 989; on the previous ligature of the carotid artery, ii. 990.

Schmalkalden on the treatment of artificial anus, i. 723.

Schmalz on the effects of electrifying patients in doubtful cases of mercurial disease, i. 680.

Schmitt's obturator for vesico-vaginal fistula, i. 751.

Schmucker's case of concussion, i. 411; case of wound of the womb, i. 486; on ligature of the hernial sac for its radical cure, ii. 24; case of spontaneous rupture of the ovarian cyst, ii. 491.

Schneider's case of reduction of the consecutive dislocation in hip-disease, i. 268; bandage for rupture of the tendo Achillis, i. 493.

Schönlein on the elimination of the molecular fibrin, i. 32.

Schreger on the lengthening of the limb in hip-disease, i. 257: on dislocation of the head of the thigh-bone downwards and inwards in hip-disease, i. 258; case of reduction of the consecutive dislocation, i. 268; on the treatment of salivary fistula, i. 713; apparatus for ligaturing complete rectal fistulæ, i. 733; on the use of the suture in vesico-vaginal fistula, i. 753, 755; on congenital dislocation of the hip, i. 769; on the causes of congenital dislocations, i. 769; on incision of the hernial sac and the introduction of lint-tents, to effect the radical cure, ii. 24; indications when the operation for the radical cure is admissible, ii. 28; operation for cartilaginous bodies in the shoulder-joint, ii. 710; on the complication of nasal polypus with teleangiectasy, ii. 731; mode of amputating the penis near the pubic bones, ii. 801.

Schreiner's mode of amputating, ii. 892.

Schuh's case of partial dislocation of the vertebræ, i. 536.

Schumer never found any trace of inflammation in cartilage, i. 236.

Schürmayer's apparatus for fracture of the neck of the femur, i. 570.

Schwann's opinion on the formation of new vessels, i. 292.

Schwarz on the treatment of prolapse of the rectum, ii. 133.

Schwenke on the lengthening of the limb in hip-disease, i. 257.

Schwerdt's cleft-needle for the introduction of the thread in staphyloraphy, i. 605.

Scoliosis, ii. 158.

Scott's case of abscesses of the hip-joint, i. 254; plan of treatment of hip-disease, i. 263; case of wounded stomach without protrusion, i. 475.

Scoutteten's operation for the destruction of the matrix of the nail, i. 200; on the causes of club-foot, ii. 176; on the section of the tendo Achillis in club-foot, ii. 182; mode of operating in exarticulating a bone, ii. 931; mode of operating for amputation at the hip-joint, ii. 940; oval cut in partial amputation of the foot, ii. 949; mode of operating in exarticulation of the metatarsal bones, ii. 950; in exarticulation of the metatarsal bone of the great toe, ii. 952; in exarticulation of the toes, ii. 954; amputation at the shoulder-joint with the oval cut, ii. 958; mode of operating in exarticulation of the metacarpal bones of the ring and little fingers, ii. 964; oval cut in exarticulation of the middle metacarpal bone, ii. 964.

Scrotum, frost-bitten, i. 126; sarcomatous, ii. 805; cancer of, ii. 815.

Scultetus' artery-compressor, i. 299.

Sebaceous tumors, ii. 697.

Sedillot's oblique cut in amputations, ii. 892.

Segalas' caustic-holder for stricture of the urethra, ii. 370.

Seiler's modification of Dupuytren's enterotome, i. 723; on the nature of strangulation in rupture, ii. 12; on the operation for strangulated ischiatic rupture, ii. 87; on the posterior labial rupture, ii. 91.

Selwyn's, Dr. **Congreve**, case of recovery from wound of the brain, i. 397.

Senac on the globular structure of pus, i. 39.

Senff on ligature of the hernial sac for its radical cure, ii. 24.

Sennertus on aneurismal varix, ii. 269.

Serres' case of aneurism of the basilar artery, ii. 240.

Seton, introduction of, ii. 870.

Seutin on the treatment of compound fractures, i. 512; on the starch bandage in fractured ribs, i. 547; treatment of fracture of the humerus, i. 556; application of the permanent apparatus in fracture of the femur, i. 575; in fractures of the bones of the leg, i. 583; case of excision of the head of the femur, ii. 978; case of resection of the fibula, ii. 1007.

Severinus on cauterizing the tonsils with red-hot iron or caustic, i. 145.

Sharp on tying the tonsils, i. 145; on the arrest of hæmorrhage by nature, i. 297; on Cheselden's operation for stone, ii. 586; mode of amputating at the shoulder-joint by the circular cut, ii. 958.

Shaw's case of extirpation of the tonsil, followed by superficial slough, alarming hæmorrhage, and ligature of the carotid, i. 146; on dissection-wounds and their treatment, i. 349; case of fatal hæmorrhage during lithotomy from wound of dorsal artery of the penis, ii. 603.

Sheldon's treatment of fractured olecranon, i. 560.

Shipton's experiments on wounded intestine, i. 465.

Shoulder, curvature of, ii. 191; exarticulation of the arm at, ii. 954; excision of the head of the humerus at, ii. 974.

Shoval's case of gastrotomy for the removal of a knife from the stomach, ii. 391.

Siebold, von, on tying the tonsils, i. 145; case of yielding of the abdominal parietes, ii. 85; of extirpation of the womb, ii. 825; mode of amputating, ii. 892.

Sigebert on mortification from spurred rye, i. 61.

Signohoni's modification of Gerdy's operation for the radical cure of rupture, ii. 25.

Simpson, Dr. on cauliflower excrescence of the os uteri, ii. 818; on the mode of using the speculum vaginæ, ii. 820.

Simpson, opinions of, relative to the formation of pus, i. 35; adaptation of Thorbern's staphylotome to the extirpation of the tonsils, i. 145.

Sinogovitz on the nature of strangulation in rupture, ii. 12.

Skin, cancer of, ii. 763.

Sköda on the formation of new vessels, i. 292.

Skull, fractures of the, i. 389; fungus of, ii. 683.

Smee's experiments on substances adapted for the immoveable apparatus for fractures, i. 505.

Smellie, Dr. on the operation for lacerated perineum, i. 611; on the application of the sutures, i. 611.

Smith on morbus coxæ senilis, i. 260; on colchicum in tetanus, i. 381; case of trepanning the spine, i. 538; on some of the signs of fracture of the neck of the femur, i. 564; fracture-bed, i 571; on the reduction of old dislocations, i. 767; case of congenital dislocation of the lower jaw, i. 772; on the post-mortem appearances in congenital subacromial dislocation, i. 787; on the resemblance between the congenital subcoracoid dislocation, and the partial dislocation of the humerus, and that caused by rheumatic affection of the shoulder-joint, or by unusual atrophy of the upper-arm, i. 788; on the treatment of teleangiectasy by inserting threads dipped in solution of nitrate of silver, ii. 285; on the statistics of lithotomy, ii 545; case of large calculus, ii. 546.

Soemmering's preparation of fracture of the neck of the femur within the capsular ligament united by callus, i. 567; case of spontaneous cure of umbilical rupture, ii. 82.

Softening, i. 53.

Solander's, Dr. sufferings from exposure to cold, i. 126.

Solera's operation for varix by cutting through the vein above and below, ii. 292.

Solingen on amputating just above the ancle, ii. 921.

Solly's case of gangrene, i. 60; case of frost-bite, i. 127; case of recto-vesical operation for stone, ii. 612.

Somme's case of relaxed rectum, with invagination of the mucous membrane, ii. 137.

South's case of cold abscess, i. 45; of lymph-abscess, i. 49; on vesications filled with a blueish or blueish black fluid in cases of severe bruise, or when the bandages used in fracture are too tight, i. 55; case of mortification of the lower extremity from effusion of blood causing distension of the limb, i. 55; cases of mortification after fever, i. 56; of dry gangrene consequent on abdominal typhus, i. 59; of dry gangrene from organic disease of the heart, i. 59; of arteritis without gangrene, i. 60; of noma in the adult, i. 62; on the sloughing state of stumps from want of power, i. 70; on inflammation of the cellular tissue, i. 72; on the tendency of serous membranes to adhesive inflammation, i. 73; case of arteritis, i. 75; on phlebitis, i. 77, 78; on the causes of inflammation of the absorbents, i. 80; on earthy deposits in the absorbents, i. 81; recommends the early opening of abscesses just beneath the skin, and in glandular structures, i. 87; condemnation of pressure and squeezing an abscess, i. 88; on opening an abscess, i. 89; amputation should never be performed while gangrene is in progress, i 95; on erysipelas and erythema, i. 99, 100; case of degeneration of the cellular tissue of the forehead and face, i. 104; the constitutional and local treatment of simple erysipelas, i. 106, 107; on the treatment of erythema symptomaticum by incisions, i. 108; on the application of the nitrate of silver in erysipelas, i. 108; on burns, i. 111; burns generally more dangerous than scalds, i. 111; complete immersion of a person in boiling water, fatal in ten or fifteen minutes, i. 111; persons whose entire surface has been charred by fire may live several hours, i. 111; danger of burns and scalds the greater, in reference to the part injured, i. 111; use of flour in the treatment of burns, i. 116; treatment of burns and scalds, i. 118; internal treatment of burns and scalds, i. 120; effects of the contraction of cicatrices, i. 121; case in which the cicatrix was dissected out, i. 122; parallelism of the effects of great degrees of heat and cold on the animal body, i. 125; mustard liniment in the treatment of chilblains, i. 131; treatment of boils by free incision, i. 134; recommends the employment of general treatment in cases of boils, i. 135; rarity of carbuncle on the head i. 137; treatment of carbuncle, i. 138; recommends the actual cautery in cases in which an arterial branch has been wounded in scarifying the tonsils, i. 141; directions for opening a tonsillar abscess, i. 142; treatment of enlarged tonsils, i. 143; amputation of the tonsils, i. 146; opinion against excision of the uvula, i. 147; on the arrest of the secretion of milk, and its absorption, i. 151; recommends abscess of the breast to be opened freely and early, i. 151; advantages of the proceeding, i. 152; condemns Langenbeck's plan of treating the fistulæ, i. 152; treatment of fistulæ, i. 152; case of chronic abscess of the breast, operated on by mistake for scirrhus, i. 153; on retention of urine in severe gonorrhea, i. 158; on gonorrhea virulenta, a constitutional disease in certain persons, i. 162; frequency of the co-occurrence of chancre and gonorrhea, i. 164; gonorrheal sore throat, i. 166; treatment of gonorrhea, i. 169; of painful erections and chordee, i. 170; arrest of hæmorrhage from the urethra, i. 170; treatment of gonorrhea in women, i. 171; on gleet, i. 173; on the infectious nature of, i. 173; condemnation of the practice of inoculating with gonorrhea to cure gleet, i. 174; on cubebs and copaiba in gonorrhea, i. 176; on balanitis, i. 176; treatment of balanitis, i. 176; doubts swelling of the testicle being ever dependent on a syphilitic origin, i. 178; on congestion of the semen in the seminal tubes, as a cause of orchitis, i. 178; wasting of the testicle, caused by inflammation, i. 180; treatment of orchitis, i. 181; of fungus of the testicle, consecutive to abscess, i. 181; of orchitis by compression, i. 182; on the application of compression, i. 183; results of compression, i. 183; case of metastasis of gonorrhea and inflammation of the testicle to the brain, i. 183; origin of lumbar abscess from external violence, i. 187; distinctive character of psoas abscess from femoral hernia, i. 187; insidious progress of the disease, i. 188; controverts Astley Cooper's opinion that the abscess should be allowed to take its course, i. 188; on issues in the treatment of lumbar or psoas abscess, i. 188; condemns the practice of passing a seton through a lumbar abscess, and prefers puncturing it with a lancet, i. 189; treatment of the abscess, i. 190; paronychia cellulosa, i. 193; on the tendency of the tendinous and cellular whitlows to run into each other, i. 194; on the free incision and subsequent treatment of whitlow, i. 196; directions for the treatment of the second variety of whitlow, i. 197; of the third variety of whitlow, and the necessity for free and deep incisions, i. 197; contravenes Cooper's statement that the application of a blister will often bring away the nail in cases of ingrowing, i. 200; condemns Cooper's operations for the removal of the diseased nail, i. 201; on the evulsion of the nail in onychia maligna, i. 203; treatment of onychia by the destruction of the nail-gland with nitric acid, i. 204; absence of discriminating signs between simple acute inflammation of the ligaments and rheumatism, i. 207; relaxation of the ligaments, i. 209; cases of abscesses external to the joint, i. 210; position of the limb during disease of the knee-joint, i. 211; non-malignancy of pulpy degeneration of the synovial membrane, i. 218; local treatment of synovial inflammation, i. 219; if suppuration ensue, the swelling should be punctured early, i. 220; use of blisters in promoting the absorption of the effused fluid, i. 220; on irritant applications in the treatment of chronic synovial inflammation, i. 221; case of disease of the synovial membrane of the knee, attended with evidence of fluctuation, in which the swelling was punctured without benefit, i. 222; considers that ulceration of cartilages differs from common inflammation of the synovial membranes, and of the spongy ends of bones, i. 236; opinion that the occurrence of scrofulous disease in the joints has suspended the progress of some other and perhaps more serious disease elsewhere, i. 240; has seen the connecting medium in anchylosis composed partly of ligamento-fibrous, and partly of bony matter, i. 240; on the ivory-like covering of the joint-surfaces of bones. i. 240; removal of the articular cartilages in old age, as the result of previous ulceration, i. 241; views on anchylosis differ somewhat from those of Hunter, i. 242; on soft anchylosis from granulations, i. 242; cases of fibrous anchylosis, i. 243; of the complication of bony and fibrous anchylosis, i. 245; on the constitutional treatment of hysterical affections of the joints, i. 250; on the pain on the inside of the knee in hip disease, i. 252; on the shortening of the limb, i. 256; explanation of the lengthening of the limb, i. 257; on the appearances after death in hip-disease, i. 258; on the sympathetic pain in the hip from disordered bowels, i. 260; on the morbus coxæ senilis, i. 260; the use of issues approved of, i. 265; the actual cautery or burning cylinders preferable in all cases where the limb is much lengthened, the muscles relaxed, and where there is great swelling from collection of fluid, i. 265; Brodie's plan of treating issues approved of, i. 265; management of abscesses at the hip, i. 269; diagnostic symptoms of the diseases of the knee, i. 272; diagnostic sign for vertebral caries, i. 281; diagnosis between curvature of the spine from caries and that from rickets, i. 281; meaning of "quick union," i. 290; application of the tourniquet, i. 299; treatment of protracted oozing of blood, i, 301; of epistaxis, i. 302; wounds of the pudic artery and artery of the bulb during the lateral operation for the stone, i. 302; treatment of wounded arteries in the thick fleshy parts of the hand or foot, i. 302; experiment on the carotid of a dog, i. 303: on the application of the ligature, i. 304; ligature of large arteries above and below the wound, i. 305; necessity for cutting down upon a wounded vessel on the sound side of a limb, if nearer the artery than is the part wounded, i. 305; after-management of the ligature, i. 306; opinion that the ligature should be allowed to come away, as the result of the suppurating process, i. 308; management of a long-retained ligature, i. 308; on torsion, i. 311; treatment of bleeding ossified vessels, i. 318; on venous bleeding in operations, i. 319; case of fatal venous bleeding during amputation of the breast, i. 319; use of bandages for wounds, i. 324; advantages and disadvantages of sutures, i. 326; number of sutures to be used, and the mode of their application, i. 326; objections to stuffing a wound which must heal by granulation, i. 329; regeneration of the nerves, and the recovery of their function after division, i 330; on the tearing or stripping down of large pieces of skin, i. 333; on torn wounds of the scalp, i. 334; on the sloughing which generally follows extensive laceration of the skin of the limbs, i. 334; on extensive ecchymosis, and the means of diagnosis, when an artery of any material size is wounded, i. 334; treatment of the swelling, i. 334; danger of gangrene when a large artery has been wounded, from the distension of the soft parts, i. 334; cases of severe injury from small shot, i. 336; objects to the application of caustic in dissection-wounds, i. 349, 350; absorption of poisonous matter in dissection-wounds, i. 349; the most dangerous punctures those received in the examination of cases of simple or puerperal peritonitis, i. 350; consequences of dissection-wounds, i. 350; on viper-bites, and the requisite treatment, i. 353; doubts the disposition of hydrophobic patients to bite, i. 369; excision of the bitten parts in hydrophobia, i. 373; excision of the scar, i. 374; on the proximate cause of tetanus, i. 378; on the favourable termination of cases of tetanus which pass over the seventh day, i. 380; on long and free incisions on either side of the spine, and cauterizing the wounds in tetanus, i. 381; on the treatment of tetanus, i. 382; on the non-necessity for sutures in wounds of the scalp, i. 384; on bruises of the coverings of the skull, followed by collections of fluid blood, i. 384; on poultices in bruises of the scalp, i. 387; treatment of injuries of the head when inflammation of the dura mater has set in, i. 387; bleeding at the ear, a sign of fracture at the base of the cranium, i. 390; non-necessity for the trephine in general, i. 391; on fracture of the frontal sinuses, i. 392; on apparent fracture and depression of the skull, i. 392; treatment of simple fracture with depression without the trephine, i. 392; importance of caution in the prognosis of wounds of the orbit, i. 397; propriety of opening abscess of the brain, i. 399; consequences of foreign bodies remaining in the brain, i. 399; chronic inflammation of the dura mater, i. 401; mercury in the treatment of inflammation of the brain, i. 403; mercury in compression, i. 405; removal of the extravasated blood after trepanning, i. 406; puncturing the dura mater, when the extravasation lies beneath, i. 406; the operation of trepanning to remove effused blood, i. 408; state of the pulse in concussion, i. 409; treatment of concussion, i. 411; infrequency of fungus of the brain after trephining, i. 413; trepanning in caries and necrosis of the skull, i. 415; distinction between the trepan and the trephine, i. 420; operation of trephining, i. 420; trepanning the frontal sinuses, i. 422; removal of the depressed and detached bone, and of any points on the edge of the fracture. i. 422; bleeding from the middle meningeal artery, or from a sinus, i. 423; after-treatment, i. 424; the twisted suture or thin pins in wounds of the face, i. 427; wounds of the gristly passage of the ear, i. 430; on position in the treatment of wounds of the windpipe, i. 433; on the treatment of such wounds, i. 433, 434; case of fistulous wound between the thyroid and cricoid cartilages, i. 434; on secondary hæmorrhage in cut-throat, i. 434; management of fistulæ resulting from gun-shot wounds of the windpipe, with loss of substance, i. 435; examination with the probe, etc., in penetrating wounds of the chest, i. 439; condition of the lungs when the chest is opened, i. 439; on emphysema, i. 451; on the practice of sucking or pumping, to extract the air in the cavity of the chest, i. 452; case of wounded intestine, i. 462; treatment of wounded intestine without feculent discharge or prolapse, i. 471; rupture of the liver, i. 478; rupture or laceration of the bladder in fracture of the pelvis, i. 481; rupture of the perineum, i. 486; incising the spongy body of the penis, not always a cause of loss of the power of erection, i. 487; objection to amputation of the penis, in lacerations of the cavernous bodies, i. 488; treatment of rupture of the urethra, i. 488; case of hydrocele, which was tapped, and the testicle supposed to be wounded, i. 489; commends Abernethy's practice in wounds of joints, i. 490; cases of torn muscles, i. 495; causes of want of bony union in fractures of the neck of the femur, olecranon, patella, and os calcis, i. 503; non-necessity for bandages in fractures, i. 504; immoveable apparatus for fractures, i. 505; on the position of the limb when stiffness of a joint is anticipated, i. 506; after-treatment of the fracture. i. 507; impropriety of setting a fracture before the lapse of a few days; i. 507; immediate management of fractured clavicle, and of oblique fractures, i. 508; on the antiphlogistic treatment in compound fracture, i. 510; exhibition of opium in compound fracture, i. 510; enlargement of the wound, and sawing off the projecting portion of bone, i. 510; removal of splinters, i. 510; formation and treatment of abscesses during the progress of compound fractures, i. 511; treatment of wounded vessels, i. 511; mortification, and its treatment, general and local, i. 511; principal points to be considered in determining on the necessity for immediate amputation, i. 519; immediate and remote consequences of compound fracture, i. 521; sympathetic, symptomatic or irritative fever, i. 521; almost invariably subsides as suppuration is established, i. 521; occurrence of secondary, constitutional, or nervous symptoms, i. 522; amputation must not be performed while the symptomatic fever continues, i. 522; the advantages hoped for by the immediate removal of the injured parts. in preference to attempting to save them, i. 523; objects and occasional results of immediate amputation, i. 523; bending of bones, i. 526; case of extensive fracture of the bones of the face, i. 528; fracture of the lower jaw, i. 528; fracture of the os hyoides in persons who have been hung, i. 530; signs and rarity of occurrence of fracture of the spinous process of the vertebræ alone, i. 531; occurrence of fracture of the vertebræ, without any great violence, i. 532; causes of fractured vertebræ, and on the injury the spinal cord sustains from the accident, i. 533; case of separation of the under surface of the second cervical vertebra from the inter-vertebral substance, without displacement, i. 535; treatment of fracture of the spinous processes, i. 538; on the attempt to set a fracture through the body of a vertebra, i. 538; treatment of fractured spine, i. 538; operation for trepanning the spine, i. 542; after-treatment, i. 542; fracture of the coccyx, i. 543; fractures of the hip-bone, and their danger from rupture of the bladder, i. 544; diagnosis of fracture of the hip-bone, i. 544; impropriety of any operation to raise the depressed portions of bone, in fractures of the sternum, i. 546; case of wound of the heart caused by a fractured rib, i. 546; treatment of fractured ribs, i. 547; causes of fracture of the scapula, i. 548; symptoms of fracture of the acromion, i. 548; doubts the occurrence of fracture of the neck of the scapula, i. 549; case of fracture of the coracoid process, i. 549; fracture of the body, spine, and angle of the scapula, i. 549; treatment of fractured clavicle, i. 552; fracture of the greater tubercle of the humerus, i. 553; cases of fracture of the anatomical neck, i. 554; fracture of the surgical neck, i. 554; treatment of fracture of the humerus, i. 556; fracture of the condyles, i. 557; treatment of compound fracture of the humerus, i. 557; fracture of the neck of the radius, i. 558; treatment of fractures of the fore-arm, i. 560; of fractures of the olecranon. i. 561; inlocking of the broken ends of the bone, i. 564; case of separation of the head of the femur from its neck by external violence, i 565; preparation of fracture within the capsular ligament united by callus, i. 567; simple and compound fractures of the femur, i. 573; treatment of fracture of the femur, i. 573; of fractured patella, i. 578; means to be adopted for the adaptation of the rectus muscle to the new condition of the patella, i. 579; compound fracture of the patella, i. 580; treatment of fracture of the bones of the leg, i. 583; case of compound fracture of the os calcis, i. 585; fracture of the phalanges of the toes, and treatment, i. 586; causes of the non-union of fractured bones, i. 588; rubbing the ends of the broken bone together, i. 589; application of pressure in false joints. i. 590; objects to external irritation i. 590; remarks on Green's operation for an ununited fracture, i. 592; uncertainty attending all operations on false joints, i. 594; period at which the operation for hare-lip should be performed, i. 596; removal of the projecting teeth prior to the operation, i. 596; position of the child's head during the operation, i. 597; preference of the bistoury to scissors, i. 597; the time the pins should be left, and their removal, i. 599; on tearing out of the needles, i. 599; use of obturators in cleft of the hard palate, i. 600; application of strips of plaster in the treatment of ulcers, i. 619; iodide of potassium and cod-liver oil in scrofula, i. 624; treatment of sloughing chancre, i. 658; of suppurating bubo, and of the subsequent ulcer, i. 659; secondary syphilitic sores, and their treatment, i. 661; treatment of nodes, i. 662; the friction-cure, i. 664; proper mode of exhibiting mercury in the treatment of syphilis, i. 671; possibility of infection from secondary syphilis, i. 675; absorption of part of the dead bone in the process of exfoliation, i. 693; consequences of caries or necrosis in the mastoid process, i. 698; necrosis of the vault of the skull, i. 699; case of extensive destruction of the vault of the skull, i. 699; caries of the bones of the face, i. 699; disease in bones from mercury and syphilis, i. 699; inflammation and suppuration in the tooth-socket without caries, i. 701; symptoms and treatment of sympathetic disease of the antrum, i. 701; epulis, i. 702; stopping a carious tooth, i. 703; treatment of toothache, i. 704; hæmorrhage consecutive to extraction of a tooth in cases of hæmorrhagic diathesis, and its treatment by the actual cautery, i. 707; case of consecutive hæmorrhage, i. 707; necessity for adopting preventive measures immediately after the extraction of a tooth, when the hæmorrhagic diathesis is known to exist, i. 709; treatment of fistula of the parotid duct, i. 715; biliary fistulæ, i. 716; case of artificial anus at the navel, i. 722; of flow of colourless fluid from the navel, i. 722; operation for rectal fistula, i. 730; ligature of rectal fistula, i. 732; incomplete internal urinary fistula, i. 738; operation for the division of the stricture in great narrowing of the urethra, i. 747; for recto-vesical fistula, i. 748; diagnosis of dislocations i. 763; dislocations from muscular action, i. 763; reduction of dislocations, i. 765; of old dislocations, and on the necessity of caution in practising extension, i. 766; recurrence of dislocations after reduction from exhaustion of the muscular power, i. 767; auxiliary treatment in the reduction of dislocations, i. 768; reduction of dislocation of the lower jaw, i. 771; difficulty of keeping the dislocated scapular end of the clavicle reduced, i. 780; repeated dislocation of the femur in the same person, i. 795; English practice in compound dislocations of the ankle, i. 809; reducing the dislocation of the astragalus, i. 811; case of dislocation of the os calcis, i. 812; on certain forms of ruptures, ii. 2; presence of the sac in vesical and cœcal ruptures, ii. 2; causes of stricture in the body of the sac, ii. 3; hour-glass contraction of the hernial sac, ii. 4; occasional rupture of one side of the sac in femoral hernia, ii. 5; difficulty of distinguishing between intestinal and omental ruptures, ii. 8; the gurgling noise in the rupture, ii. 8; thickening of the intestine in the sac, ii. 10; incarceration and strangulation, ii. 12; costiveness as a symptom of strangulation, ii. 13; dilatation of a strangulated rupture on coughing, ii. 13; application of the taxis, ii. 15; danger attending violence in the application of the taxis, ii. 15; *reduction en masse*, ii. 15; objections to the use of tobacco enemata, ii. 30; case of mortified intestine from strangulation, ii. 32; the proper time for the performance of the operation for strangulated hernia, ii 34; objection to lifting up a fold of the skin, and incising it, ii. 35; length of the first incision in scrotal and femoral hernia, ii. 35; division of the coverings, and opening the hernial sac, ii. 36; cases of internal strangulation by bands from the mesentery or by diverticula of the ileum, ii. 37; division of the stricture, ii. 37; objections to dilatation without cutting, ii. 38; return of the intestines after the division of the stricture, ii 38; occasional effusion of fluid from the abdomen after the return of the intestines, ii. 39; treatment of adhesions between the intestine or omentum and the sac, ii. 39; objections to puncturing or incising the intestine, unless distended with solid matter, ii. 40; cases of removal of degenerated omentum, ii. 40; mode of treating the protruded omentum, ii. 41; secondary hæmorrhage from the omentum, ii. 42; dark colour of the intestine caused by venous congestion, ii. 42; consequences of protracted constriction of the intestine, and of violence in the application of the taxis, ii. 45; signs indicative of gangrene of the intestine, ii. 45; case of gangrenous intestine, in which a fetid smell was perceptible before the sac was opened, ii. 46; division of the stricture external to the sac, ii. 47; treatment after the operation, ii. 47; suppuration of the sac, ii. 49; case of extensive sloughing of the abdominal and lumbar cellular tissue after the operation, ii. 49; occurrence of gangrene in the intestine some days after the operation in persons of an enfeebled constitution, ii. 50; description of the fascia transversalis, ii. 55; coverings of imperfect inguinal rupture, ii. 57; difficulty of diagnosis between rupture and hydrocele of the cord, ii, 60; cases of hydrocele of the cord mistaken for rupture, ii. 60; direction of the cut in dividing the stricture in inguinal rupture, ii. 64; anatomy of femoral rupture, ii. 67; diagnosis of femoral from inguinal rupture in women, ii. 70; presence of other tumors in the femoral region likely to be mistaken for femoral rupture, ii. 70; coverings of femoral rupture, ii. 70; cases of femoral rupture with two sacs, ii. 75; ligature of the umbilical cord, ii. 79; case of double umbilical rupture, ii. 80; opposed to the radical cure of umbilical rupture by ligature, ii. 83; cases of rupture of the linea alba, ii. 84; cerebral rupture, ii. 97; accidental cerebral rupture, ii. 100; irritation of the rectum in prolapsus uteri, ii. 105; contents of the sac formed by the prolapsed vagina, ii. 105; case of prolapse of the bladder relieved by operation, ii. 126; treatment of prolapse of the rectum in children, ii. 132; causes of high shoulder, ii. 159; case of hysterical club foot, ii. 177; cases of club foot from palsy of the muscles of the leg, ii. 179; treatment of club foot in early infancy, ii. 180; section of the tendo Achillis in club foot, ii. 182; application of the extending power after the operation and healing of the wound, ii. 183; division of the plantar fascia ii. 184; section of the tendon of the tibialis posticus, and danger of wounding the posterior tibial artery, ii. 184; cause of the mischief in splay foot, ii. 187; ulceration of the calf a cause of horse foot, ii. 189; case of horse foot from palsy, ii. 189; apparatus for horse foot, ii. 189; distinguishing characters of circumscribed true and false aneurism, ii. 201; case of aneurism mistaken for abscess, ii. 202; relative frequency of aneurism in the sexes, ii. 203; spontaneous cure of aneurism, ii. 206; size of the aneurism best fitted for operation, ii. 217; importance of opening the sheath to the least possible extent in applying a ligature round an artery, ii. 221; return of pulsation in the aneurism for a short time, after the ligature of the artery, ii. 223; treatment of secondary hæmorrhage, ii. 225; objections to the operations for ligatures of the axillary artery, ii. 241; ligature of the subclavian, ii. 243; aneurisms of the aorta and origin of the carotid and subclavian liable to be mistaken for aneurism of the subclavian, ii. 245; results of injury to the axillary nerves, ii. 249; compensating collateral branches after ligature of the brachial, ii. 254; comments on Perry's case of aneurism bursting into a vein, ii. 272; application of the ligature in teleangiectasy, ii. 283; caustic in teleangiectasy, ii. 284; case of varix of a deep-seated vein, ii. 289; ligature of the saphena vein for varix, ii. 291; spermatocele, ii. 295; adhesion of the tongue to the cheek, ii. 315; objections to protrusion of the tongue prior to the passage of the œsophagus bougie, ii. 323; case of adhesion of the two portions of the ileo-colic valve, causing obstruction to the passage of the meconium, ii. 326; of imperforate anus opening under the glans penis, ii. 329; Jewish operation of circumcision, ii. 345; reduction of paraphimosis, ii. 350; danger of using plaster bougies in stricture, ii. 361; introduction of the bougie, ii. 362; general treatment of stricture, ii. 363; practice to be adopted when laceration of the urethra by the bougie is suspected, ii. 365; use of the armed bougie, ii. 372; treatment of false passages, ii. 373; of closure of the vagina in infants, ii. 375; case of a piece of tobacco-pipe lodged in the cheek, ii. 380; cases of foreign bodies in the œsophagus, ii. 381; case of a fish-bone in the œsophagus, ii. 382; preference of tracheotomy to œsophagotomy, ii. 385; inserting a tube in the larynx after laryngotomy, ii. 400; case of fistulous opening in the larynx after an attempt at suicide, ii. 400; necessity of probing the larynx and rima glottidis after an operation for the extraction of foreign bodies, ii. 403; mode of operating for ranula, ii 407; case of adhesion between, and ulceration of the gall-bladder into the duodenum, ii. 408; bursting and gangrene of the bladder, rare terminations of ischuria, ii. 411; rare occurrence of re-opening of the urachus, ii. 412; obstruction to the urine by calculi in the urethra, ii. 416; removal of calculi from the urethra, ii. 418; case of retention of urine from the pressure of an hydatid, ii. 419; catheterism in inflammation of the prostate, ii. 420; in enlarged prostate, ii. 425; treatment of complete retention in stricture, ii. 425; operation of cutting into the urethra in the perineum, ii. 428; shape and thickness of the catheter, ii. 430; puncturing the bladder, ii. 436; hæmatocele following the operation for hydrocele, ii. 456; dispersing the blood in hæmatocele of the vaginal tunic, ii 456; occurrence of suppuration if the effused blood be not soon absorbed, ii. 457; formation of bursæ from pressure, ii. 458; partial enlargements of the sheaths of tendons, ii. 459; *housemaid's knee*, ii. 459; treatment of dropsical bursæ, ii. 461; objection to operating in hydrarthrus, ii. 462; objects to injections of iodine in hydrarthrus, ii. 462; to opening abscess of the lung, ii. 475; suppuration of the pericardium, ii. 479; propriety of passing the catheter before tapping for dropsy, ii. 484; of ascertaining the condition of the womb before tapping, ii. 484; operation of tapping, ii. 484; case of wound of the epigastric artery in tapping, ii. 485; of venous hæmorrhage during tapping, ii.

485 ; relative value of the small and large operations for ovarian dropsy, ii. 490 ; characters of hydrocele, ii. 497. situation of the testicle in hydrocele, ii. 498 ; characters of the serum in hydrocele, ii. 498 ; complications of hydrocele, ii. 498 ; the spontaneous cure of, ii. 499 ; treatment of by punctures, ii. 500 ; impropriety of any other operation than tapping in hydrocele of old people, ii. 501 ; iodine injection in hydrocele, ii. 504 ; suppuration of the tunica vaginalis after the operation by injection, ii. 504 ; treatment when the cellular tissue of the scrotum is injected by mistake instead of the tunica vaginalis, ii. 504 ; of hydrocele by seton, ii. 505 ; cutting away the vaginal tunic, ii. 506 ; treatment of hydrocele complicated with rupture, ii. 511 ; foreign bodies the nuclei of stones, ii. 524 ; treatment of renal calculi, ii, 542 ; sounding, ii. 550 ; existence of calculous symptoms without the presence of a stone in the bladder, ii. 551 ; simulation of calculus by vesical polypus, ii. 551 ; measuring the calculus. ii. 551 ; case of stone undetected by the sound during eight years, ii. 581 ; external incision in lithotomy, ii. 582 ; use of the cutting gorget, ii. 593 ; contraction of the bladder during lithotomy, ii. 600 ; treatment of hæmorrhage during and after the operation for stone, ii. 603 ; secondary hæmorrhage, ii. 604 ; case of secondary hæmorrhage, ii. 604 ; wounding the rectum, ii. 606 ; treatment to be adopted after the operation, ii. 607 ; incontinence of urine consequent on lithotomy in women, ii, 622 ; dilatation of the female urethra for the extraction of calculi, ii, 622 ; cases in which lithotrity should be performed, and those in which lithotomy should be preferred, ii. 628 ; treatment of stone in the urethra, ii. 631 ; extraction of calculi in the urethra in front of the scrotum, without incising the canal, ii. 632 ; lymphatic bronchocele and serous cysts in the neck, ii. 654 ; employment of iodide of potassium, ii. 661 ; in the form of ointment, ii. 662 ; enlargement of the nymphæ, ii. 665 ; removal of the enlarged nymphæ by operation, ii. 666 ; venereal and malignant warts, ii. 666 ; treatment of common, venereal, and malignant warts, ii. 667 ; case of human horns, ii. 670 ; fatty tumours, ii. 690 ; lipoma diffusum, ii. 690 ; extirpation of fatty tumours, ii. 693 ; removal of the roots of the tumour, and after-dressing, ii. 694 ; cysts forming around foreign substances, ii. 694 ; atheromatous cysts, and their contents, ii. 696 ; cause of sebaceous tumours, ii. 698 ; removal of by operation, ii. 701 ; condemns the extirpation of ganglions, ii. 703 ; cases of acephalocysts, ii. 704 ; composition of foreign bodies in joints, ii. 708 ; mode of operating for foreign bodies in joints, ii. 709 ; two kinds of sarcomatous tumours, ii. 710 ; enlargement of the prepuce and scrotum, ii. 711 ; removal of sarcomatous tumours by operation, ii. 712 ; plugging the nostrils, ii. 734 ; opening the maxillary sinus, ii. 742 ; after-treatment, ii. 743 ; tumours of nerves in stumps, ii. 765 ; case of long-standing scirrhus, ii. 768 ; compression of scirrhus, ii. 770 ; operation for cancer of the lip, when the disease does not extend beyond the red part, ii. 774 ; scirrhus of the breast, ii. 784 ; case of lacteal swelling, ii. 789 ; question as to the propriety of removing a scirrhous breast, ii. 796 ; case of fatal venous hæmorrhage from extirpation of the breast, ii. 798 ; after-treatment, ii. 798 ; opinion that amputation is not preferable to extirpation of the breast, ii. 799 ; recurrence of cancer after amputation of the penis, ii. 801 ; relative value of the two operations for amputation of the penis, ii. 803 ; retraction of the cord during extirpation of the testicle, ii. 812 ; ligature of the spermatic cord, ii. 813 ; treatment of undescended testicle, ii. 814 ; extension of chimney-sweep's cancer to the neighbouring parts, ii. 816 ; cause of chimney-sweep's cancer, ii. 816 ; case of recurrence of the disease after its extirpation, ii. 816 ; case of reunion of divided parts, ii. 835 ; exhibition of opium and dietetic stimulants prior to and after an operation, ii. 854 ; condemns Wardrop's proposal to bleed a patient to fainting, and operate during the syncope, ii. 855 ; directions for blood-letting from a vein, ii. 862 ; arteriotomy, ii. 864 ; treatment of the after-bleeding from leech-bites, ii. 866 ; substitute for cupping, ii. 868 ; dangerous hæmorrhage from cupping, ii. 868 ; relative value of leeches and cupping, ii. 868 ; preference of cupping, ii. 868 ; use of glass beads for issues, ii. 869 ; of India rubber tape for setons, ii. 870 ; application of blisters, ii. 871 ; inconveniences resulting from keeping a blister too long on the part, ii. 871 ; on the length of time during which a blister should be applied, ii. 871 ; on children, ii. 871 ; use of mustard poultices, ii. 872 ; vesicating by friction with croton oil, ii. 872 ; relative value of the tourniquet, and of compression of the principal artery by a capable assistant in amputation, ii. 889 ; retraction of the divided muscles by the hand in amputation, ii. 893 ; use of the saw, ii. 893 ; duties of the assistant when the bone is being sawn through, ii. 894 ; venous hæmorrhage, and the ligature of the veins after amputation, ii. 894 ; exposure of the stump, ii.

895; bringing the edges of the wound together in the horizontal direction, ii. 896; application of the strips of plaster after amputation, ii. 896; use of cradles, and a substitute for them, after amputation, ii. 897; of sutures after flap-amputations, ii. 897; objects to the practice of dressing the amputation-wound to heal by suppuration and granulation, ii. 897; treatment of ligatures after amputation, ii. 898; of after-bleeding, ii. 899; impropriety of tying the main arterial trunk for consecutive hæmorrhage after amputation, ii. 899; use of the actual cautery in after-bleeding, ii. 899; causes and treatment of protrusion of the bone, ii. 901; exfoliation of the bone after amputation, ii. 901; fungous growth from the medullary cavity, ii. 901; relative value of the flap and circular operations, ii. 903; objects to flap operations on the leg, ii. 903; union of an amputation-wound, ii. 904; results of amputation, ii. 905; position of the limb in amputation of the thigh, ii. 906; position and duties of the assistants, ii. 906; circular cut, and vertical division of the skin laterally, ii. 907; mode of using the knife in amputating, ii. 908; retraction of the soft parts with the hand while sawing through the bone, ii. 908; bandaging and dressing the wound, ii. 908; reason why in Liston's flap-operation the hind flap should be longer than the front, ii. 909; comments on Syme's objections to amputation through the shaft of the femur, and recommendation to amputate through the trochanters, or condyles, ii. 910; formation of conical stumps in flap-amputations of the thigh, ii. 914; application of the tourniquet in amputations of the leg. ii. 916; seat of amputation through the leg, ii. 917; ligature of the retracted anterior tibial artery in amputation high up through the leg, ii. 918; treatment of hæmorrhage from the nutritious artery of the tibia, ii. 918; causes of subsequent sloughing of the integuments, ii. 918; objections to flap amputations of the leg, ii. 919; case of amputation just above the ancle, ii. 922; tabular report of amputations through the leg, ii. 922; propriety of having a long stump, if possible, in amputation through the upper arm, ii. 923; tabular report of, ii. 925; flap-amputations through the fore-arm, ii. 926; tabular report of, ii. 927; consequences of amputation through the metatarsal bone of the great toe, ii. 929; amputation through the metacarpal bones, ii. 930; amputation at the hip-joint, ii. 933; excision of the acromion, glenoid cavity, and coracoid process in amputation at the shoulder-joint, ii. 961; case of amputation at the shoulder-joint, ii. 961; precautions to be taken in the flap-operations at the wrist, ii. 963; comparative danger of primary and secondary amputation in severe injuries of the thigh, ii. 967; conclusion in favour of primary amputation, ii. 967; minor danger in injuries of the leg or upper extremities, and consequent propriety of immediate amputation, ii. 967; excision of the ancle-joint, ii. 984; injurious effects produced by the inhalation of ether, ii. 1008; impropriety of inhaling ether prior to the operation for cataract, ii. 1009.

SOUTHAM on paracentesis in ovarian dropsy, ii. 488; nature of ovarian disease, ii. 491; extirpation of ovarian cysts, ii. 493.

SPENCE on the effects of the scorpion sting, i. 351.

Spermatic artery, ligature of, ii. 811.

—— cord, wounds of, 488; degeneration of, ii. 812.

Spermatocele, ii. 295.

SPEYER on the peculiar causes of death at different periods in wounds of the heart, i. 454.

Spina bifida, ii. 464; ventosa, ii. 678.

Spine, fracture and dislocations of, i. 531, 772; curvatures of, ii. 157.

Splay-foot, ii. 185.

SPLEEN, WOUNDS OF THE, i. 479; are generally fatal, i. 479; Astley Cooper's case of wound of, i. 479; Astley Cooper's cases of separation of from its attachments, i. 480; rupture of, i. 480; protrusion of, i. 480; Ferguson's case, i. 480.

STANLEY on inversion of the foot in fracture of the neck of the femur, i. 565; case of fracture of the neck of the femur within the capsular ligament united by bone, i. 567; of dislocation of the astragalus outwards, i. 810; of contracted knees cured by the subcutaneous section of the hamstring tendons, ii. 174; pulsating tumors of bones, ii. 277.

Staphyloraphy, i. 602—607.

STARK's case of wound of the larynx and pharynx, i. 435.

STARKE on the phosphor. hydrarg. in the treatment of syphilis, i. 662.

Steno's duct, fistula of, i. 712.

Sternum, fracture of, i. 545.

STEVENS', Dr., operation for the ligature of the internal iliac, ii. 257.

STEWART's opinions relative to the formation of pus, i. 35.

STIEBEL's diagnostic sign for vertebral caries, i. 281.

STILLING on the interweaving of arteries, i. 311.

STOKES', Dr. case of displacement of the heart from external violence, ii. 96; cases of foreign bodies in the œsophagus inducing laryngeal symptoms, ii. 398.

Stoess on the section of the tendo Achillis in club-foot, ii. 182.

Stomach, wounds of the, i. 475; symptoms, i. 475; danger of such wounds, i. 475; treatment, i. 475; use of the suture if the external wound be large, the wound of the stomach directly opposite, or if the wounded part protrude, i. 475; Scott's case of wounded stomach without protrusion, i. 475; Travers' case in which he applied a ligature round the wound of a protruded stomach, i. 476; Dr. Cook's case of fistulous opening in the stomach, i. 477; foreign bodies in the, ii. 388.

Stricture of the œsophagus, ii. 317; of the rectum, ii. 324; of the urethra, ii. 351.

Stromeyer on the causes of congenital dislocations, i. 769; of wry neck, ii. 153; treatment of wry neck after the section of the sterno-cleido-mastoideus, ii. 156; palsy of the serratus magnus a cause of scoliosis or lateral curvature of the spine, ii. 161; case of curvature of the hip, in which the pectineus and sartorius were divided, ii. 172; section of the tendo Achillis in club-foot, ii. 182; causes of splay-foot, ii. 186; treatment of aneurismal varix, ii. 271.

Struve on extirpation of the wound, ii. 823.

Subclavian aneurism, ii. 240.

—— artery, ligature of, ii. 242.

Sue's case of a foreign body remaining a long while in the windpipe, ii. 396.

Suppuration:—a natural result of severe inflammation, i. 34; secretion of pus, i. 34; formation of abscess, i. 34, 36; opinions of Simpson, De Haen, Morgan, Hunter, Brugmans, Pinel, Boerhaave, Bell, Gotter, Quesnay, Hoffman, Grashuis, Stewart, Pearson, Hewson, E. Home, Berzelius, Gruithuisen, Fischer, Donné, Gluge, Valentin, Gueterbock, Wood, Bonnet, Mandt, Vogel, and von Bibra, relative to the formation of pus, i. 35; symptoms of approaching suppuration, i. 35; occurrence and signs of fluctuation, i. 36; symptoms of deep-seated suppuration, i. 36; hectic fever accompanies every considerable suppuration, i. 36; formation of the walls of an abscess, and circumscription of the pus, i. 36; circumscription of pus does not take place unless the inflammation be connected with plastic exudation, i. 36; walls of an abscess are secreting and absorbing surfaces, i. 36; resorption of pus, i. 36; metastatic abscesses, i. 36; Vogel and Bonnet on the effects of the resorption of pus, i. 36; Hunter on the cause and results of suppuration, i. 36; Valentin on the microscopic results of suppuration, i. 37; Hunter on suppurative inflammation, i. 37; Travers on the lining membrane of an abscess, i. 38; Hunter and Travers on the circumstances which determine an abscess to the surface, i. 38; qualities of pure good pus, i. 38; formation of pus, i. 39; Travers on the purpose which the formation of pus serves in the economy, i. 39; Hunter on the qualities of pus and the pus-globules, i. 39; Hunter and Gulliver on the putrefaction of pus, i. 39; Senac on the globular structure of pus, i. 39; Gueterbock on the composition and chemical analysis of pus, i. 40, 41; composition of the serum of pus, i. 40; fatty vesicles discovered by Henle in the serum of pus, i. 40; Gueterbock's discovery of pyine, i. 40; characters of pus-globules, i. 40; Mandt on the pus-globules, i. 40; discovery of the difference in size of the pus-globules, i. 41; Mayo describes pus-globules as occasionally seen in healthy blood, i. 41; denied by Gulliver, i. 41; Gerber's account of the formation of pus, and of the reproductive organization in suppurating wounds, i. 41; Travers on the constitution of pus, i. 42; varieties of pus, i. 43; distinguishing characters of laudable pus, and ichor or sanies, i. 43; presence of globules in the serum proved by Bauer, Faraday, and Mandt, i. 43; characters of the albumen in pus, i. 44; Grassmeyer and Fischer on the distinguishing tests for pus and mucus, i. 44; Gruithuisen's microscopic tests for pus and mucus, i. 44; Gerber's description of ichor, puriform mucus, and serous exudations, i. 44; pus cannot be produced without inflammation, i. 44; cold or lymph abscess, i. 45; the diathesis purulenta, i. 45; abscess of congestion, i. 45; symptoms of cold abscess, i. 45; cold abscess not to be confounded with Hunter's collections of matter without inflammation, nor with the cold abscess of the surgeons of the Saracen school, the chronic abscess of modern surgeons, i. 45; South's case of cold abscess, i. 45; Dr. Rigby on puerperal abscess following contagious or adynamic puerperal fever, i. 47; Beinl, Rust, and others regard the so-called lymph-swelling as being an extravasation of lymph, i. 48; Beinl's opinion that the strongest and most healthy are more subject to lymph-abscess than the weak, and men than women, and that it does not occur without external injury disproved by Rust, i. 48; Nasse's case of lymph-swelling from external injury, i. 48; such cases exceedingly rare, i. 48; opinions of Langenbeck, Ekl, and Zembsch on the lymph-swelling, i. 48; South's case of lymph-abscess, i. 49; treatment during and after suppuration, i. 87; attention to the general health requisite during suppuration, i. 93; suppuration of the testicle to be feared when the inflammation is active and the pain throbbing, i. 179; suppuration of the testicle rare when the swelling is sympathetic, i. 180; Astley Cooper on suppuration of the testicle, i. 180; bursting of the abscess sometimes followed by a fungous growth, i. 180; treatment of suppuration and abscess of the testicle, i. 181; treatment of suppuration external to the joints, i. 209; of suppuration internal to the joints, i. 209; South's cases of abscesses external to the joint, i. 210; suppuration of the synovial membrane, i. 214; symptoms of suppuration of the hip-joint, i. 251; Astley Cooper and Coulson on the bursting of abscesses of the hip-joint, i. 253; Mackenzie and Scott's cases of abscesses of the hip-joint, i. 254; Key and South on suppuration of the sac, after the operation for strangulated hernia, ii. 49.

Surgery, definition of, i. 1; division of, i. 3; historical sketch of, i. 5; literature of, i. 9.

SURGICAL OPERATIONS:—elementary proceedings, ii. 852; steps of an operation, ii. 852; method of operating, ii. 852; circumstances to be attended to in giving the preference to the various methods of operating, ii. 852; many operations subject to certain and general rules, ii. 852; those operations most difficult which are not subject to rules, ii. 853; cases requiring operations, ii. 853; circumstances necessary to be attended to in order to obtain the successful result of the operation, ii. 853; the patient's condition relative to the success of the operation ii. 853; proceedings preparatory to an operation, ii. 854; South on the exhibition of opium and dietetic stimulants prior to, and after an operation, ii. 854; time of the year at which operations should be performed, ii. 855; Wardrop's proposal to bleed the patient to fainting, and operate during the syncope, ii. 855; condemned by South, ii. 855; the most serious occurrences during an operation, ii. 855; faintings and convulsions, ii. 856; sudden death and its causes during operations, ii. 856; entrance of air into veins, ii. 856; treatment of such an accident, according to Amussat and Magendie, ii. 856; Bichat, Nysten, Magendie, and Piedagnel on the cause of death from the entrance of air into the veins, ii. 856; Amussat, Warren, Mussey, and Mercier on the treatment of the accident, ii. 856; B. Cooper's case, ii, 856; *division of organized parts*, ii. 857; by mechanical or chemical means, ii. 857; four modes of effecting division by mechanical means, ii. 857; two classes of instruments for the division of soft parts by cutting, ii. 857; knives, bistouries, and scalpels, ii. 857; varieties of the bistoury, ii. 857; description of a regular cut, and mode of making it, ii. 857; varieties of incisions, ii. 858; use of the convex and button-ended bistoury, ii. 858; mode of holding the knife, ii. 858; mode of action of scissors in effecting the division of parts, ii. 858; circumstances under which scissors are used, ii. 859; varieties of scissors, ii. 859; mode of using scissors, ii. 859; division of soft parts by stabbing, ii. 859; instruments used for that purpose, ii. 859; description of the trocar and lancet, ii. 859; division of parts by tearing, ii. 859; specially used for polypi, ii. 859; division of parts by tying or the ligature, ii. 860; cases in which this mode of division should be employed, ii. 860; division of a bone, ii. 860; instruments used for the purpose, ii. 860; *separation of divided parts*, ii. 860; *dilatation of parts*, ii. 860; *general surgical operations*, ii. 860; *blood letting*, ii. 860; modes of operating, ii. 860; *opening veins, phlebotomy*, ii. 860; situation where performed, ii. 861; choice of a vein at the bend of the elbow, ii. 861; mode of opening a vein, ii. 861; South's directions for blood letting from a vein, ii. 862; dressing the wound, and applying the bandage, ii. 862; accidents which occur during the operation, ii. 862; faulty stab, ii. 862; formation of too small an opening, ii. 862; stoppage of the flow of blood, ii. 862; severe pain from wounding a nerve, ii. 862; wounding an artery, ii. 862; wound of a lymphatic vessel, tendon, or aponeurotic expansion, ii. 862; accidents which may occur after the operation, ii. 863; bleeding, ii. 863; inflammation and suppuration, ii. 863; inflammation of the veins or lymphatics, ii. 863; Abernethy on the treatment of traumatic phlebitis, ii. 863; severe pain and even convulsions from partial division of a nervous twig, ii. 863; Abernethy on the complete section of the nervous twig in such cases, ii. 863; use of the snapper dangerous, ii. 863; opening the veins of the fore-arm and hand, ii. 863; blood-letting in the foot, ii. 863; blood-letting in the neck, ii. 863; directions for opening the external jugular vein, ii. 863; *opening arteries*, ii. 864; only performed on the temporal, ii. 864; mode of operating, ii. 864; South and Cline jun. on arteriotomy, ii. 864; *application of leeches*, ii. 864; mode of applying them, ii. 864; description of the blood-leech, ii. 864; of the horse-leech and common leech, ii. 865; means to induce leeches to bite, ii. 865; application of leeches to the mouth, or near the anus, ii. 865; Crampton and Osborne on the

application of leeches to the mucous surfaces, ii. 865; treatment after the leeches have dropped off, ii. 865; of the after-bleeding in children, ii. 865; Bricheteau, Lisfranc, Green, and Oliver's cases of fatal hæmorrhage from leech-bites, ii. 866; South on the treatment of the after-bleeding, ii. 866; treatment of ecchymosis, inflammation and suppuration of leech-bites, ii. 867; *scarification*, ii. 867; definition and employment of, ii. 867; *cupping*, ii. 867; mode of operating, ii. 867; dry cupping, ii. 868; South on a substitute for cupping, ii. 868; Dr. Osborne's polytome, ii. 868; South on dangerous hæmorrhage from cupping, ii. 868; relative value of leeches and cupping, ii. 868; Junod's apparatus to cause derivation of blood, ii. 868; South on the relative value of leeches and cupping, ii 868; South's preference of cupping, ii. 868. *putting in issues*, ii. 869; definition, ii. 869; situation in which issues should be made, ii. 869; making an issue with the bistoury, ii. 869; South on the use of glass beads for issues, ii. 869; making an issue by a blister, ii. 869; after-treatment of the issue, ii. 869; *introducing a seton*, ii. 870; definition, ii. 870; mode of operating, ii. 870; South on the use of India-rubber tape for setons, ii. 870; passing a seton into a cavity containing fluid, ii. 870: into a swelling not containing fluid, ii. 870; after-treatment of the seton, ii. 870; *application of blister plaster and mezereon bark*, ii. 871; mode of application of blister plaster, ii. 871; South on the application of blisters, ii. 871; blisters raised by boiling water, ii. 871; South on the inconveniences resulting from keeping a blister too long on the part, ii. 871; South on the length of time during which a blister should be applied, ii. 871; on children, ii. 871; South on the use of mustard poultices, ii. 872; treatment of the blister, ii. 872; treatment of severe inflammation from a blister, ii. 872; of strangury, ii. 872; employment of mezereon bark as a blister, ii. 872; South on vesicating by friction with croton oil, ii. 872; *vaccination or inoculation with cow pock*, ii. 873; definition, ii. 873; use of the lymph, ii. 873; Dr. Gregory on the origin of vaccination, ii 873; Dr. Jenner's discovery, ii. 873; Cline the first experimenter, ii. 873; Dr. Gregory on the preservation of vaccine lymph for transmission, ii. 874; Gregory on the period at which lymph should be taken for vaccination, ii. 874; vaccination an operation without danger, ii. 874; mode of vaccinating from a fresh pustule, ii. 874; Dr. Gregory on the operation of vaccination, ii. 874; vaccination with dry matter, ii. 874; appearances after effectual vaccination, ii. 874; Gregory on the appearances after effectual vaccination, ii. 875; irregularities in the course of the vaccine vesicle, ii. 875; Gregory on the insusceptibility of some constitutions to the vaccine virus, ii. 876; after-treatment, ii. 876; Gregory on the appearance of vaccine lichen, ii, 876; *infusion and transfusion*, ii. 876; definition and use of infusion, ii. 877; effects of infusion, ii. 877; of simple warm water used by Magendie in hydrophobia, ii. 877; use of infusion in tetanus, cholera, and foreign bodies in the throat, ii. 878; mode of operating, ii. 878; definition of transfusion, ii. 878; cases in which it is applicable, ii. 878; immediate and mediate transfusion, ii. 879; apparatus and operation for immediate transfusion, ii. 879; possible dangers of transfusion, ii. 879; mode of operating in mediate transfusion, ii. 880; Blundell's apparatus, ii. 880; Müller's proposal to separate the fibrous parts of the blood prior to transfusion, ii. 880; *cauterization*, ii. 880; employment of escharotics, ii. 881; of fire by the actual cautery and by moxas, ii. 881; the object of cauterization, ii. 881; the effect of cauterization by escharotics and by fire, ii. 881; various degrees of heat at which the actual cautery is applied, ii. 881; the various forms of cautery irons, ii. 881; application of the actual cautery, ii. 882; parts to which the actual cautery should not be applied, ii. 882; after-treatment, ii. 882; description and application of the moxa, ii. 882; Larrey's moxa of rotten phosphorescent wood, ii. 882; Percy's moxa made with the pith of the sun-flower, ii. 883; moxas made with English blotting-paper and chromate of potash, ii. 883; treatment of the slough from a moxa, ii. 883; difference between the effect of a moxa and of the actual cautery, ii. 883; *division of nerves in neuralgia*, ii. 883; cases in which the operation is required, ii. 884; the result of the operation doubtful, ii. 884; excision of a portion of the nerve, and cauterization recommended, when the disease returns after the section, ii. 884; subcutaneous division of nerves, ii. 884; symptoms of frontal neuralgia, ii. 884; division of the nerve and subsequent treatment, ii. 884; the operation for the subcutaneous division of the inner and outer branches of the frontal nerve, ii. 884; the operation for infra-orbitar neuralgia, ii. 884; the operation for the subcutaneous division of the infra-orbitar nerve, ii. 884; Klein's operation for the division of the middle branches of the facial and of the infra-orbitar nerves, ii. 884; Klein's operation

for dividing the facial nerve, ii. 885; Klein's operation for dividing the inferior maxillary nerve, ii. 885; Dieffenbach's operation for the subcutaneous division of the nerves of the cheek, ii. 885; Bonnet's operation for the subcutaneous division of the nerve in mental neuralgia, ii. 885; Klein's operation for destroying the trunk of the facial nerve at its exit from the stylo-mastoid foramen, ii. 885; the operation performed in two cases, without a permanent cure, ii. 886; Klein considers the operation to be entirely free from danger, ii. 886; Langenbeck's operation for the division or excision of the facial nerve at the stylo-mastoid foramen, ii. 886; comparison of the subcutaneous division of nerves with the ordinary operation, ii. 886; Bonnet on the nature of the uniting medium between the two ends of the divided nerve, ii. 886; Delpech, Earle, Astley Cooper, Abernethy, Wilson, Malagodi, Swan, Manovy, and Bujalsky's cases of nerves divided for neuralgia, ii. 887; Lentin on neuralgia of the heel, ii. 887; *amputation of the limbs*, ii. 887; amputations divided into those which are performed in the continuity of limbs and those at joints, ii. 888; points to be considered in performing amputations, ii. 888; precautions against hæmorrhage, ii. 889; inconveniences of the application of the tourniquet, ii. 889; compression of the principal artery by a capable assistant preferable, ii. 889; Brünninghausen's recommendation to swathe the limb in flannel, to diminish the loss of blood, ii. 889; South on the relative value of the tourniquet, and of compression of the principal artery by a capable assistant in amputation, ii. 889; formation of such wound that the bone can be properly covered by soft parts, ii. 890; by the circular incision, ii. 890; the Celsian operation, ii. 890; objections to this operation, ii. 890; Petit, Mynors, Brünninghausen, Louis, Alanson, Gooch, Bell, Desault, Richter, Boyer, Graefe, Dupuytren, Wilhelm, Valentin, and Portal's modes of operating, ii. 890; flap amputations, ii. 891; Pott, Siebold, and Schreiner's operations, ii. 892; Langenbeck and Scoutetten's operations for disarticulations, ii. 892; the oblique cut of Sedillot and Baudens, ii. 892; the sloping cut of Blasius, ii. 892; retraction of the divided muscles and sawing of the bone, ii. 893; scraping off the periosteum superfluous, ii. 893; Walther and Brünninghausen's management of the periosteum, ii. 893; South on the retraction of the divided muscles by the hand, ii. 893; South and Liston on the use of the saw, ii. 893; South on the duties of the assistant, when the bone is being sawn through, ii. 894; ligature of the divided vessels, ii. 894; historical sketch of the treatment of hæmorrhage after amputation, ii. 894; South on venous hæmorrhage, and the ligature of the veins after amputation, ii. 894; subsequent dressing of the wound, ii. 895; leaving the wound open for some hours after the operation, to guard against after-bleeding, ii. 895; Dupuytren's practice, ii. 895; South on the exposure of the stump, ii. 895; mode of dressing to promote quick union, ii. 895; South on the bringing the edges of the wound together in the horizontal direction, ii. 896; South on the application of the plaster straps after amputation, ii. 896; use of cradles after amputation, ii. 897; South on the use of cradles, and of a substitute for them, after amputation, ii. 897; dressing after flap-amputations, ii. 897; South on the use of sutures after flap-amputations, ii. 897; dressing the stump, when intended to heal by suppuration and granulation, ii. 897; South's objections to the practice, ii. 897; accidents which may ensue after amputation, ii. 897; renewal of the dressing under ordinary circumstances, ii. 897; mode of changing the dressings, ii. 898; withdrawal of the ligature, ii. 898; general treatment after amputation, ii. 898; Benedict's stimulant treatment of stumps, ii. 898; South on the treatment of ligatures after amputation, ii. 898; after-bleeding, and its treatment, ii. 898; ligature of the principal arterial trunk for consecutive hæmorrhage, ii. 898; causes and treatment of parenchymatous bleeding, ii. 899; treatment of consecutive hæmorrhage, from ossification or cartilaginous thickening of the arteries, ii. 899; South on the treatment of after-bleeding, ii. 899; South on the impropriety of tying the main arterial trunk for consecutive hæmorrhage after amputation, ii. 899; South on the use of the actual cautery in after-bleeding, ii. 899; violent inflammation of the stump, and its treatment, ii. 899; erythetic condition of the stump, ii. 899; inflammation of the arteries or veins, a not infrequent cause of death after amputation, ii. 900; symptoms and treatment, ii. 900; insufficient degree of inflammation, or torpid condition of the stump, ii. 900; treatment of sloughing, ii. 900; of too copious suppuration, ii. 900; causes and treatment of protrusion of the bone, ii. 900; South on the causes and treatment of protrusion of the bone, ii. 901; necrosis of the bone, ii. 901; South on the exfoliation of bone after amputation, ii. 901; ulceration of the bone or soft parts, ii. 901; South on the fungous growth

from the medullary cavity, ii. 901; the relative value of the several modes of proceeding in amputation of the limbs in their continuity, ii. 901; objections to the flap-operation, ii. 902; cases in which the flap-operation is suitable, ii. 902; Liston's preference of the flap-operation, and objections to the circular operation, ii. 902; South and Fergusson on the relative value of the flap and circular operations, ii. 903; Fergusson on amputation through the calf of the leg and at the shoulder-joint, ii. 903; South's objections to flap-operations on the leg, ii. 903; the propriety of quick union of stumps, or of the cure by suppuration and granulation, ii. 904; Dupuytren's mode of dressing stumps, ii. 904; South on the union of an amputation-wound, ii. 904; *results of amputation*, ii. 905; Phillips, Lawrie, Potter, and South on the results of amputation, ii. 905. *Amputation in the continuity of the several limbs:—amputation through the thigh*, ii. 906; preparatory steps of the operation, ii. 906; compression of the artery, ii. 906; South on the position of the limb, ii. 906; South on the position and duties of the assistants, ii. 906; the circular operation, ii. 907; division and retraction of the skin and cellular tissue, ii. 907; South on the circular cut and vertical division of the skin laterally, ii. 907; section of the muscles, ii. 907; of the periosteum, ii. 907; sawing the bone, ii. 907; cutting through the muscles on the outside of the thigh, ii. 907; South on the mode of using the knife in amputating, ii. 908; South on the retraction of the soft parts with the hand, while sawing through the bone, ii. 908; bandaging and dressing the wound, ii. 908; South on bandaging and dressing the wound, ii. 908; *amputation through the thigh, with two flaps*, ii. 908; mode of operating, ii. 908; Langenbeck's mode of amputating, ii. 908; Liston's mode of amputating the thigh by the flap-operation, ii. 909; preferred by Syme and Fergusson, ii. 909; Fergusson and South's reasons why the hind flap should be longer than the front, ii. 909; *amputation through the thigh with a single flap*, ii. 909; Benedict, Textor, and Jaeger's plan of amputating with a flap from the outer side, ii. 909; Zang and Textor's plan with a flap from the inner side, ii. 909; Hey's mode with the flap from behind, ii. 909; B. Bell, Le Gras, and Foulliay's plan with a flap from before, ii. 909; mode of operating, ii. 909; Dr. Little's case of amputation with a flap from behind, ii. 909; Fergusson's recommendation to excise a considerable portion of the sciatic nerve in that operation, ii. 909; Syme's objections to amputation through the shaft of the thigh-bone, and recommendation to amputate through the condyles or trochanters, ii. 910; commented on by South, ii. 910; Liston's account of eighteen amputations through the thigh, ii. 910; report of twenty-eight amputations through the thigh, ii. 911; Syme and South on the formation of conical stumps, ii. 914; Syme on amputation through the epiphyses, ii. 915; *amputation through the leg*, ii. 915; directions for the operation, ii. 916; application of the tourniquet, ii. 916; South on the application of the tourniquet, ii. 916; modes of operating in amputation with the circular cut, ii. 916; amputation through the leg in its lower third, ii. 917; Salemi, Lenoir, and Baudens' modes of operating, ii. 917; disjointing the head of the fibula, ii. 917; Larrey's amputation through the head of the tibia, ii. 917; South on the seat of amputation through the leg, ii. 917; ligature of the vessels, ii. 918; after-dressing, ii. 918; South on the ligature of the retracted anterior tibial artery, in amputation high up through the leg, ii. 918; South on the treatment of hæmorrhage from the nutritious artery of the tibia, ii. 918; South on the bringing the edges of the wound together horizontally, ii. 918; South on the causes of subsequent sloughing of the integuments, ii. 918; amputation through the leg with a single flap, ii. 919; mode of operating, ii. 919; South's objections to flap operations on the leg, ii. 919; amputation through the leg with two flaps, ii. 919; mode of operating, ii. 920; Liston and Fergusson's mode of operating, ii. 920; amputation just above the ancle, ii. 921; Solingen, Dionis, White, Bromfield, Wright, Alanson, and Hey on this operation, ii. 921; Lawrence and South's cases, ii. 922; Liston's statistics of amputation through the leg, ii. 922; Lawrie's objection to amputation below the knee, ii. 922; South's tabular report of amputations through the leg, ii. 922; *amputation through the upper arm*, ii. 924; steps preliminary to the operation, ii. 924; Liston's statistics of the operation, ii. 925; South on the propriety of having a long stump if possible, ii. 925; South's tabular report of amputations through the upper arm, ii. 925; *amputation through the fore-arm*, ii. 926; directions for the operation, ii. 926; amputation with a single flap, ii. 926; with two flaps, ii. 926; South on flap amputations through the fore-arm, ii. 926; South's tabular report of amputations through the fore-arm, ii. 927; Liston's cases, ii. 927; amputation through the metatarsal and me-

tacarpal bones, ii. 927; application of the tourniquet, ii. 927; amputation through the metatarsal bone of the great toe, ii. 927; mode of operating when the flap is formed from the sole, ii. 927; when the flap is made from the inner side of the metatarsal bone, ii. 928; the bone best sawn through obliquely from within outwards, ii. 929; mode of operating when the flap is made from the dorsal surface of the metatarsal bone, ii. 929; South on the consequences of amputation through the metatarsal bone of the great toe, ii. 929; amputation through the intermediate metatarsal bones, ii. 929; mode of operating, ii. 929; amputation through the metacarpal bones, ii. 930; amputation through the metacarpal bone of the thumb, ii. 930; South and Liston on amputation through the metacarpal bones, ii. 930; amputation through the fingers and toes, ii. 930; amputation through the phalanges of the fingers, ii. 930; mode of operating, ii. 930; cutting off the finger with a chisel, ii. 931; Mayor on the amputation of the phalanges with the tachytome, ii. 931; *exarticulation or amputation through the joints*, ii. 931; cases in which exarticulation is required, ii. 931; Scoutetten's mode of operating, ii. 931; general directions, ii. 932: condition of the parts around the joint, ii. 932; *exarticulation of the thigh at the hip*, ii. 932; danger and statistics of the operation, ii. 932; Jaeger, Krimer, and South on the operation, ii. 933; cases requiring the operation, ii. 933; La Croix d'Orléans, Perrault, and H. Thomson's cases, ii. 933; the modes of operating, ii. 933; by the circular cut, ii. 934: Abernethy, Veitch, Cole, Jaeger, Kerr, and Graefe's modes of operating, ii. 934; by the flap-cut with a single flap, ii. 935; Puthod, Hunczorsky, Bryce, L'Alouette, Langenbeck, Delpech, Lenoir, Plantade, and Manec's modes of operating, ii. 935; with two flaps, ii. 937; Blandin, Larrey, Mott, Dupuytren, Lisfranc, von Walther, Vohler, Bell, Béclard, Liston, Begin, and Sanson's modes of operating, ii. 937; the oval cut, ii. 940; Sanson, Guthrie, Scoutetten, and Cornuau's modes of operating, ii. 940; the preference given to Larrey's operation, ii. 940; after dressing, ii. 942; *exarticulation of the leg at the knee*, ii. 942; opinions respecting the propriety of the operation, ii. 943; Jaeger's statistics of the operation, ii. 943; modes of operating, ii. 943; amputation with the flap-cut, ii. 943; Blandin, Rossi, Maingault, and Kern's operations, ii. 943; the circular cut, ii. 944; Velpeau, Cornuau, and Baudens' operations, ii. 944; the operation when the knee-cap is diseased, ii. 944; exarticulation at the ancle-joint an inferior operation to amputation through the leg, ii. 944; *exarticulation of the foot at the ancle*, ii. 944; Velpeau, Baudens, Syme, and Handyside's modes of operating, ii. 944; Syme on the advantages of this operation, ii. 946; *exarticulation of the tarsal bones*, ii. 946; the operation restricted to the removal of the astragalus and navicular bones, ii. 946; Hammond's case of exarticulation of the astragalus, ii. 946; Green's case, ii. 946; general directions for the operation, ii. 946; *amputation of the foot between the astragalus and navicular bones, and the heel and cuboid bones*, ii. 947; Chopart's operation, ii. 947; cases requiring the operation, ii. 947; mode of operating, ii. 947; when an under flap only is formed, ii. 947; when an under and upper flap are formed, ii. 948; Maingault's operation, ii. 948; Langenbeck, Klein, and Richerand's objections to the upper flap, ii. 948; Walther's operation preferred, ii. 948; Scoutetten's oval cut, ii. 949; Blasius' oblique cut, ii. 949; *exarticulation of the metatarsal bones*, ii. 949; advantages and disadvantages of the operation, ii. 949; Hey, Scoutetten, Lisfranc, and Münzenthaler's modes of operating, ii. 949; *exarticulation of single metatarsal bones*, ii. 951; preservation of the great toe important, ii. 952; mode of operating, ii. 952; *exarticulation of the metatarsal bone of the great toe*, ii. 952; mode of operating, ii. 952; Langenbeck and Scoutetten's operations, ii. 952; *exarticulation of the metatarsal bone of the little toe*, ii. 953; *of the middle metatarsal bones*, ii. 953; consentaneous removal of the diseased tarsal bones, ii. 953; Key, Dieffenbach, and Ruyer's cases, ii. 953; *exarticulation of the toes*, ii. 953; mode of operating with an under flap, ii. 953; with a flap on the dorsal surface, ii. 953; with an outer or inner flap, ii. 953; exarticulation of the second from the first phalanx, ii. 954; of all the toes at once, ii. 954; Scoutetten's operation, ii. 954; *exarticulation of the arm at the shoulder*, ii. 954; various modes of operating, ii. 955; compression of the subclavian artery by an assistant safer than with an instrument, ii. 955; Walther's operation by an upper and an under flap. ii. 955; dressing the wound, ii. 956; Le Dran, Garengeot, Dupuytren, Onsenoort, Lisfranc, and Champesme's modes of operating, ii. 956; the operation on the left arm, ii. 956; Astley Cooper's amputation at the shoulder-joint with a single flap, ii. 956; Hesselbach, Desault, Larrey, Langenbeck, and Dupuytren's modes of operating. ii. 957; exarticulation with the circular cut, ii. 958; Morand, Sharp, Nannoni, Bertrandi, Alanson, Graefe, Cornuau, Sanson, and B. Bell's operations, ii. 958; Scoutetten's operation with the oval cut, ii. 958; Dupuytren, Béclard, Bonfils, and Blasius' operations, ii. 959; circumstances which guide the choice of either of these methods, ii. 959; removal of the injured acromion or glenoid cavity, ii. 960; practised by Brown, ii. 960; recommended by Robinson and Fraser, ii. 960; Lisfranc's modification of the operation when performed prior to the age of fifteen, ii. 960; gun-shot wounds of the head of the humerus, ii. 960; excision of the head of the bone, or removal of the broken pieces requisite, ii. 960; Larrey's operation for the excision of the head of the humerus in such cases, ii. 960; Guthrie on gunshot wounds causing fracture of the humerus beneath and exterior to the capsular ligament, ii. 960; South on the excision of the acromion, glenoid cavity, or coracoid process in amputation at the shoulder-joint, ii. 961; Liston, South, and Astley Cooper's cases, ii. 961; *exarticulation of the fore arm at the elbow*, ii. 961; mode of operating according to Textor, ii. 961; Brasdor, Jaeger, Hager, Rodgers, Dupuytren, Velpeau, Cornuau, Textor, and Baudens' modes of operating, ii. 962; *exarticulation of the hand at the wrist*, ii. 963; modes of operating, ii. 963; Lisfranc's mode, ii. 963; South on the precautions to be taken in the flap-amputation at the wrist, ii. 963; *exarticulation of the metacarpal bones at their junction with the carpus*, ii. 963; mode of operating in exarticulating the metacarpal bone of the thumb, ii. 964; formation of the upper or under flap, ii. 964; exarticulation of the metacarpal bones of the ring and middle fingers, ii. 964; Langenbeck and Scoutetten's modes of operating, ii. 964; Scoutetten's oval cut in exarticulation of the middle metacarpal bone, ii. 964; mode of operating, ii. 964; in the exarticulation of both middle metacarpal bones, ii. 964; von Walther and Astley Cooper's modes of operating, ii. 965; Riadore, Guthrie, von Graefe, von Walther, Jaeger, Astley Cooper, Larrey, Tyrrell, and Bennaben's cases of excision of part of the hand, ii. 965; mode of operating in exarticulation of the four metacarpal bones, ii. 965; Troccon's mode of operating, ii. 965; when one metacarpal or metatarsal bone is diseased alone, it should be alone removed, ii. 965; excision of the first metacarpal bone, ii. 965; of the other metacarpal bones, ii. 965; of the first metatarsal bone, ii. 966; of the other metatarsal bones, ii. 966; *exarticulation of the fingers, at their junction with the metacarpal bones, and at their own joints*, ii. 966; Dupuytren and Lisfranc on exarticulation of the middle and ring fingers, ii. 966; Barthelemy on the section of the palmar aponeurosis after exarticulation of the fingers from the metacarpal bones, ii. 966; mode of operating in exarticulation of the joints of the fingers from each other, ii. 966; with two flaps, ii. 966; Lisfranc's flap operation, ii. 966; statistics of amputations, ii. 967; IMMEDIATE AMPUTATION, ii. 967; importance of the question, ii. 967; South on the comparative danger of primary and secondary amputation in severe injuries of the thigh, ii. 967; South's conclusion in favour of primary amputation, ii. 967; South on the minor danger in injuries of the leg or upper extremities, and the consequent propriety of immediate amputation, ii. 967; John Hunter's preference of secondary amputation, ii. 967; John Hunter's objections to primary amputation in severe injuries of the extremities, ii. 967; Astley Cooper's opinion in favour of immediate amputation in such cases, the constitution then having but one shock to sustain, ii. 967; Rutherford Alcock on the difference of the shock to the constitution in such cases, when occurring in civil life, and on the field of battle, ii. 967; *excision of the joints*, ii. 968; first performed on the knee-joint, ii. 968; afterwards extended to the other joints, ii. 968; Filkin, Vigaroux, David, White, Bent, Orred, Park, Moreau, Graefe, and Davie's cases, ii. 968; Sabatier, Percy, Roux, Moreau, Larrey, Guthrie, Syme, Textor, and Jaeger on the excision of joints, ii. 969; Wachter, Vermandois, Kohler, and Chaussier's experiments, ii. 969; objections to this operation as compared with amputation, ii. 969; advantages of the operation principally referable to the joints of the upper extremities, ii. 969; not so great in operations on the other joints, ii. 969; statistics of Jaeger, Syme, and Moreau's cases, ii. 970; Crampton on the excision of joints, ii. 970; cases in which excision of the ends of bones is preferable to amputation, ii. 970; contra-indications to the operation, ii. 971; mode of operating, ii. 971; direction and extent of the incision in the skin, ii. 971; excision of the diseased bone, ii. 971; extent of bone required to be removed, ii. 972; instruments for excising the ends of bones, ii. 972; arrest of the subsequent hæmorrhage, ii. 972; dressing the wound, ii. 972; after-treatment, ii. 972; untoward occurrences during the after-treatment, ii. 973; after-bleeding, ii. 973; abscesses, ii.

973; fistulous passages, ii. 973; necrosis of rare occurrence after this operation, ii. 973; after-treatment of the sawn ends of the bone, ii. 973; *excision at the shoulder-joint*, ii. 974; mode of operating in excision of the head of the humerus, ii. 974. C. White, Orred, Bent, Sabatier, Moreau, and Syme's modes of operating, ii. 974; motions of the arm subsequent to the operation, ii. 974; *excision of the elbow-joint*, ii. 975; Moreau's mode of operating, ii. 975; Dupuytren and Syme's modes of operating, ii. 975; Moreau on the division of the ulnar nerve in this operation, ii. 975; Dupuytren, Crampton, Jaeger, and Syme recommend its preservation, ii. 975; Jaeger's mode of operating, ii. 976; condition of the arm after excision of the elbow-joint, ii. 976; Crampton and Syme's cases, ii. 976; *excision of the wrist-joint*, ii. 976; Roux and Jaeger's modes of operating in excision of the lower ends of the radius and ulna, ii. 976; dressing the wound and after-treatment, ii. 977; Dubled and Velpeau's operations, ii. 977; Butt's case of excision of part of the necrosed ulna, ii. 977; *excision of the hip-joint*, ii. 977; mode of operating, ii. 977; by a simple longitudinal cut, ii. 977; by the formation of a flap, ii. 977; by Textor's oval cut, ii. 978; dressing the wound, ii. 978; White, Carmichael, Oppenheim, Hewson, Seutin, and Textor's cases, ii. 978; C. White on excision of the head of the femur, ii. 979; A. White and Fergusson's cases of excision of the head of the femur, ii. 979; *excision of the knee-joint*, ii. 981; Moreau, Park, Mülder, Sanson, Bégin, Jaeger, and Syme's modes of operating, ii. 981; Jaeger's operation preferred, ii. 981; Moreau, Park, and Jaeger on the mode of union after the operation, ii. 982; Syme on the treatment after the operation, ii. 982; A. White's case of compound dislocation of the femur behind the leg, ii. 982; *excision of the ancle-joint*, ii. 983; Moreau, Jaeger, Mülder, and Kerst's modes of operating, ii. 983; South on excision of the ancle-joint, ii. 984; dressing the wound, and after-treatment, ii. 985; *excision of the joints of the metacarpus and metatarsus*, ii. 985; mode of operating, ii. 985; after-treatment, ii. 985; Textor, Kramer, Roux, and Fricke's cases, ii. 985; *excision of the lower jaw*, ii. 986; cases requiring the operation, ii. 986; circumstances admitting a favourable result, ii. 986; priority of claim as originator of the operation, ii. 986; Tyrrell's case of necrosis of the lower jaw, ii. 986; *excision of the middle of the lower jaw*, ii. 987; mode of operating, ii. 987; retraction of the tongue, ii. 987; Dupuytren, Graefe, and Astley Cooper's cases, ii. 987; *removing a portion of the side of the lower jaw without the condyle*, ii. 988; mode of operating, ii. 988; Deadrick, Mott and Wardrop's cases, ii. 988; *excision of the lower jaw with its condyles*, ii. 989; Mott, Schindler, von Graefe, Syme, Jaeger, and Cusack's modes of operating, ii. 989; Mott, von Graefe, Dzondi, Jaeger, and Schindler on the previous ligature of the carotid artery, ii. 990; White's case of excision of the lower jaw, ii. 991; Graefe and Mott's cases of exarticulation of one side of the lower jaw, ii. 992; Cusack on the non-necessity of tying the carotid artery prior to the operation, ii. 993; Cusack's cases of exarticulation of the lower jaw, ii. 993; Liston's mode of operating, ii. 993; Perry's case of necrosis of the lower jaw, ii. 994; *resection of the upper jaw*, ii. 994; cases in which the operation is indicated, ii. 994; Dupuytren's cases of extirpation of the upper jaw doubted by Gensoul, ii. 994; Akoluthus' case, ii. 994; Dr. T. White's case of almost complete extirpation of the upper jaw, ii. 994; mode of operating, ii. 995; section of the skin and muscles, according to Gensoul and Dieffenbach, ii. 995; Lizars the first to recommend the entire removal of the upper jaw, ii. 996; his description of the proposed operation, ii. 996; Lizars' cases in which he attempted to perform the operation, but failed on account of the hæmorrhage, ii. 996; Lizars' cases in which he performed the operation, ii. 996; Gensoul's case of extirpation of the superior maxillary bone, ii. 997; cutting away the diseased jaw, ii. 997; Heyfelder's operation for the resection of both jaws, ii. 998; Syme, Liston, and Fergusson's modes of operating, ii. 998; O'Shaugnessy's case of removal of the upper jaw, ii. 999; Hetling's case of osteosarcoma of the jaws, in which he removed part of the upper, and part of the lower jaw, ii. 1000; Liston on the prospect of ultimate success in this operation in cases of malignant disease, ii. 1001; dressing the wound, and after-treatment, ii. 1001; dangerous symptoms which may occur after the operation, ii. 1001; recurrence of the disease, ii. 1001; *resection of the scapula* (blade-bone), ii. 1002; von Walther's mode of operating, ii. 1002; Haymann's operation, ii. 1002; Liston, Janson, Luke, Syme, and Travers' cases, in which resection of the scapula was performed, ii. 1002; James' case of tearing away the arm and scapula by machinery, ii. 1003; *resection of clavicle* (collar-bone), ii. 1003; cases requiring the operation, ii. 1003; mode of operating, ii. 1003; Cuming, Meyer, Roux, Warren, Mott, Travers, and Chaumet's cases in which resection of the clavicle was performed, ii. 1003 ; *resection of the scapula and clavicle* together, ii. 1004 ; Mussey, M'Clellan, Gilbert, and Fergusson's cases ii. 1004 ; Fergusson's mode of operating, ii. 1005 ; Gaetani Bey's case of resection of the scapula, and of the acromial end of the clavicle, ii. 1005 ; *resection of the ribs*, ii. 1005 ; mode of operating, ii. 1006 in compound comminuted fracture, ii. 1006 ; Textor and Warren's cases of resection of a rib, ii. 1006 ; Dixon's resection of the cartilage of a rib, ii. 1006 ; Roux' case of resection of rib on account of necrosis, ii. 1006 ; *resection of the fibula*, ii. 1007 ; Seutin and Malgaigne's cases, ii. 1007 ; resection of other bones, ii. 1007.

SUTCLIFFE'S performance of the Taliacotian operation, ii. 831.

SUTTON'S, Dr. case of a foreign body remaining a long while in the windpipe, ii. 396 ; case of ovarian dropsy, with discharge of hair by the wound made in tapping, ii. 492.

SWAN'S case of fracture of the neck of the femur within the capsule united by bone, i. 567 ; case of division of the peroneal nerve, ii. 887.

SWEDIAUR proposes the word blenorrhagia in lieu of gonorrhea, i. 155 ; objections to the use of corrosive sublimate in cases of syphilis in infants, i. 674.

Synovial membrane, inflammation of. *See* Inflammation of the Joints.

SYME on inversion of the foot in fracture of the neck of the femur, i. 565 ; distinguishing character of caries, i. 682; characters of caries, i. 684 ; treatment of caries, i. 686 ; case of destruction of the bones of the face, i. 699 ; salivary calculi, i. 715 ; prolapsus ani, ii. 130 ; characters of prolapsus ani, ii. 131 ; diagnosis between prolapsed rectum, and hæmorrhoids and intus-susception, ii. 131 ; case of wry-neck, ii. 153 ; distorted position of the head caused by caries between the occiput and atlas liable to be mistaken for wry-neck from muscular contraction, ii. 153 ; wry-neck a cause of lateral curvature, ii. 161 ; section of muscles in spinal curvature, ii. 169 ; carotid aneurism, ii. 232 ; removal of internal piles by ligature, ii. 302 ; seat of stricture in the rectum, ii. 336 ; case of subcutaneous section for foreign bodies in joints, ii. 710 ; prefers Liston's flap-operation for the thigh, ii. 909 ; objects to amputation through the shaft of the femur, and recommends amputation through the condyles, or trochanters, ii. 910 ; formation of conical stumps in flap-amputations of the thigh ; ii. 914 ; amputation through the epiphyses of the femur, ii. 915 ; mode of amputating at the ankle-joint, ii. 945 ; advantages of this operation, ii. 946 ; excision of joints, ii. 969 ; statistics of cases, ii. 970 ; mode of operating in excision of the head of the humerus, ii. 974 ; in excision of the elbow-joint, ii. 975 ; recommends the non-division of the ulnar nerve in that operation, ii. 975 ; cases of excision of the elbow-joint, ii. 976 ; mode of operating in excision of the knee-joint, ii, 981 ; treatment after the operation, ii. 982 ; mode of operating in excision of the lower jaw with the condyles, ii. 989 ; in resection of the upper jaw, ii. 998 ; case of resection of the scapula, ii. 1003.

SYMOND'S, Dr. case of removal of the inverted womb by ligature, ii. 121.

Symphysiotomy, ii. 445.

SYPHILIS ;—question of its identity with gonorrhea, i. 162 ; observations and experiments of Hernandez and Ricord, i. 162 ; Hunter on the identity of the two poisons, i. 163 ; accounts for the different effects of the same poison by the gonorrhea proceeding from a secreting surface, and the chancre being formed on a non-secreting surface, i. 163 ; South on the frequency of the co-occurrence of chancre and gonorrhea, i. 164 ; Benjamin Bell denies the identity of gonorrhea and syphilis, i. 164 ; Hernandez' experiments on the subject, i. 164 ; ulcers produced by inoculating with gonorrheal virus not syphilitic, i. 165 ; Ricord's observations and experiments, i. 165 ; Ricord's inferences from the results of the inoculalation with gonorrheal matter, i. 165 ; *venereal ulcers*, i. 640 ; distinguished as primary and secondary, i. 641 ; causes, i. 641 ; South on the inappropriate use of the terms "venereal ulcer" and "chancre" as synonymous, i. 641 ; John Hunter on the two modes in which the venereal poison affects the system, i. 641 ; Lawrence on the progress of syphilis from one part of the body to another, i. 642 ; the operation of the venereal contagion requires a peculiar delicate structure of the part affected, or a deprivation of its cuticle, i. 642 ; symptoms of chancre, i. 642 ; characters of the pus secreted by venereal ulcers, i. 642 ; John Hunter and Ricord on the period at which chancres appear after infection, i. 642 ; John Hunter on the symptoms of chancre, i. 642 ; Lawrence on the progress of ulceration in a syphilitic sore, i. 643 ; Lawrence on the five kinds of syphilitic sores, i. 643 ; the pus of the ulcer the special vehiole of the venereal contagion, i. 644 ; Hunter's experiments by inoculating with the matter of gonorrhea and chancre, i. 644 ; Ricord on inoculation for the purpose of distin-

guishing syphilitic sores, whether primary or secondary, i. 644; buboes the first symptoms of general syphilis, i. 645; may be idiopathic, or sympathetic, i. 645; symptoms, progress, and terminations, i. 645; John Hunter on the true venereal buboes, i. 645; Ricord on the seven kinds of buboes, i. 645; Hunter and Ricord on the existence of syphilitic buboes, without primary sore, i. 646, 647; general syphilis attacks specially either the skin, mucous membranes, or bones, i. 647; John Hunter on the continuance of the constitutional irritation from lues, independent of continued absorption i. 647; inflammation of the mucous membrane of the throat, i. 647; symptoms, appearances, and results, i. i. 647; venereal eruptions, i. 648; symptoms, i. 648; Lawrence on the four kinds of syphilitic eruptions, i. 648; herpetic eruptions, rhagades, verrucæ, and condylomata, i. 649; John Hunter and Ricord on the non-infectious character of the pus from a secondary syphilitic sore, 649; symptoms and results of syphilis in the bones, i. 650; modifications of the symptoms of syphilis, i. 650; primary syphilitic ulcers no decided external character, i. 651; Abernethy on pseudo-syphilis, i. 651; Abernethy on the means of distinguishing between true and false syphilis, i. 651; Carmichael's objections to the terms syphilis, syphiloidal, and pseudo-syphilis, i. 652; Carmichael bases his arrangement of venereal complaints on the character of the eruption, i. 652; Ricord on the causes of the varied appearances of chancre or primary syphilitic sore, i. 653; differences in secondary syphilis, i. 654; prognosis, i. 654; John Hunter on the relative rapidity of cure of gonorrhea, chancre, and lues venerea, i. 654; Abernethy on the occasional spontaneous healing of chancre, i. 655; John Hunter on the relapse of ulcers after chancres have cicatrized, i. 655; *treatment of syphilis with mercury*, i. 655; in treating chancre, an especial indication to prevent general syphilis, i. 655; local treatment, i. 655; Ricord on the destruction of the ulcer by the nitrate of silver i. 655; internal exhibition of mercury, i. 655; Lawrence on the exhibition of mercury in cases of chancre, and on the rarity of the occurrence of secondary symptoms when mercury has been used, i. 656; Lawrence on the extent to which the use of mercury may be pushed, i. 656; Green on the use of mercury in syphilis, and on the forms in which it should be employed, i. 656; circumstances requiring the local exhibition of corrosive sublimate, i. 658; Delpech on frictions with the ung. hyd. cin. in primary syphilis, i. 658; South on the treatment of sloughing chancre, i. 658; mercury not to be used either internally or externally under such circumstances, i. 658; mercury should be exhibited for some time in smaller doses after the chancre has cicatrized, i. 659; treatment of buboes, i. 659; tendency of idiopathic buboes to suppurate, i. 659; treatment of the remaining ulcer, i. 659; treatment of the indurated bubo i. 659; mode of opening suppurating buboes, i. 659; Ferguson, Fricke, Reynaud, and Ricord on the treatment of buboes, i. 659; South on the treatment of suppurating bubo, and of the subsequent ulcer, i. 659; treatment of general syphilis by mercury, i. 660; external employment of mercury, when required, i. 660; sublimate baths, i. 660; the internal exhibition of mercury preferable in ordinary syphilis, i. 660; local symptoms require special treatment, i. 660; Rust's treatment of syphilitic ulceration of the throat and palate, i. 660; treatment of syphilitic eruptions, i. 660; treatment of the granulations by caustic or the knife, i. 661; of syphilitic diseases of the bones, i. 661; mercurial fumigation in syphilitic ulceration of the tonsils and pharynx, i. 661; South on secondary syphilitic sores and their treatment, i. 661; South on the treatment of nodes, i. 662; necessary to vary the mercurial preparations in use according to constitution and other circumstances, i. 662; Starke on the phosphor. hydrarg. von Graefe on the iodide and bromide of mercury, and Mendaga and Parent on the hydrarg. cyan., i. 662; salivation not necessary for the cure of the venereal disease, i. 662; treatment of salivation, i. 663; treatment of old cases of venereal disease, i. 663; Louvrier and Rust on the friction-cure, i. 663; cases in which the friction-cure is indicated, i. 663; cases in which it is contra-indicated, i. 663; South on the friction-cure, i. 664; mode of employing it, i. 664; Wedemeyer, Rust, and South on the number of times the frictions may require to be practised, i. 664; the order in which the rubbings-in are to be conducted, i. 665; symptoms which occur during this treatment, i. 665; the Montpellier modification of the friction-cure condemned, i. 666; treatment to be adopted, if the salivation or critical sweating be suddenly suspended, i. 666; occurrence of spasmodic or nervous symptoms, i. 666; subsequent treatment, i. 666; Weinhold's mercurial cure, i. 666; mode of employing it, i. 666; Zittmann's decoction, i. 667; mode of exhibiting it, i. 667; formula for Zitt-

mann's decoction, i. 667; the Arabian treatment, i. 668; Dzondi's treatment, i. 668; the preference given to the use of Zittmann's decoction, i. 668; *treatment of syphilis without mercury*, i. 669; various modes of treating secondary symptoms without mercury, i. 669; Pitcairn, Chréstien, and Niel on gold and its preparations in primary and secondary syphilis, i. 669; Ricord, Eusèbe de Salle, Lallemand, Biett, Pailland, Wallace, Dr. Williams, Judd, Tyrrell, Ebers, von Hasselberg, and Hacker on iodine and hydriodate of potash in gonorrhea and general syphilis, i. 669; Forster on the cure of syphilis by the chloride of gold and soda, i. 670; treatment of syphilis without mercury in England, i. 670; Hill, Hennen, Rose, Guthrie, and Thomson on the duration of the disease under this treatment, and on the subsequent occurrence of secondary symptoms, i. 671; South on the proper mode of exhibiting mercury in the treatment of syphilis, i. 671; objections to the treatment without and with mercury i. 671; *syphilis in infants*, i. 673; causes of infection, i. 673; Evanson and Maunsell on the communication of syphilis to the fœtus in the womb, i. 673; Huguier on the period at which syphilis shews itself after birth, i. 673; infection of the child by a syphilitic nurse, i. 673; Dyckman's assertion that the child may be infected by the milk of a diseased nurse, i. 673; Hunter, Lawrence, and Todd's cases of diseased children infecting the nurses, i. 673; Colles doubts whether the child can infect the nurse, unless she have ulceration of the nipple, i. 673; Evanson and Maunsell on the symptoms of syphilis in infants, i. 673; Lawrence on syphilitic iritis, and ulceration about the anus in infants, i. 674; prognosis, i. 674; Evanson and Maunsell on the treatment of syphilis in infants, i. 674; Swediaur and Bacot object to the use of corrosive sublimate in such cases, i. 674; Hey, Lawrence, Hunter, Ricord, and South on the possibility of infection from secondary syphilis, i. 675.

Tait's case of ligature of both the external iliacs, ii. 259.

Taliacotian operation, ii. 831.

Tanchou's caustic-holder for stricture of the urethra, ii. 370.

Taramelli's case of hernia of the vermiform appendix, ii. 3.

Tarsal bones, exarticulation of, ii. 946.

Tarsus, fracture of, i. 584; dislocation of the bones of, i. 809.

Tavignot on the use of oil varnish on starch bandages in fractures in young children, i. 505; subcutaneous ligature of the superficial arteries, ii. 228; treatment of spina bifida by closure of the sac, ii. 469.

Taylor on the rarity of carbonate of lime calculi, ii. 518; on calculi of children, ii. 523; hour-glass calculi, ii. 546.

Teeth, caries of, i. 700; extraction of, i. 704; replacement of, ii. 849; supernumerary, ii. 850.

Telangiectasy, ii. 280; congenital, ii. 280; characters, ii. 280; fungous growths after rupture of the swelling, ii. 280; nature of the disease, ii. 280; complications, ii. 281; *telangiectasis lipomatodes*, ii. 281; causes, ii. 281; always a local disease, ii. 281; prognosis, ii. 281; treatment, ii. 281; by compression, ii. 282; Abernethy on compression, ii. 282; by extirpation with the knife, ii. 282; with the ligature, ii. 282; advantages of the ligature, ii. 282; Lawrence, Brodie, and South on the application of the ligature, ii. 282; destruction of teleangiecta[illegible] by caustic, ii. 283; South on caustic in teleangiectasy, ii. 284; various remedies to induce inflammation and suppuration in the diseased growth, ii. 284; Pattison, Smith, and Tyrrell's cases, ii. 285; tying the principal trunk supplying the diseased growth, ii. 285; if the teleangiectasy be seated on the extremities, and incurable, amputation must be performed, ii. 286; Pauli on the tattooing of moles on the skin, ii. 286.

Temporal artery, ligature of, ii. 239.

Tessier proves that animals are subject to gangrene from the use of spurred rye, i. 61.

Testicle, inflammation of, orchitis, hernia humoralis:—Benjamin Bell on alternate swelling of the testicles, i. 177; causes—gonorrhea as a cause, i. 177; epididymitis, i. 177; Hunter on the period when swelled testicle supervenes, i. 177; may be a symptom of general syphilis, i. 177; Hunter says swelling of the testicles is from sympathy, and not from syphilis, i. 177; Astley Cooper and Ricord describe syphilitic swelling of the testicle, i. 178; external injury, cold, and violent exertions may induce orchitis, i. 178; Hunter on gout as a cause, i. 178; Astley Cooper mentions enlargement of the prostate in old age, inflammation of the neck of the bladder, a stone passing through the ureter, or pressing on the commencement of the urethra, as causes of swelled testicle, i. 178; South on congestion of semen in the seminal tubes as a cause of orchitis, i. 178; symptoms and terminations of orchitis, i. 178; suppuration to be feared when the pain is throbbing, i. 179; induration not an uncommon termination, i. 179; gangrene rare,

i. 179; Astley Cooper on the symptoms and progress of orchitis, i. 179; occasionally preceded by great irritation of the brain, i. 179; Sams' case of cerebral irritation preceding an attack of orchitis, consequent on gonorrhea, i. 179; subsidence of orchitis generally followed by a return of gonorrhea, i. 179; Astley Cooper on adhesion and thickening of the tunica vaginalis, i. 179; suppuration rare when the inflammation is sympathetic, i. 180; Astley Cooper on suppuration of the testicle, i. 180; bursting of the abscess sometimes followed by a fungous growth, i. 180; symptoms and progress of orchitis serve to distinguish it from any other disease, i. 180; S. Cooper's case of orchitis, simulating strangulated rupture, i. 180; swelling of the testicle from blows takes place very rapidly, i. 180; Astley Cooper and South on wasting of the testicle, caused by inflammation, i. 180; Astley Cooper on the more frequent seat of the disease in the globus major, i. 180; treatment of orchitis, i. 180; South on the treatment, i. 181; treatment of suppuration and abscess of the testicle, i. 181; South on the treatment of fungus of the testicle, consecutive to abscess, i. 181; treatment of induration, i. 181; occasional termination of induration in sarcoma and scirrhus, i. 181; treatment of orchitis from cold or external injury, i. 182; Fricke on compression in orchitis, i. 182; South on the treatment by compression, i. 182; mode of application of compression, i. 182; South on the application of compression, i. 183; subsequent treatment, i. 183; South on the results of compression, i. 183; South's case of metastasis of gonorrhea and inflammation of the testicle to the brain, i. 183; great care required in the application of the plasters for compression, i. 184; the advantages of compression, according to Fricke, i. 184; *wounds of, and of the spermatic cord*, i. 488; treatment of the accompanying inflammation, i. 488; if the testicle be destroyed, either by the injury or the subsequent suppuration, it must be removed, i. 488; wounds of the cord, involving the nerves and vessels of the testicle, cause its shrivelling or decay, i. 488; South's case of tapping a hydrocele, with supposed wound of the testicle, i. 489.

Testicle, cancer of, ii. 803; sarcocele, ii. 804; cystic swelling of, ii. 809; hydatids of, ii. 809; fungus of, ii. 810; scrofulous swellings of, ii. 810; syphilitic swellings of, ii. 810; medullary fungus of, ii. 810; extirpation of, ii. 812; undescended testicle, and its treatment, ii. 813.

Tetanus, i. 376; varieties, i. 377; Travers on traumatic tetanus, i. 377; Travers on the period of accession of the disease after the receipt of the injury, i. 377; Dr. Robison's case, i. 377; Brodie, Sir James M'Grigor, and Blane on the period of accession of tetanus after the receipt of the injury, i. 377; three stages of tetanus, i. 377; symptoms, i. 377; Lawrence and Abernethy on a costive state of the system preceding tetanus, i. 378; Hunter on the cause of death in, i. 378; state of the intellect in, i. 378; Samuel Cooper's case of chronic tetanus of five weeks' duration, i. 378; proximate cause, i. 378; Froriep, Friedrich, Curling, South, and Lawrence on the proximate cause, i. 378; remote causes, i. 379; John Hunter, Travers, and Samuel Cooper on the causes, i. 379; Dr. Bardsley on the diagnosis of tetanus from hydrophobia, i. 380; prognosis always extremely unfavourable, i. 380; Dr. O'Beirne and Hennen on its fatal character, i. 380; South on the favourable termination of cases which pass over the seventh day, i. 380; treatment, i. 380; Larrey and Dupuytren on amputation in, i. 380; general treatment, i. 380, 381; Klein and Treswart on the use of prussic acid in, i. 381; Smith on colchicum in, i. 381; South on long and free incisions on either side of the spine, and cauterizing the wounds, i. 381; exhibition of opium in, i. 381; South on the treatment of, i. 382.

Textor on dislocation of the head of the thigh-bone downwards and inwards in hip-disease, i. 258; case of reduction of the consecutive dislocation, i. 268; on the arrest of hæmorrhage by nature, i. 297; effects of torsion, i. 311; dressing the wound after the operation for rectal fistula, i. 731; ligature of the femoral below Poupart's ligament, ii. 262; cutting away the tunica vaginalis, ii. 506; mode of amputating the thigh with a flap from the outer side, ii. 909; from the inner side, ii. 909; mode of operating in exarticulation of the fore-arm at the elbow, ii. 961, 962; excision of joints, ii. 969; case of excision of the head of the femur, ii. 978; of excision of the head of a metacarpal bone, and of the os magnum, ii. 985; of resection of a rib, ii. 1006.

Theden's apparatus for fracture of the neck of the femur, i. 569; ligature of the hernial sac for its radical cure, ii. 24.

Thevenin on dilatation of the stricture in strangulated hernia without cutting, ii. 38.

Thierry on torsion of arteries, i. 308, ii. 227; mode of practising torsion, i. 309.

Thigh, artificial, ii. 847; amputating through, ii. 906; exarticulation of at the hip-joint, ii. 932.

Thilenius' case of reduction of the con-

secutive dislocation in hip disease, i. 268; division of the tendo Achillis in club-foot, ii. 186.
THOMSON'S, Dr., observations on the variation of the current of the blood through the capillaries, resulting from the application of different substances, i. 27; mortification from the use of spurred rye, i. 61; objections to John Hunter's views on "quick union," i. 288; splitting of the ball in gun-shot wounds by the sharp edge of a bone, i. 339; sabre-wounds of the head, i. 388; sabre-cuts of the head and neck, and the infrequency of hernia cerebri, i. 389; amaurosis and inflammation of the eye caused by the passage of a ball through or near the organ, i. 428; duration of syphilis under the non-mercurial treatment, and subsequent occurrence of secondary symptoms, i. 671.
THOMSON, H., on the protraction of the period of incubation in hydrophobia, i. 366; case of amputation at the hip-joint, ii. 933.
Throat, polypus of, ii. 738.
Thumb, exarticulation of the metacarpal bone of, ii. 964.
THUNE on the causes of splay-foot, ii. 186; primitive and secondary valgus, ii. 186.
Thyroid rupture, ii. 87.
—— gland, inflammation of, ii. 652.
—— artery, superior, ligature of, ii. 656.
    inferior, ligature of, ii. 659.
Tibia, fracture of, i. 581.
Tibial artery, anterior, aneurism of, ii. 265; ligature of, ii. 266; posterior, aneurism of, ii. 265; ligature of, ii. 266.
TIEDEMANN on the high bifurcation of the brachial artery, ii. 252.
Tinea capitis and its varieties, i. 631.
TITLEY'S, Dr. case of sarcomatous tumor of the scrotum, ii. 711.
TODD, Dr. considers there is a difference between temporary and articular cartilage, i. 224.
TODD'S case of a syphilitic child infecting its grandmother, i. 673.
Toes, union of, ii. 308; supernumerary, ii. 850; amputation of, ii. 930; exarticulation of, ii. 953.
Tongue, unnatural adherence of, ii. 314; enlargement of, ii. 649; cancer of, ii. 776; removal of by ligature, ii. 778; extirpation of, ii. 779.
Tooth-ache, i. 700.
TONSILS, INFLAMMATION OF—QUINSY:—symptoms, i. 139; causes and terminations, i. 140; abscess, i. 140; Dr. Tweedie on enlargement of, i. 140; Guersent's cases of gangrene of, i. 140; treatment, i. 140; Dr. Watson on the local treatment, i. 140; Hercy's inhaler, i. 141; scarifications, i. 141; danger of wounding the carotid, or a branch, i. 141; Watson's cases, i. 141; South's recommendation of the actual cautery in case an arterial branch were wounded, i. 141; astringent gargles to be used on the subsidence of the inflammation, i. 141; opening the abscess with a guarded bistoury or the pharyngotome, i. 141; treatment after the pus has been evacuated, i. 141; in rare cases the abscess becomes external under the jaw, i. 141; Allan Burns on the spontaneous bursting of the abscess, i. 141; attended with much danger, i. 142; details of a case in which the trachea was deluged with purulent matter, and death by suffocation ensued, i. 142; Burns' advice in such cases to tap the abscess with trocar and canula, i. 142; in most cases of tonsillar abscess the action of emetics will cause its rupture; if not, it must be opened, i. 142; Burns' directions for opening a tonsillar abscess, i. 142; South's, i. 142; cases of fatal hæmorrhage consecutive to opening a tonsillar abscess, mentioned by Portal, Allan Burns, Tyrrell, and Brodie, i. 142; Lawrence's case of alarming hæmorrhage from puncturing an immature tonsillar abscess, i. 142; hardening of the tonsils, i. 143; Else denies the existence of the so-called scirrhus of the throat, i. 143; Dr. Tweedie ascribes such cases to hypertrophy and induration alone, i. 143; roughness of the voice and deafness caused by enlarged tonsils, i. 143; South on the treatment of enlarged tonsils, i. 143; Allan Burns on the formation of calculi in the tonsils, i. 143; partial extirpation of enlarged tonsils, i. 144; description of the operation, i. 144; ligature of the tonsils, or the application of caustic not to be preferred to their removal by the knife, i. 145; various modes of effecting their removal by cutting, tearing out, tying, or by destroying with caustic, i. 145; the operation by cutting performed by Celsus, Richter, and Moscati, i. 145; that of tearing out the tonsils by Celsus and Fabricius ab Aquapendente, i. 145; tying the tonsils by Guillemeau, Sharp, Cheselden, Bibrach, Siebold, Bell, Chevalier, and Hard, i. 145; cauterizing the tonsils with red-hot iron or caustic by Severinus and Wieseman, i. 145; Else's objection to excision, especially in children, on account of the hæmorrhage, i. 145; prefers Cheselden's operation, i. 145; Physick's guillotine instrument for amputating the tonsils, i. 145; Simpson's adaptation of Thorbern's staphylotome for the same operation, i. 145; the operation performed in the United States with scissors in preference to the knife, i. 146; Gibson's forceps, i. 146; South on this operation, i. 146; means of stopping the hæmor-

rhage, i. 146; Lawrence and Callaway on the hæmorrhage following extirpation, i. 146; Shaw's case of extirpation followed by superficial slough, alarming hæmorrhage, and ligature of the carotid, i. 146; *relaxation of the uvula*, i. 147; extirpation of the uvula, i. 147; Bennati recommends cauterization with nitrate of silver, i. 147; Paulus Ægineta cauterizing it with the aid of the staphylokauston, i. 147; Paré used the ligature, i. 147; Astley Cooper and South's opinions against the operation, i. 147.

Torsion of arteries, i. 308.

Tournel's case of dislocation of the scapular end of the clavicle downwards, i. 780.

Toynbee on the synovial membrane, i. 212; non-vascularity of cartilage, i. 225, 227; development of, i. 225; supply of nutrient fluid to articular cartilages, i. 225; vessels by which articular cartilages are nourished, i. 226; description of the canals in adult cartilage, i. 226; removal of the articular cartilages in old age, i. 241.

Trachea, foreign bodies in, ii. 394.

Tracheotomy, ii. 401.

Transfusion, ii. 878.

Travers on the cause of pain in inflammation, i. 25; remarks that pain is not necessarily an attendant on inflammation, i. 26; redness in inflammation, i. 26; increase of heat in inflammation, i. 27; experiments of Dr. John Thomson repeated by, i. 29; oscillation attending the recovery of the circulation in inflammation, i. 29; effusion of serum, i. 33; lining membrane of an abscess, i. 38; the circumstances which determine an abscess to the surface, i. 38; purpose which the formation of pus serves in the economy, i. 39; constitution of pus, i. 42; process of ulceration, i. 52; objection to the terms mortification and sphacelus, i. 53; acute gangrene, i. 54; deep and extensive effusions and injuries of nerves causes of mortification, i. 55; chronic gangrene, i. 58; severe phlebitis, i. 78; primary symptoms of gonorrhea, i. 156; gonorrheal sores, and their consequences, i. 166; secondary symptoms of gonorrheal sores, i. 166; paronychia affecting the tendons, i. 193; the blood as a medium of organized adhesion in wounds, i. 289; formation of new vessels, i. 292; filling up a gaping wound, i. 293; case of wound of the posterior tibial artery, i. 305; traumatic tetanus, i. 377; period of the accession of the disease after the receipt of the injury, i. 377; causes of tetanus, i. 379; case of suicidal wound of the lingual or facial artery near its origin, with unsuccessful ligature of the common carotid, i. 432; effects of injury of the abdomen, i. 457; wounds of the abdomen, i. 458; case of wounded intestine, i. 462; wounds of the intestines communicating directly with the surface, i. 463; varieties of wounds of the intestines, i. 463; experiments on wounded intestine, i. 465, 467; objections to returning a wounded intestine without suture into the abdomen, i. 468; withdrawal of the suture after union has taken place, i. 468; directions for stitching a wounded intestine, i. 468; reparation by artificial connexion of the divided parts of a wounded intestine, i. 470; treatment of wounded intestine, without feculent discharge or prolapse, i. 471; spontaneous reparation in wounded intestine, i. 471; effusion into the cavity of the abdomen in cases of penetrating wounds, i. 472; impediments to effusion of the intestinal contents in wounds of the bowels, i. 472; case in which he applied a ligature round the wound of a protruded stomach, i. 476; combined effects of mercury and syphilis in the production of the mercurial disease, i. 677; cachexia mercurialis, i. 678; nature of strangulation in ruptures, ii. 11; effects produced by the ligature on the arterial coats, ii. 219; case of ligature of the carotid, ii. 233; treatment of branching aneurism, ii. 275; case of suppuration of the bursa of the knee-cap, ii. 461; treatment of hydrocele by punctures, ii. 500; case of impaction of calculus in the ureter, ii. 544; of secondary hæmorrhage after lithotomy, ii. 604; of calculus in the urethra, ii. 630; of stone broken up under the use of a constitutional stone-solvent, ii. 634; on the genus carcinoma, ii. 716; occasional inertness of scirrhus during life, ii. 768; resemblance of chimney-sweep's cancer to lupus, ii. 816; case of resection of the scapula, ii. 1003; of resection of the clavicle, ii. 1004.

Travers', jun. case of dislocation into the ischiatic notch in a boy five years old, i. 764; case of a foreign body in the windpipe for a long time, ii. 396.

Trepanning, } the operations of, i. 419. *See*
Trephining, } Wounds of the Head.

Treswart on the exhibition of prussic acid in tetanus, i. 381.

Troccon's mode of operating in exarticulation of the four metacarpal bones, ii. 965.

Troja on incipient production of new bone after necrosis, i. 693.

Trolliet considers the mucus from the inflamed mucous membrane of the bronchi in hydrophobia to be the vehicle of the poison, i. 364.

Trousseau on tracheotomy in croup, ii. 399.

Tubercle in bone, ii. 681.

Tumours, adipose, ii. 690; encysted, ii. 694; atheromatous, ii. 696; sebaceous, ii. 697; sarcomatous, ii. 710; lardaceous, ii. 712.

Tunaley's case of a bristle in the œsophagus, ii. 384.

Turchetti's cases of malignant pustule, described by him as anthrax, i. 66.

Tweedie, Dr. on enlargement of the tonsils, i. 140; ascribes cases of the so-called scirrhus of the tonsils to hypertrophy and induration alone, i. 143.

Tympanitis, ii. 495.

Tyrrell's case of fatal hæmorrhage consecutive to opening a tonsillar abscess, i. 142; of protracted gleet, i. 173; distinction between gonorrheal gleet, and gleet from stricture, i. 173; diagnosis between inflammation and hysterical affections of the joints, i. 249; adhesive plaster, i. 325; case of wounded intestine, i. 462; of trepanning the spine, i. 538; hydriodate of potash in general syphilis, i. 669; case of compound dislocation of the sternal end of the clavicle backwards, i. 778; of hook-foot, arising from an accident, ii. 190; of the existence of several aneurisms in the same person, ii. 204; of teleangiectasy treated by injecting a solution of alum, ii. 285; of a broken piece of catheter in the bladder, ii. 417; section of the prostate in the operation for stone, ii. 590; case of inhealing of a metallic frame to remedy a sunken nose, ii. 845; of excision of part of the hand, ii. 965; of necrosis of the lower jaw, ii. 986.

Ulceration:—causes, i. 49: Hunter on ulcerative inflammation, i. 49; ulcerative absorption, or absorption with suppuration, i. 50, 51; progressive absorption, i. 51; Travers on the process of ulceration, i. 52; ulceration of the synovial membrane, i. 214.

Ulcers in general:—definition of, i. 613; causes, internal and external, i. 613; division of ulcers into simple and complicated, i. 613; subdivisions of complicated ulcers, i. 613; reaction of ulcers on the organism, i. 613; prognosis, i. 614; treatment, i. 614; three stages of the progress of ulcers towards healing, i. 614; symptoms and treatment of an inflamed ulcer, i. 614; of the erethetic ulcer, i. 615; of the torpid ulcer, i. 615; symptoms, appearances, and treatment of the foul or gangrenous ulcer, i. 615; Percy, Labarraque, Lisfranc, Lemaire, Ekl, Klimatis, Biett, Cloquet, Cullerier, Boulay, and Pigné on the solution of the chloride of lime in foul, gangrenous, and torpid ulcers, i. 615, 616; symptoms and treatment of the callous ulcer, i. 616; of the œdematous ulcer, i. 616; of the fungous ulcer, i. 616; of varicose ulcer, i. 617; issues required if the ulcers are of long standing, i. 617; *atonic ulcers*, i. 618: causes, situation, and symptoms, i. 618; prognosis, i. 618; treatment, i. 618; application of sticking-plaster, i. 619; Underwood and Boyer allow the patient to walk while wearing the sticking-plaster, i. 619; local application of aromatic and astringent remedies, i. 619; Rust's treatment of chronic ulcers of the foot by the hunger-cure, i. 619; South on the applications of strips of plaster in the treatment of ulcers, i. 619; general treatment, i. 620; prevention of relapses, i. 620; *scorbutic ulcers*, i. 620; causes and symptoms, i. 620; characters, i. 621; occasional causes of scurvy, i. 621; Bateman on purpura hæmorrhagica, or land scurvy, i. 621; general and local treatment, i. 621; *scrofulous ulcers*, i. 622; causes, i. 622; indications of the scrofulous disposition, i. 622; diseases dependant on scrofula, i. 622; characters of scrofulous sores, i. 622; treatment of the sores must be constitutional, i. 622; occasional disappearance of scrofula at puberty, or during the first pregnancy, i. 622; general treatment of scrofula, i. 623; local treatment of glandular swellings and scrofulous ulcers, i. 623; local treatment of the ulcers when torpid, i. 623; use of iodine and cod-liver oil, i. 623; Lugol on iodine in scrofula, i. 623; Lugol's formulæ for the exhibition of iodine, i. 623; exhibition of cod-liver oil, i. 624; Negrier on fresh walnut leaves and their decoction in scrofula, i. 624; Pollini's decoction, i. 624; Russell and Burns on the treatment of scrofulous ulcers, i. 624; South on the iodide of potassium and cod-liver oil in scrofula, i. 624; scrofulous inflammation of the upper lip, nose, and cheeks, and its treatment, i. 625; *gouty ulcers*, i. 625; causes and characters, i. 625; situation and diagnosis, i. 625; the treatment of these ulcers requires great care, for fear of metastasis, i. 626; general treatment, i. 626; wine of colchicum seeds the most efficacious remedy in gouty and rheumatic affections, i. 626; Lewin's experiments on colchicum as a cause of an increased production of uric acid in the urine, i. 626; local treatment, i. 626; earthy matters deposited in gout, i. 626; *impetiginous ulcers*, i. 627; varieties, i. 627; to be considered as symptoms of chronic eruption of the skin, i. 627; causes of chronic eruptions, i. 627; subdivisions of impetiginous ulcers, i. 627; treatment, general and local, i. 627; *herpetic ulcers*, i. 628; characters, i. 628; varieties of herpes, i. 628; characters of herpes exedens or lupus, i. 628; proximate cause, i.

629; hereditary disposition to herpes, i. 629; remote causes, i. 629; complications with scrofula, syphilis and gout, i. 629; danger of the repulsion or imperfect development of herpes, i. 629; Veiel's division of herpes, i. 629; treatment of herpetic ulcers, i. 630; anti-herpetic medicines, i. 630; external treatment, i. 630; *scalled head or tinea capitis*, i. 631; symptoms and characters of scalled head, i. 631; characters of tinea favosa, i. 631; of tinea granulata, i. 632; of tinea furfuracea, i. 632; of tinea asbestina, i. 632; of tinea muciflua, i. 632; consequences of long-continued scalled head, i. 632; proximate and occasional causes, i. 632; sudden suppression of scalled head sometimes dangerous, i. 632; treatment, i. 632; local treatment, i. 633; *milk crust or crusta lactea*, i. 633; characters, i. 633; of crusta serpiginosa, i. 633; causes of crusta lactea, i. 633; crusta serpiginosa always consequent on complication of crusta lactea with syphilis or herpes, i. 634; Autenrieth's opinion that crusta serpiginosa is connected with itch, i. 634; local and general treatment of crusta lactea, i. 634; of crusta serpiginosa, i. 634; von Wedekind on the treatment of crusta lactea, i. 634; *itch, scabies, or psora*, i. 634; characters, i. 635; characters and causes of itch ulcers, i. 635; Krause on the existence of itch without eruption, i. 635; cause of itch, i. 635; the itch-mite, i. 635; symptoms of scabies spuria, i. 635; Wichmann, Bateman, Baker, Canton, Alibert, Lugol, Renucci, Albin Gras, and Eble on the existence of the itch-mite or acarus scabiei, i. 636; Eble's observation on the acarus, i. 636; Emery and Aube on the contagion of itch, dependent on the itch-mite, i. 636; the inoculation of itch by transplanting the acarus, i. 636; Mouffet, Avenzoar, Joubert, Linnæus, Dr. Adams, and Hyacinth Cestoni on the acarus scabiei, i. 636; Gale's experiment with the itch-mite, i. 637; consequences of neglected itch, i. 637; simple and complicated itch, i. 637; treatment of simple itch, i. 637; objections to greasy applications in the treatment of itch, i. 637; Horn's liniment, i. 638; Fischer on the application of smear, black, or green soap, i. 638; mode of using it, i. 638; symptoms which occur during this treatment, i. 638; treatment of itch by Graf, Vézin, and Pentzlin, i. 639; treatment of itch by liquid sulphuret of lime in the Belgian army, i. 639; treatment of complicated itch, i. 640; of itch ulcers, i. 640; of suppressed itch, i. 640; *venereal ulcers*, i. 640; distinguished as primary and secondary, i. 641; causes, i. 641; South on the inappropriate use of the terms "venereal ulcer" and "chancre" as synonymous, i. 641; John Hunter on the two modes in which the venereal poison affects the system, i. 641; Lawrence on the progress of syphilis from one part of the body to another, i. 642; the operation of the venereal contagion requires a peculiar delicate structure of the part affected, or a deprivation of its cuticle, i. 642; symptoms of chancre, i. 642; characters of the pus secreted by venereal ulcers, i. 642; John Hunter and Ricord on the period at which chancres appear after infection, i. 642; John Hunter on the symptoms of chancre, i. 642; Lawrence on the progress of ulceration in a syphilitic sore, i. 643; Lawrence on the five kinds of syphilitic sores, i. 643; the pus of the ulcer the special vehicle of the venereal contagion, i. 644; Hunter's experiments by inoculating with the matter of gonorrhea and chancre, i. 644; Ricord on inoculation for the purpose of distinguishing syphilitic sores, whether primary or secondary, i. 644; buboes the first symptoms of general syphilis, i. 645; may be idiopathic, or sympathetic, i. 645; symptoms, progress, and terminations, i. 645; John Hunter on the true venereal buboes, i. 645; Ricord on the seven kinds of buboes, i. 645; Hunter and Ricord on the existence of syphilitic buboes, without primary sore, i. 646, 647; general syphilis attacks specially either the skin, mucous membranes, or bones, i. 647; John Hunter on the continuance of the constitutional irritation from lues, independent of continued absorption, i. 647; inflammation of the mucous membrane of the throat, i. 647; symptoms, appearances, and results, i. 647; venereal eruptions, i. 648; symptoms, i. 648; Lawrence on the four kinds of syphilitic eruptions, i. 648; herpetic eruptions, rhagades, verrucæ, and condylomata, i. 649; John Hunter and Ricord on the non-infectious character of the pus from a secondary syphilitic sore, i. 649; symptoms and results of syphilis in the bones, i. 650; modifications of the symptoms of syphilis, i. 650; primary syphilitic ulcers no decided external character, i. 651; Abernethy on pseudo-syphilis, i. 651; Abernethy on the means of distinguishing between true and false syphilis, i. 651; Carmichael's objections to the terms syphilis, syphiloidal, and pseudo-syphilis, i. 652; Carmichael bases his arrangement of venereal complaints on the character of the eruption, i. 652; Ricord on the causes of the varied appearances of chancre or primary syphilitic sore, i. 653; differences in secon-

dary syphilis, i. 654; prognosis, i. 654; John Hunter on the relative rapidity of cure of gonorrhea, chancre, and lues venerea, i. 654; Abernethy on the occasional spontaneous healing of chancre, i. 655; John Hunter on the relapse of ulcers after chancres have cicatrized, i. 655; *treatment of syphilis with mercury*, i. 655; in treating chancre, an especial indication to prevent general syphilis, i. 655; local treatment, i. 655; Ricord on the destruction of the ulcer by the nitrate of silver, i. 655; internal exhibition of mercury, i. 655; Lawrence on the exhibition of mercury in cases of chancre, and on the rarity of the occurrence of secondary symptoms when mercury has been used, i. 656; Lawrence on the extent to which the use of mercury may be pushed, i. 656; Green on the use of mercury in syphilis, and on the forms in which it should be employed, i. 656; circumstances requiring the local exhibition of corrosive sublimate, i. 658; Delpech on frictions with the ung. hyd. cin. in primary syphilis, i. 658; South on the treatment of sloughing chancre, i. 658; mercury not to be used either internally or externally under such circumstances, i. 658; mercury should be exhibited for some time in smaller doses after the chancre has cicatrized, i. 659; treatment of buboes, i. 659; tendency of idiopathic buboes to suppurate, i. 659; treatment of the remaining ulcer, i. 659; treatment of the indurated bubo, i. 659; mode of opening suppurating buboes, i. 659; Ferguson, Fricke, Reynaud, and Ricord on the treatment of buboes, i. 659; South on the treatment of suppurating bubo, and of the subsequent ulcer, i. 659; treatment of general syphilis by mercury, i. 660; external employment of mercury, when required, i. 660; sublimate baths, i. 660; the internal exhibition of mercury preferable in ordinary syphilis, i. 660; local symptoms require special treatment, i. 660; Rust's treatment of syphilitic ulceration of the throat and palate, i. 660; treatment of syphilitic eruptions, i. 660; treatment of the granulations by caustic or the knife, i. 661; of syphilitic diseases of the bones, i. 661; mercurial fumigation in syphilitic ulceration of the tonsils and pharynx, i. 661; South on secondary syphilitic sores and their treatment, i. 661; South on the treatment of nodes, i. 662; necessary to vary the mercurial preparations in use according to constitution and other circumstances, i. 662; Starke on the phosphor. hydrarg., von Graefe on the iodide and bromide of mercury, and Mendaga and Parent on the hydrarg. cyan., i. 662; salivation not necessary for the cure of the venereal disease, i. 662; treatment of salivation, i. 663; treatment of old cases of venereal disease, i. 663; Louvrier and Rust on the friction-cure, i. 663; cases in which the friction-cure is indicated, i. 663; cases in which it is contra-indicated, i. 663; South on the friction-cure, i. 664; mode of employing it, i. 664; Wedemeyer, Rust, and South on the number of times the frictions may require to be practised, i. 664; the order in which the rubbings-in are to be conducted, i. 665; symptoms which occur during this treatment, i. 665; the Montpellier modification of the friction-cure condemned, i. 666; treatment to be adopted, if the salivation or critical sweating be suddenly suspended, i. 666; occurrence of spasmodic or nervous symptoms, i. 666; subsequent treatment, i. 666; Weinhold's mercurial cure, i. 666; mode of employing it, i. 666; Zittmann's decoction, i. 667; mode of exhibiting it, i. 667; formula for Zittmann's decoction, i. 667; the Arabian treatment, i. 668; Dzondi's treatment, i. 668; the preference given to the use of Zittmann's decoction, i. 668; *treatment of syphilis without mercury*, i. 669; various modes of treating secondary symptoms without mercury, i. 669; Pitcairn, Chréstien, and Niel on gold and its preparations in primary and secondary syphilis, i. 669; Ricord, Eusèbe de Salle, Lallemand, Biett, Paillaud, Wallace, Dr. Williams, Judd, Tyrrell, Ebers, von Hasselberg, and Hacker on iodine and hydriodate of potash in gonorrhea and general syphilis, i. 669; Forster on the cure of syphilis by the chloride of gold and soda, i. 670; treatment of syphilis without mercury in England, i. 670; Hill, Hennen, Rose, Guthrie, and Thomson on the duration of the disease under this treatment, and on the subsequent occurrence of secondary symptoms, i. 671; South on the proper mode of exhibiting mercury in the treatment of syphilis, i. 671; objections to the treatment without and with mercury, i. 671; *syphilis in infants*, i. 673; causes of infection, i. 673; Evanson and Maunsell on the communication of syphilis to the fœtus in the womb, i. 673; Huguier on the period at which syphilis shews itself after birth, i. 673; infection of the child by a syphilitic nurse, i. 673; Dyckman's assertion that the child may be infected by the milk of a diseased nurse, i. 673; Hunter, Lawrence, and Todd's cases of diseased children infecting the nurses, i. 673; Colles doubts whether the child can infect the nurse, unless she have ulceration of the nipple, i. 673; Evanson and Maunsell on the symptoms of syphilis in infants, i.

673; Lawrence on syphilitic iritis, and ulceration about the anus in infants, i. 674; prognosis, i. 674; Evanson and Maunsell on the treatment of syphilis in infants, i. 674; Swediaur and Bacot object to the use of corrosive sublimate in such cases, i. 674; Hey, Lawrence, Hunter, Ricord, and South on the possibility of infection from secondary syphilis, i. 675.

Ulna, fracture of, i. 559; dislocation of, i. 789.

Ulnar artery, ligature of, ii. 252.

ULLSAMER on endemic prolapse of the womb from the use of the labour-chair, ii. 108.

Umbilical rupture, ii. 79.

UNDERWOOD on the treatment of ulcers by sticking-plaster, i. 619.

URBAN'S opinion that there is a circlet of small vesicles round the wound or scar in hydrophobia, i. 368.

Ureter, stone in the, ii. 543.

URETHRA, INFLAMMATION OF :—GONORRHEA; causes, i. 155; symptoms and progress, i. 155; chordee, i. 155; balanitis, i. 155; phymosis, i. 155; paraphymosis, i. 155; Hunter and Astley Cooper on the period when gonorrhea first shows itself after infection, i. 156; Astley Cooper, Hunter, and Travers on the primary symptoms, i. 156; Hunter on the specific extent of the inflammation, i. 156; Hunter and Astley Cooper on the actual seat of the discharge, i. 156; Cooper on the post-mortem appearances, i. 157; Hunter on the small swellings which are noticed externally near the urethra, i. 157; Hunter on the size and form of the stream of urine, 157; Hunter and Cooper on the occurrence of hæmorrhage in severe gonorrhea, i. 157; in rare cases the corpus spongiosum is ruptured, i. 157; Macmurdo's case of rupture of a vessel in the penis during coition, i. 157; Hunter on inflammatory and spasmodic chordee, i. 157; Abernethy on permanent chordee from the inflammation having extended to the corpus spongiosum, i 158; Hunter on the extent of local irritation, i. 158; South on retention of urine in severe gonorrhea, i. 158; Hunter on the extension of the inflammation to the bladder, and the consequent inability of that viscus to retain its contents, i. 158; the constitution rarely primarily affected, i. 158; Hunter's case of fever preceding gonorrhea, i. 158; continuance of the symptoms, i. 159; gleet, i. 159; Astley Cooper on the influence of constitutional causes on gonorrhea, i. 159; consequences of gonorrhea, i. 159; seat of, in the female, i. ,159; its propagation to the rectum, i. 159; distinguishing characters from leucorrhea, i. 159; Ricord on acute urethritis in the female, i. 159; Ricord on utero-vaginal gonorrhea, i. 159; Hunter on the extension of the inflammation to the bladder in the female, i. 159; doubts its extension to the ovaries, i. 159; Ricord regards ovaritis as a complication of gonorrhea, i. 159; swelling and infiltration of the external parts, considered by Ricord a kind of phymosis or paraphymosis, i. 159; abscesses in the labia or nymphæ, i. 160; Hunter and Ricord on abscesses complicating gonorrhea, i. 160; distinction between gonorrhea and leucorrhea not easy, i. 160; Dr. Locock on leucorrhea, i. 160; characters of the secretion, i. 160; Locock and Jewel on the distinguishing signs between leucorrhea and gonorrhea, i. 160; pudendal discharges in female infants, i. 161; Locock on the pudendal discharges during dentition, i. 161; Dr. Percival, Dr. Ferriar, Dr. Mackintosh, Kinder Wood, and Capuron on an epidemic vaginal catarrh, i. 161; varieties of gonorrhea, i. 161; Lawrence's division into gonorrhea benigna and gonorrhea virulenta, i. 161; Hunter on gonorrhea from simple causes, i. 161; Sir Everard Home on the internal use of arsenic and ginger as a cause of gonorrhea, i. 162; simple gonorrhea originating in leucorrhea in the female, i. 162; Hunter's case, i. 162; South on gonorrhea virulenta a constitutional disease in certain persons, i. 162; Lawrence's opinion, i. 162; Abernethy on gonorrhea virulenta, i. 162; question of identity between gonorrhea and syphilis, i. 162; observations and experiments of Hernandez and Ricord, i. 162; Becket's memorandum respecting gonorrhea, i. 162; John of Gatesden's Rosa Anglicana, i. 162; John of Arden mentions the *chaude-pisse*, i. 163; the supposed origin of syphilis on the discovery of America, or at the siege of Naples, i. 163; South's opinion that syphilis was known to John of Arden, and perhaps to John of Gatesden, i. 163; Hunter on the identity of the two poisons, i. 163; accounts for the two different effects of the same poison, by the gonorrhea preceding from a secreting surface, while the chancre is formed on a non-secreting surface, i. 163; South on the frequency of the co-occurrence of chancre and gonorrhea, i. 164; Bell denies the identity of gonorrhea and syphilis, i. 164; Hernandez' experiments on the subject, i. 164; the ulcers produced by inoculating with gonorrheal virus are not syphilitic, i. 165; Ricord's observations and experiments, i. 165; Ricord's inferences from the results of the inoculation with gonorrheal matter, i. 165; the opinion that gonorrhea is unattended by ulceration contraverted by

Ricord, i. 166; Travers on gonorrheal sores and their consequences, i. 166; Travers on the secondary symptoms of the gonorrheal sore, i. 166; South on the gonorrheal sore throat, i. 166; diagnosis of the several kinds of gonorrhea, i. 167; the swelling of the testicle, and of the inguinal glands and prostate, sympathetic not syphilitic, i. 167; Hunter on the sympathetic swellings in gonorrhea, i. 167; Cooper on the sympathetic bubo of gonorrhea, i. 167; in all suspicious cases of discharge from the male or female genitals, if the disease be syphilitic, the speculum will shew it in the female, and inoculation with the matter will indicate it in the male, i. 167; Ricord on the examination of public prostitutes, i. 167; treatment, i. 168; Hunter on the duration and spontaneous cure of gonorrhea, i. 168; treatment, i. 168; employment of stimulating injections, i. 169; John of Arden's prescription, i. 169; Beckett's prescription, i. 169; Abernethy's objection to any attempt to check gonorrhea, i. 169; recommends a soothing practice, i. 169; South's treatment, i. 169; Carmichael's injection of a strong solution of nitrate of silver, i. 170; Ricord's treatment by the direct application of the nitrate of silver, i. 170; Astley Cooper's treatment, i. 170; observes that gonorrhea is difficult to cure in strumous subjects, i. 170; treatment of chordee, i. 170; means to check hæmorrhage, if it occur, i. 170; South's treatment of painful erections and chordee, i. 170; Astley Cooper, Ricord, and Hunter on the remedies for chordee, i. 170; South, Hunter, and Ricord on the treatment and arrest of hæmorrhage from the urethra, i. 170; subsequent treatment of gonorrhea, i. 171; treatment of the syphilitic form of gonorrhea, i. 171; treatment of gonorrhea in women, i. 171; South and Ricord on its treatment in women, i. 171; use of stimulating injections in some cases objectionable, i. 171; Home's cases in which the use of stimulating injections caused the sides of the vagina to unite together by the adhesive inflammation, i. 172; Ricord's treatment of severe cases by the introduction of a plug of lint dipped in an emollient narcotic liquid, i. 172; his treatment of obstinate cases by filling the vagina with dry lint, i. 172; ulcerations and papulous granulations to be cauterized, i. 172; Ricord on ulcerations of the mucous membrane of the womb, i. 172; vegetations in the interior of the urethra to be destroyed by incision or cauterization, i. 172; Ricord on gonorrhea in the female urethra, i. 172; treatment of gleet, i. 172; South and Astley Cooper on gleet, i. 173; Astley Cooper, Hunter and South on the infectious nature of gleet, i. 173; Tyrrell's case of protracted gleet, i. 173; Tyrrell on the distinction between gonorrheal gleet, and gleet from stricture, i. 173; Astley Cooper on the distinction between gonorrhea and gleet, and abscess of the lacunæ, i. 173; Astley Cooper on the treatment of gleet, i. 173; constitutional treatment, i. 174; Ricord on inoculation with gonorrhea to cure gleet, i. 174; South's condemnation of that practice, i. 174; use of cubebs, i. 174; Delpech's condemnation of cubebs, i. 174; symptoms produced by the exhibition of cubebs, i. 174; Delpech has shewn that cubebs do not cause inflammation of the testicles, i. 175; Delpech's treatment of gonorrhea, i. 175; Velpeau, Michaelis, Richon, and De Salle on the treatment of gonorrhea, i. 175; Astley Cooper on the use of cubebs in gonorrhea, i. 175; South on cubebs and copaiba in gonorrhea, i. 176; external gonorrhea, balanitis, i. 176; causes and symptoms, i. 176; Hunter and South on balanitis, i. 176; treatment, i. 176; Ricord and South on the treatment, i. 176; gonorrhea of the nose, i. 177; Benjamin Bell's cases, i. 177; treatment of gonorrhea, dependent on a gouty or herpetic disease, i. 177.

URETHRA, rupture of, i. 488. *See* Wounds of the Penis.

URETHRA, STRICTURE OF, ii. 351; stricture of the urethra of more frequent occurrence than in any other outlet, ii. 352; symptoms, ii. 352; Brodie on incontinence of urine in stricture, ii. 352; extravasation of urine from rupture or sloughing of the urethra behind the stricture, ii. 353; Brodie on extravasation of urine from ruptured urethra in stricture, ii. 353; Brodie on abscesses communicating with the bladder in old cases of stricture, ii. 353; changes in the urethra in old strictures, and the attendant symptoms, ii. 353; Brodie on the complication of stricture with enlarged prostate, ii. 354; Brodie's case of enlargement of the urethra from stricture, ii. 354; Brodie on the formation of cysts of the urethral mucous membrane in stricture, ii. 354; Brodie on the occurrence of rigors and fever in cases of stricture, ii. 354; causes of stricture, ii. 355; Brodie on the existence in old strictures of an indurated mass at the lower portion of the penis, ii. 355; seat and characters of stricture, ii. 355; Hunter's description of three forms of stricture, ii. 356; Brodie on the original seat of stricture, ii. 356; diseases liable to be confounded with stricture, ii. 356; diagnosis, ii. 357; prognosis, ii. 357;

treatment ii. 357; mode of determining the seat of the stricture, ii. 357, 358; Brodie on the use of a full-sized bougie in determining the seat of the stricture, ii. 357; preparation of common bougies, ii. 358; Astley Cooper, Abernethy and Brodie on passing the bougie, ii. 359; Astley Cooper and Abernethy on the use of metallic bougies, ii. 359; Brodie on the treatment of stricture with bougies, and on their applicability to the respective kinds of stricture, ii. 360; Brodie's directions for the introduction of the bougie, ii. 360; South on the danger of using plaster bougies, ii. 361; South on the introduction of the bougie, ii. 362; South on the general treatment of stricture, ii. 363; the time the bougie should be left in the urethra, and the frequency of its introduction, ii. 363; precautions to be taken when the instrument is left in the urethra, ii. 364; gradual increase in the size of the instrument used, ii. 364; Arnott's oil-silk tube, ii. 364; action of the bougie, ii. 364; symptoms occasionally produced by it, ii. 364; Astley Cooper and Abernethy on hæmorrhage from the urethra after passing the bougie, ii. 365; Astley Cooper and South on the practice to be adopted when a laceration of the urethra by the bougie is suspected, ii. 365; destruction of the stricture by caustic, ii. 365; by ulceration to be rejected as dangerous, ii. 365; Brodie on the destruction of stricture by ulceration, ii. 365; cauterizing a stricture from before backwards, ii. 366; preparation of armed bougies, ii. 366; Hunter, Home and Whately on the use of the armed bougie, ii. 366; objections to this mode of cauterization, ii. 366; cauterizing the walls of the stricture, ii. 366; Whately and Arnott on cauterizing the walls of the stricture, ii. 367; use of bougies armed with caustic potash, ii. 367; Whately and Lawrence on the use of bougies armed with caustic potash, ii. 368; Ducamp's mode of cauterizing the urethra, ii. 368; subsequent treatment, ii. 369; Ducamp's mode of dilating the urethra after cauterization, ii. 369; Ducamp's caution respecting the use of caustic, ii. 370; Lallemand, Segalas and Tanchou's caustic-holders, ii. 370; relative advantages of the treatment by bougies and by caustic, ii. 370; Astley Cooper, Brodie, Lawrence and South on the use of the armed bougie, ii. 371; cutting into the stricture, and subsequent dilatation, ii. 372; Jameson's treatment of stricture, ii. 372; formation of false passages, ii. 373; treatment, ii. 373; South on the treatment of false passages, ii. 373; congenital closure of the urethra, ii. 373; treatment, ii. 373.

Urethra, calculus in the, ii. 630.

Urinary fistula, i. 737.

Urine, retention of, ii. 409.

Urethroplasty, i. 742.

Uvula, relaxation of, i. 147; extirpation of, i. 147.

VACCINATION OR INOCULATION WITH COW POCK, ii. 873; definition, ii. 873; use of the lymph, ii. 873; Dr. Gregory on the origin of vaccination, ii. 873; Dr. Jenner's discovery, ii. 873; Cline, the first experimenter, ii. 873; Dr. Gregory on the preservation of vaccine lymph for transmission, ii. 874; Gregory on the period at which lymph should be taken for vaccination, ii. 874; vaccination an operation without danger, ii. 874; mode of vaccinating from a fresh pustule, ii. 874; Dr. Gregory on the operation of vaccination, ii. 874; vaccination with dry matter, ii. 874; appearances after effectual vaccination, ii. 874; Gregory on the appearances after effectual vaccination, ii. 875; irregularities in the course of the vaccine vesicle, ii. 875; Gregory on the insusceptibility of some constitutions to the vaccine virus, ii. 876; after-treatment, ii. 876; Gregory on the appearance of vaccine lichen, ii. 876.

Vagina, wounds of, i. 486; prolapse of, ii. 122; closure, and narrowing of, ii. 374; polypus of, ii. 754.

Vaginal rupture, ii. 89.

VALENTIN on the exudation-corpuscles, i. 34; microscopic characters of pus, i. 35; microscopic results of suppuration, i. 37; mode of amputating by the circular incision, ii. 891.

Valgus, ii. 185.

VALSALVA on the lengthening of the limb in hip-disease, i. 257.

Varicose aneurism, ii. 271.

Varix, aneurismal, ii. 268.

VARICES:—definition, ii. 287; characters, ii. 287; Brodie on the effects of inflammation on the blood in veins, ii. 287; Hodgson and Petit on the coagula in varicose veins, ii. 288; causes, ii. 288; Dr. Baillie's case of obliterated vena cava inferior, ii. 288; Brodie's case of varicose veins of the fore-arm, ii. 289; Cline's case of obliteration of the inferior vena cava, ii. 289; Brodie's cases of varicose veins of the arm and chest from compression of the subclavian veins, ii. 289; Petit and Velpeau's cases of varices in the upper extremities, ii. 289; South and Cline's cases of varix of the deep-seated veins, ii. 289; treatment, ii. 290; Brodie on the application of adhesive plasters in the treatment, ii. 290; radical cure, ii. 290; Gottschalk on the treatment of varix, ii. 290; puncture with a lancet, ii. 290; incision, ii. 291; extirpation, ii. 291; application of the ligature, ii. 291; Ricord on the application of the ligature, ii. 291; Sir E. Home and South on the ligature of the saphena for varix, ii. 291; Solera's operation by cutting through the vein above and below, ii. 292; Brodie on the subcutaneous division of the vein, ii. 292; application of the actual or potential cautery, ii. 292; Bonnet, von Froriep, Mayo, and Brodie on the application of caustic, ii. 292; introduction of needles through the walls of a vein, ii. 292; modes of operating, ii. 292; Velpeau on the introduction of needles, ii. 293; lateral compression of the vein, ii. 294; occasional consequences of operations on varicose veins, ii. 294; *varicocele* or *cirsocele*, ii. 295; definition and characters of the disease, ii. 295; Breschet and South on spermatocele, ii. 295; causes of, ii. 296; Morgagni, Astley Cooper and Lenoir on the causes of, ii. 296; consequences, ii. 296; treatment, ii. 296; operations for the radical cure, ii. 297; Charles Bell and Delpech on the ligature of the spermatic veins, ii. 297; Maunoir on the ligature of the spermatic artery, ii. 297; Fricke, Kuh, Davat, Franc, Raynaud, Wormald, A. Cooper, Lehmann, and Breschet's operations, ii. 297; estimate of the relative value of these operations, ii. 298; mode of performing Breschet's operation, ii. 299; after-treatment, ii. 299; *hæmorrhoids* or *piles*, ii. 300; definition and varieties, ii. 300; situation and consequences, ii. 300; Bushe on the local symptoms of piles, ii. 301; Bushe on the effects of the loss of blood from piles, ii. 301; causes, ii. 301; treatment, ii. 301; extirpation, ii. 302; Rousseau and Delpech's mode of extirpating piles, ii. 302; Copeland, Brodie, Bushe, and Syme on the removal of internal piles by ligature, ii. 302; Petit, Kirby, and Brodie's cases in which severe symptoms followed the use of the ligature for piles, ii. 303; Copeland and Brodie on the application of the ligature, ii. 303; extirpation of degenerated piles, ii. 303; consecutive hæmorrhage, symptoms and treatment, ii. 304; Bushe on the treatment of the consecutive hæmorrhage, ii. 304; Cline, Cooper, and Brodie on excision of piles, ii. 304.

Varus, ii. 174.

VEIEL's division of herpes, i. 629.

VEITCH's mode of amputating at the hip-joint by the circular cut, ii. 934.

VELPEAU's treatment of erysipelas by moderate compression, i. 108; on pressure in the treatment of burns, i. 116; considers it best adapted to cases of burn in the third and fourth degrees, but also applicable to those of the second, i. 117; mode of applying compression, i. 117; advantages of this plan of treatment, i. 117; treatment of gonorrhea, i. 175; of complete anchylosis, i. 247; on the three operations for the relief of bony anchylosis, i. 247; consequences of the adhesion of the knee-pan to the condyles of the femur, i. 248; objections to the use of Louvrier's apparatus, i. 249; torsion of arteries, i. 308; treatment of artificial anus connected with the cæcum, i. 725; case of simple dislocation of the sternal end of the clavicle inwards and backwards, i. 779; primitive direction of dislocation of the humerus, i. 782; operation for prolapsus uteri, ii. 112; modification of Hey's operation for prolapse of the rectum, ii. 135; acupuncture of the artery in aneurism, ii. 228; ligature of the external maxillary or facial, ii. 239; case of varix in the upper extremity, ii. 289; introduction of needles in the treatment of varix, ii. 293; injections of iodine in hydrarthrus, ii. 463; hydrocele caused by gonorrhea, ii. 499; mode of amputating at the knee with the circular cut, ii. 944; at the ancle-joint, ii. 944; mode of operating in exarticulation of the fore-arm at the elbow, ii. 962; operation in excision of the wrist, ii. 977.

Venesection, ii. 860.

Ventral rupture, ii. 84.

VERDIER's artery-compressor, i. 299.

VERING's objection to the union of penetrating wounds of the chest, i. 449.

VERMANDOIS on the lengthening of the limb in hip-disease, i. 257; excision of the carious head of the femur in hip-disease, i. 270; experiments on the excision of joints, ii. 969.

Vertebral artery, ligature of, ii. 249.

Vertebræ, fractures and dislocations of, i. 531; dislocations of, i. 772.

Vesico-vaginal fistula, i. 750.

VÉZIN on the treatment of itch, i. 639.

VIBORG on the treatment of salivary fistula, i. 713.

VIDAL's proposal to occlude the vulva in complete destruction of the vagina and wall of the bladder, i. 759; surgical treatment of dislocation of the thumb from the metacarpal bone, i. 794; cause of the difficulty experienced in reducing this dislocation, i. 795; operation for the division of the inner fold of the prepuce, ii. 347.

VIGAROUX's case of excision of a joint, ii. 968.

VIGNOLO on simultaneous dislocation of the radius forwards, and of the ulna backwards, i. 791.

VIGUERIN's mode of treating congenital hydrocele, ii. 508.

Villaumé on dislocation of the upper end of the radius forwards, i. 791.

Villermé on the reunion of fractures, i. 500; double formation of bony substance in fracture, i. 501; production of callus, i. 501.

Vincent's fatal case of viper-bite, i. 353; case of calculi in the perineum, ii. 632; of calculi between the prepuce and glans penis, ii. 633.

Voelter on the use of the suture in vesico-vaginal fistula, i. 753.

Vogel on the phenomena of inflammation under the microscope, i. 30; formation of pus, i. 35; effects of the resorption of pus, i. 36; noma, i. 61: essential element of medullary fungus, ii. 722; blood-fungus, ii. 722.

Vohler's mode of amputating at the hip-joint with two flaps, ii. 939.

Voillemier's case of dislocation of the wrist, i. 792; diagnostic signs of dislocation of the wrist, and fracture of the lower end of the radius, i. 792.

Volpi has not found benefit from the actual cautery, when the first symptoms of hip-disease occurred at the knee and not at the hip, i. 265; case of reduction of the consecutive dislocation in hip-disease, i. 268; apparatus for fracture of the neck of the femur, i. 569.

Wachter's experiments on the excision of joints, ii. 969.

Wagner's, Dr. cases of malignant pustule, produced by contact and by eating the flesh of diseased animals, i. 66.

Wallace, Dr. on hydriodate of potash in syphilis, i. 669.

Wallner's treatment of fracture of the lower jaw, i. 529.

Walshe, Dr. on the genus carcinoma, ii. 716.

Walther's, von, plan of opening a cold abscess with a seton, i. 90; treatment of fistulous passages, i. 93; seat of boils originally in the sebaceous glands of the skin, i. 132; incisions in carbuncle, i. 137; after-management of ligatures on arteries, i. 306; symptoms of laceration of the brain, i. 410; employs trepanning in injuries of the head only when secondary symptoms of irritation and pressure require it, i. 412; objection to dressing the wound after the operation for rectal fistula, i. 731; simultaneous dislocation of both inferior oblique processes of one of the cervical vertebræ, i. 773; nature of strangulation in ruptures, ii. 11; incision of the hernial sac, and the introduction of lint-tents for its radical cure, ii. 24; formation of urinary calculi, ii. 514; origin of oxalic acid in the urine, ii. 519; fungus of the dura mater, ii. 685; objections to operating for fungus of the dura mater, ii. 688; difference between fungus hæmatodes and sarcoma medullare, ii. 721; ligature of the spermatic artery in sarcocele, ii. 811; case of excision of the cervix uteri preceded by excising the pubic arch, ii. 822; management of the periosteum in amputations, ii. 893; mode of amputating at the hip-joint with two flaps, ii. 939; mode of operating in partial amputation of the foot preferred, ii. 948; in amputation at the shoulder-joint by an upper and an under flap, ii. 955; in exarticulation of both middle metacarpal bones, ii. 965; case of excision of part of the hand, ii. 965; mode of operating in resection of the scapula, ii. 1002.

Wantzel on the causes of club-foot, ii. 176.

Ward's, Dr. application of flour in the treatment of burns, i. 115; mode of application, i. 115; objection to liquid applications, i. 115; modus operandi of the flour, i. 116.

Wardenburg's apparatus for fractures of the olecranon, i. 560.

Wardrop on ingrowing of the nail, i. 198; on onychia maligna, i. 202; evulsion of the nail in the treatment of that disease, i. 203; internal treatment in onychia maligna, i. 203; Brasdor's operation, ii. 230; treatment of branching aneurism, ii. 275; proposal to bleed a patient to fainting, and operate during the syncope, ii. 855; case of excision of part of the lower jaw without the condyle, ii. 988.

Warner's case of abscess mistaken for aneurism, ii. 201.

Warren's, Dr. plan for bringing the edges of the cleft together in staphyloraphy, i. 605; operation when the cleft is very large and complicated, i. 606; treatment to be adopted when air enters a vein during an operation, ii. 856; case of resection of the clavicle, ii. 1004; of a rib, ii. 1006; employment of ether by inhalation prior to the performance of important surgical operations, ii. 1007.

Warts, ii. 667.

Wasserfuhr's operation and apparatus for re-breaking a badly-united bone, i. 525.

Watson, Dr. on the local treatment of quinsy, i. 140; cases in which the carotid artery or a branch was wounded in scarifying the tonsils, i. 141; difference between synovial inflammation and inflammation of the ligaments, i. 216; objections to Marochetti's views respecting hydrophobia, i. 376; cases of hæmorrhage during the operation of tapping, ii. 485.

Wattmann's treatment of fractured clavicle, i. 551; method of replacement of the dislocated femur, i. 798; operation on the humerus in anchylosis of the elbow, ii. 311.

Weber's experiments show that the head of the thigh-bone is retained in its socket by atmospheric pressure, i. 257; of great importance in reference to diseases of the hip-joint, i. 257; on the production of callus, i. 501.

Webster's case of dislocation of the ribs, i. 776.

Weckert's apparatus for fracture of the neck of the femur, i. 570.

Wedekind, von, on the treatment of crusta lactea, i. 634.

Wedemeyer on the number of times frictions with ung. hydrarg. may require to be practised in syphilis, i. 664; case in which the aneurism burst after the ligature of the femoral, and amputation was performed, ii. 223.

Weidmann's apparatus for ligaturing complete rectal fistulæ, i. 733.

Weilinger on the use of caustic to destroy the ends of broken bone in false joints, i. 590.

Weinhold on the introduction of the seton in false joints, i. 593; mercurial cure in syphilis, i. 666; cloacæ in necrosis, i. 694; case of old dislocation of the humerus, to reduce which the tendon of the pectoralis major was divided, i. 786; operations in disease of the maxillary cavity, ii. 744.

Welbank on sloughing phagedena, i. 70; case of part of a vertebra and rib in the rectum, ii. 392.

Wells', Dr. case of epilepsy consequent on fissure of the skull, relieved by the trephine, i. 416; of an aneurism bursting into another artery, ii. 199.

Wend on the treatment of abscesses at the hip, i. 269.

Wenzel's diagnostic sign for vertebral caries, i. 281; on extirpation of the womb, ii. 823.

Wernecke's plan for bringing the edges of the cleft together in staphyloraphy, i. 605; instrument for drawing the knots, i. 605; operation for considerable narrowing of the mouth, ii. 316.

Wernherr on morbus coxæ senilis, i. 260.

West on the extirpation of the ovary, ii. 487; case of extirpation of ovarian cyst, ii. 489.

Wetzlar on the formation of urinary calculi, ii. 513; treatment of uric acid gravel, ii. 534.

Whately on the use of the armed bougie in stricture of the urethra, ii. 366; cauterizing the walls of the stricture, ii. 367; use of bougies armed with caustic potash, ii. 368.

White's operation for resection of the carious head of the femur in hip disease, i. 270; case of cure of ununited fracture, i. 591; compensating collateral branches after ligature of the brachial, ii. 254; operation for ligature of the internal iliac, ii. 257; seat of stricture in the rectum, ii. 336; case of foreign body in the vagina, the bladder injured, and formation of a calculus, ii. 524; amputation just above the ancle, ii. 921; operations for the excision of joints, ii. 968; case of excision of the head of the femur, ii. 978, 979; of compound dislocation of the femur behind the leg, ii. 982; of excision of the lower jaw, ii. 991.

White, C. on sawing off the ends of the broken bone in false joint, i. 592; mode of operating in excision of the head of the humerus, ii. 974; excision of the head of the femur, ii. 979.

——'s, Dr. case of almost complete extirpation of the upper jaw, ii. 994.

White swelling, i. 274.

Whitlow, i. 192.

Wickham on inflammation of the ligaments, i. 207; disease of the cellular membrane of the joints, i. 210; case of synovial inflammation terminating in ulceration, i. 214; of trepanning the spine, i. 538; of urinary calculus enclosed in a bag of lymph encrusted with calcareous matter, ii. 548; of bronchocele, which ultimately enlarged, after the ligature of the superior thyroid, ii. 659.

Wickmann on the existence of the acarus scabiei, i. 636.

Wieseman on cauterizing the tonsils with the red-hot iron or caustic, i. 145.

Willan, Dr. on eczema rubrum, i. 678.

Wilhelm on the nature of strangulation in rupture, ii. 11; mode of amputating by the circular incision, ii. 891.

Williams', Dr. stimulant plan of treatment in simple erysipelas, i. 106; on hydriodate of potash in syphilis, i. 669.

Williams' experiments and conclusions on the condition of the lungs when the chest is opened, i. 439.

Willis, Dr. on the formation of urinary calculi, ii. 513.

Wilson on inflammation of cartilage, i. 228; the ulcerative absorption of cartilage, i. 228; on sebaceous tumours, ii. 698; case of division of a nerve wounded in bleeding, ii. 887.

Wilson's, Erasmus, statistical account of human horns, ii. 669; growth of horns from a previously obstructed follicle, ii. 670.

Winslow on increased pressure and the supine posture in the radical cure of hernia, ii. 23.

Winter's, von, case of reduction of the consecutive dislocation in hip-disease, i. 268; directions for wounded arteries, i. 301.

WISEMAN on incisions in carbuncle, i. 137; immediate amputation in gun-shot wounds, i. 345; spina ventosa, ii. 679.

WOLF on twisting round of the patella, i. 805.

WOLF'S, LAUD, case of extirpation of the cancerous womb, ii. 824.

WOLFF'S case of imperforate anus, ii. 325.

Womb, abscess of, i. 484; prolapse of, ii. 103; closure and narrowing of the mouth of, ii. 377; polypus of, ii. 746; cancer of, ii. 817; extirpation of the neck of, ii. 821; of the whole organ, ii. 823.

WOMB, CHANGED DIRECTION OF, ii. 138:—changes of direction to which the womb is subject, ii. 138; *retroversion*, ii. 139; Dr. Rigby on retroversion in the unimpregnated state, ii. 139; Dr. Blundell on the local symptoms caused by retroversion, ii. 139; predisposing and occasional causes, ii. 139; symptoms of the chronic inflammation which precedes retroversion, ii. 139; symptoms of retroversion, ii. 140; Mende on the seeming retroversion at the later periods of pregnancy, ii. 140; Blundell on partial retention of urine in retroversion, ii. 140; Lacroix on the nervous symptoms attending sudden retroversion, ii. 140; situation of the womb as ascertained by vaginal examination, ii. 140; Rigby on examination by the vagina and rectum, and by the uterine sound in retroflexion, ii. 141; symptoms of retroversion, ii. 141; Rigby on the symptoms of, ii. 142; prognosis, ii. 142; Blundell on the prognosis in, ii. 142; treatment, ii. 143; catheterism, ii. 143; exhibition of enemata, ii. 143; reduction of the retroverted womb, ii. 143; Bellanger and Halpin on the reduction, ii. 144; Jourel and Baynham's cases of puncturing the womb in, ii. 144; the replacement of the retroverted womb *per vaginam* preferable, ii. 144; treatment in women not pregnant, ii. 144; after-treatment, ii. 145; Rigby on the mechanical support to the womb requisite after reduction, ii. 145; *anteversion of the womb*, ii. 146; causes and symptoms, ii. 146; Blundell, John Burns, Boivin, Dugés, and Gray on anteversion, ii. 146; treatment, ii. 147; Boivin and Dugés' cases of spontaneous cure, ii. 147; Godefrey's cases cured by position, ii. 147; *antroversion of the womb* in the unimpregnated state, ii. 147; causes, ii. 148; reduction, ii. 148; Gray on Hull's utero-abdominal supporter, ii. 148.

WOMB, WOUNDS OF, i. 482:—the unimpregnated womb not easily wounded, i. 482; danger of injury to the impregnated womb, i. 482; if the wound in the womb be so large, that the fœtus is partially or wholly in the abdomen, it must be extracted, i. 482; Duparcque on the fibrous and cartilaginous resistance of the tissue of the womb, i. 482; Latour and Duparcque's cases of accumulation of blood in the womb, i. 483; Duparcque on rupture of the womb during pregnancy, i. 483; Duparcque on the danger and immediate treatment of rupture, i. 483; Powell's case of rupture not fatal, i. 484; Dr. Rigby and Dr. Merrem on wounds of the uterus as predisposing to rupture in subsequent labours, i. 484; Birch's case of fatal rupture, subsequently to one previously recovered from, i. 484; Merrem's explanation of this, i. 484; Duparcque on partial rupture of, from a collection of fluid in its parietes, i. 484; Morère and Duparcque's cases of abscess of the womb, i. 484; rupture of the impregnated womb from external violence, i. 485; Naëgele's jun. case of womb in the eighth month of pregnancy ruptured by external violence, i. 485; Duparcque on punctures or narrow lacerations of the womb, i. 486; Planchon's case of fatal punctured wound, i. 486; Deneux and Schmucker's cases of wounds, i. 486; *wounds and ruptures of the vagina*, i. 486; causes, i. 486; consequences, i. 486; South on rupture of the perineum, i. 486.

WOOD, Dr. on the chemical and microscopic characters of pus, i. 35.

WOOD, KINDER, on an epidemic vaginal catarrh, i. 161; operation of excising a portion of the tunica vaginalis in hydrocele, ii. 502.

WOOLASTON'S, Dr. C. cases of gangrene, i. 61.

WORMALD'S operation for varicocele, ii. 297.

WOUNDS:—definition of, i. 286; varieties of, i. 286; South on the German distinction between incised wounds, i. 287; wounds distinguished as simple and complicated, i. 287; also according to their direction and depth, i. 287; also by the nature of the divided parts, i. 287; symptoms, i. 287; consequences of, i. 287; inflammation and sympathetic fever, i. 288; nervous symptoms attending wounds, and their causes, i. 288; Hunter and Meckel on the three kinds of union of divided parts,—quick union, by adhesion, and by granulation, i. 288; Hunter on quick union, i. 288; objected to by Dr. John Thomson, i. 288; Astley Cooper on the union of wounds, i. 289; Travers on the blood as a medium of organized adhesion in, i. 289; quick union, i. 289; South on the meaning of "quick union," i. 290; Hunter on the adhesive inflammation in connexion with wounds, i. 290; Astley Cooper on adhesive inflammation, i. 290; Dr. Bennett and Wharton Jones on the process of union by adhesion, i. 290;

Lawrence's objection to the term "inflammation" in reference to union by adhesion, i. 291; Bennett on the formation of new vessels, i. 291; opinions of John Hunter, Schwann, Doellinger, Kaltenbrunner, Pockels, Liston, Travers, Hasse, Henle, Skoda, and Kolletschka, i. 292; union by granulation, i. 292; nature of the cicatrix, i. 292; John Hunter on suppuration and granulation as leading to cicatrization, i. 292; Travers on the filling up a gaping wound, i. 293; Bennett on the process of granulation and cicatrization, i. 294; Wharton Jones on healing by the second intention or granulation, i. 294; points to be noticed in the prognosis, i. 294; treatment, i. 295; examination of wounds, i. 295; treatment of the bleeding, i. 296; mode of arresting hæmorrhage adopted by nature, i. 296; changes in the blood-clot in the canal of the artery; i. 296; Petit, Morand, Sharp, Gooch, Kirkland, Pouteau, John Bell, Textor, and Hummel on the arrest of hæmorrhage by nature, i. 297; wounds of arteries and their consequences, i. 297; closure of slight [illegible]d longitudinal wounds, i. 298; Saviard, Petit, and Scarpa on the healing of wounds of, i. 298; means for arresting hæmorrhage, i. 298; compression, i. 298; Ehrlich's compressor, i. 298; the tourniquet, i. 298; different kinds of tourniquets, i. 298; mode of applying the tourniquet, i. 299; South on the application of, i. 299; the artery-compressors of Langenbeck, Verdier, Mohrenheim, Dahl, Wegenhausen, Moore, Graefe, Scultetus, Heister, Dionis, Plattner, Brambilla, Desault, Liber, Ayres, Bell, Chabert, Lampe, Faulquier, Schindler, Hesselbach, and Joachim, i. 299; Carlisle's tourniquet, and its mode of application, i. 300; the ring tourniquet, i. 300; Oke's arch tourniquet, i. 300; use of the compressor cannot be persisted in sufficiently long, i. 300; treatment of wounds after the bleeding has ceased, i. 300; von Winter's directions for wounded arteries, i. 301; immediate or direct compression, i. 301; South on the treatment of protracted oozing of blood, i. 301; pressure on the meningeal artery inadmissible and not requisite, i. 301; Abernethy's case of wounded meningeal artery, i. 301; South on the treatment of epistaxis, i. 302; South on wounds of the pudic artery, and artery of the bulb during the lateral operation for the stone, i. 302; South on the treatment of wounded arteries in the thick fleshy parts of the hand or foot, i. 302; ligature of arteries, i. 303; experiments of Jones, Crampton, and Scarpa on the ligature of, i. 303; South's experiment on the carotid of a dog, i. 303; difference of opinion as to the action of the ligature, i. 303; English surgeons so apply the ligature, as to divide the inner arterial coat, i. 303; Cline's experiment with the broad ligature, i. 304; Scarpa's experiment with the ligature and cylinder of linen, i. 304; Manec, Dupuytren, and Roux on the introduction of a piece of bougie into an ossified artery after amputation, i. 304; experience in favour of the simple round ligature, i. 304; application of the ligature, i. 304; varieties of forceps for holding the artery i. 304; South on the application of the ligature, i. 304; treatment of a retracted artery, i. 305; South on the ligature of large arteries above and below the wound, i. 305; South on the necessity for cutting down upon a wounded vessel on the sound side of a limb, if nearer the artery than is the part wounded, i. 305; Travers' case of wound of the posterior tibial, i. 305; after-management of the ligature, i. 305; Lawrence, Hennen, Delpech, Walther, Haire, Guthrie, and South on the after-management of, i. 306; Dr. M'Sweeny on the silk-worm gut ligature, i. 307; Physick on the animal ligature, i. 307; Astley Cooper on the catgut ligature, i. 307; length of time before the separation of a ligature, i. 307; Callaway and Guthrie's cases, i. 307; severe pain caused by attempts to take away the ligature, a nerve being included in the noose, i. 307; Chopart's case, i. 307; Lord Nelson's case, i. 307; secondary hæmorrhage on the separation of the ligature, i. 307; Green's case of secondary hæmorrhage after ligature of the subclavian, i. 307; South's opinion that the ligature should be allowed to come away, as the result of the suppurating process, i. 308; South on the management of a long-retained ligature, i. 308; torsion or twisting of arteries, i. 308; Galen, Amussat, Thierry, Liber, Velpeau, Fricke, and Dieffenbach on torsion, i. 308; changes produced by, i. 308; John Hunter on the suppression of hæmorrhage, i. 309; Palmer on torsion, i. 309; Amussat, Thierry, and Fricke on the mode of practising torsion, i. 309; Dieffenbach's torsion-forceps, i. 310; Kluge's torsion-apparatus, i. 310; advantages of torsion, i. 310; Dupuytren, Lorch, Textor, Fricke, Elston, and Bramberger on the effects of, i. 311; Dieffenbach, Dupuytren, and Chelius' objections to, i. 311; South on, i. 311; Ferne and Astley Cooper's cases of accidental torsion, i. 311; cases in which torsion is preferable, i. 311; Köhler and Fricke on the torsion of bony vessels, i. 311; Stilling on the interweaving of arteries, i. 311; use of astringent styptics, i. 312; effects of cauterization on wounded vessels, i. 313; occurrence and management of secondary hæmorrhage, i. 313; circumstance favouring the occurrence of secondary hæmorrhage, i. 313; Cline's, jun. cases of after-bleeding, in which the actual cautery was employed, i. 314; Cline's, jun. clinical observations on after-hæmorrhage, and on the use of the actual cautery in such cases, i. 316; Cline's, jun. experiments on arteries, i. 318; South on the treatment of bleeding ossified arteries, i. 318; bleeding from wounded veins, i. 318; indications of venous hæmorrhage, i. 318; bleeding from the smaller veins usually stops of itself, from the large ones, such as the internal jugular, the subclavian, and the femoral, is soon fatal, i. 319; compression usually employed to arrest venous hæmorrhage, the ligature rarely, i. 319; disadvantages of the ligature, i. 319; South on venous bleeding in operations, i. 319; South's case of fatal venous bleeding during amputation of the breast, i. 319; Green's case of ligature of the external jugular vein, i. 319; use of the ligature by Celsus, i. 320; Thomas Gale and Paré on the use of the ligature for wounded vessels, i. 320; invention of the tenaculum by Bromfield, i. 320; removal of foreign bodies from wounds, i. 322; great care required in doing so, i. 322; condition of the wound a guide as to the treatment, whether for quick union, or by suppuration and granulation, i. 322; the cleaner the wound, the more is it disposed for quick union, i. 322; slight bruises may admit of quick union, but those with the greatest degree of bruising and tearing do not, i. 322; simultaneous injury of the bone does not counter-indicate union, i. 322; deleterious matter in the wound counter-indicates union, i. 323; treatment of a wound to induce union, i. 323; Hunter on the means for keeping the lips of a wound in apposition, i. 323; position of the wounded parts, i. 323; uniting bandages, i. 323; application of the bandage, i. 323; South on the use of bandages for wounds, i. 324; application of sticking-plaster to keep the lips of wounds in apposition, i. 324; Gale on dressing wounds, i. 324; John Hunter on the use of sticking-plaster or the dry suture for wounds, i. 325; Tyrrell and Liston's plasters, i. 325; cases in which the suture should be used, i. 325; John Hunter on the use of sutures, i. 325; South on the advantages and disadvantages of sutures, i. 326; South on the number of sutures to be used, and the mode of their application, i. 326; Dieffenbach's thin insect-pins and the twisted suture, i. 327; varieties of suture, i. 327; application of the interrupted suture, i. 327; Gale on the application of the interrupted suture, i. 328; the quill suture, i. 328; dressing the wound after the application of sutures, i. 328; subsequent treatment, i. 328; treatment of a wound healing by suppuration and granulation, i. 328; South's objections to stuffing a wound which must heal by suppuration, i. 329; *incised wounds*, i. 329; longitudinal and transverse wounds of tendons, i. 329; mode of union of transverse wounds, i. 329; treatment of wounded tendons, i. 329; Ever's apparatus for divided and ruptured tendons of the hand and fingers, i. 330; effects of the division of a large nerve, i. 330; South on the regeneration of nerves, and the recovery of their function after division, i. 330; Haighton's experiments on the division of both pneumo-gastric nerves, i. 330; Meyer on the application of nitric acid to the scar of nerves, i. 330; Larrey on the union of the nerves of a stump in loops, i. 330; treatment of flap wounds, i. 331; reunion of separated parts, i. 331; *punctured wounds*, i. 331; definition, i. 331; treatment, i. 332; punctured wounds of parts of tough structure, or surrounded by unyielding aponeuroses, i. 332; punctures of tendons, i. 332; of nerves, i. 332; treatment of punctured wounds of nerves, i. 332; of punctured vessels, i. 332; enlargement of a punctured wound only necessary for the removal of foreign bodies, to arrest hemorrhage, or to relieve strangulation in parts of an unyielding texture, i. 333; the introduction of a seton to be practised only when the walls of the fistulous passage are callous, i. 333; *lacerated and contused wounds*, i. 333; definition and character, i. 333; union to be attempted only in wounds without much bruising or tearing, i. 333; generally heal by suppuration and granulation, i. 333; treatment, i. 333; removal of foreign bodies, i. 333; South on the tearing or stripping down of large pieces of skin, i. 333; South on torn wounds of the scalp, i. 334; South on the sloughing which generally follows extensive laceration of the skin of the limbs, i. 334; bruises with extravasation of blood, i. 334; treatment, i. 334; if a large artery be wounded, it may be necessary to expose it, and take it up, i. 334; if suppuration take place in the swelling, it must be trèated as an abscess, i. 334; South on extensive ecchymosis, and the means of diagnosis, when an artery of any material size is wounded, i. 334; treatment of the swelling, i. 334; danger of gangrene when a large artery has been wounded, from the distension of the soft parts, i. 334; *gun-shot wounds,* i. 335; definition, i. 335; John Hunter on gun-shot wounds, i. 335; Dupuytren on the effects of gun-shot, i. 336; Dupuytren's case of a person killed by a gun loaded with powder only, i. 336; South's cases of severe injury from small shot, i. 336; pain and hæmorrhage attendant on a gun-shot wound, i. 337; form of the wound, i. 337; shock from the wound, i. 337; subsequent symptoms, i. 337; Guthrie on the pain attending gun-shot wounds, i. 337; Guthrie on the attendant hæmorrhage, i. 337; Guthrie and Hennen on the shock caused by a gun-shot wound, i. 338; Hunter on the character of gun-shot wounds, i. 338; H. Larrey's cases of regular-shaped gun-shot wounds, i. 338; direction of the shot, i. 339; general kinds of injury from shot wounds, i. 339; division of shot wounds into simple and complicated, i. 339; Rust and Busch's explanation of wounds from the wind of the ball, i. 339; Hennen on severe bruising from shot, i. 339; Guthrie on the appearances caused by the passage of a ball, i. 339; Dr. Thompson and Dupuytren on the splitting of the ball by the sharp edge of a bone, i. 339; Guthrie on the resistance offered to the passage of the ball by bone or an elastic body, i. 340; shot wounds generally complicated by foreign bodies in their cavity, i. 340; prognosis, i. 340; indications of treatment, i. 340; circumstances under which the enlargement of the wound may be necessary, i. 340; Hennen on the treatment of wounds by a ball in the fleshy part of the arm, thigh, or buttock, i. 341; general and local treatment, i. 341; occurrence of suppuration, i. 341; of secondary hæmorrhage, i. 341; Guthrie, Samuel Cooper, and Dupuytren on secondary hæmorrhage, i. 341; local and general treatment during suppuration, i. 342; Hennen and Dr. Arthur on the use of the seton to bring away separated pieces of bone, i. 342; Staff-Surgeon Boggie's cases, i. 342; treatment of shot wound complicated with fracture, i. 342; Hennen on the occurrence of necrosis in gun-shot injuries of bones, i. 342; bleeding from the whole surface of the wound in long-continued suppuration, i. 343; the circumstances in gun-shot wounds requiring amputation on the spot, i. 343; Hennen on the nature of the injuries in gun-shot wounds requiring amputation, i. 344; amputation, under the circumstances mentioned, should be performed early, i. 344; Wiseman, Le Dran, and Ranby on immediate amputation, i. 345; Faure on the propriety of delaying the operation, i. 345; Bilguer's objections to amputation altogether, i. 345; Hunter's objections to primary amputation, i. 345; Hennen, Pitcairn, Gunning, and Guthrie on immediate amputation, i. 346; Guthrie's reasons for an early performance of the operation, i. 347; symptoms which may require the performance of amputation at a time more or less posterior to the date of the injury, i. 347; *poisoned wounds,* i. 348; definition, i. 348; dissection-wounds, i. 349; symptoms and treatment, i. 349; cause of the symptoms after injuries in dissection, i. 349; South objects to the application of caustic in dissection-wounds, i. 349, 350; J. Shaw on dissection-wounds and their treatment, i. 349; Basedow considers dissection-wounds agree with malignant pustule, i. 349; South and Lawrence on the absorption of poisonous matter in dissection-wounds, i. 349; details of Dr. Pett's case, i. 350; South on the most dangerous punctures, those received in cases of simple or puerperal peritonitis, i. 350; South on the consequences of dissection-wounds, i. 350; stings of bees, wasps, &c., i. 351; Dr. Gibson and Lawrence on the fatal effects of the stings of bees and wasps, i. 351; Dr. Moseley's case of scorpion-sting, i. 351; Allan, Curling, Kirby, and Spence on the effects of the scorpion-sting, i. 351; bites of the gnat, mosquito, harvest bug, bête-rouge, and American tick, i. 352; Dr. Moseley on the chigoe, i. 352; symptoms following the bite of a viper, i. 353; local and general treatment, i. 353; Pennock and Rodrigues on the effects of cupping-glasses in viper-bites, i. 353; Fontana on the effects of viper-bites, i. 353; Vincent's case, i. 354; South on viper-bites, and their treatment, i. 353; Dr. Mead on viper's fat a local remedy in viper's bite, i. 354; Celsus, Astley Cooper, and Home on the application of a ligature above the bite, i. 354; suction of venemous bites, i. 354; Celsus' observation on the innocuous qualities of the poison of serpents when introduced into the mouth, confirmed by Russell, i. 354; Dr. Mead's case of the bite of a rattlesnake, i. 354; Sir David Barry on the application of the cupping-glass over snake-bites, i. 355; Dr. Mead's experiments on viper-poison, i. 355; snake-bites and their treatment, i. 355; Dr. Barton on the symptoms produced by the bite of the rattlesnake, i. 356; Professor Owen's case of viper's bite, i. 356; Home's case of bite of the rattlesnake, i. 356; Dr. Russell on the symptoms produced by the bite of a cobra de capello, i. 357; Russell's cases of fatal snake-bite, i. 358; Barton on the treatment of rattlesnake-bites, i, 358; Russell on the treatment of snake-bites in India with the Tanjore pill, i. 359; Ireland on the use of arsenic in the bites of the great lance-headed viper of Martinique, i. 359; Russell on the physical qualities of snake-poison, i. 359; Barton on the employment of the ligature in snake-bites, i. 359; bite of a rabid beast, i. 359; bite of beasts much excited, or when disturbed during copulation, may produce canine madness, i. 360; cause of dog-madness, i. 360; spontaneous development of hydrophobia in man, i. 360; signs of incipient madness in the dog, i. 360; Hertwig on canine madness, i. 360; progress of the disease, i. 361; signs of dumb-madness in the dog, i. 361; Youatt on rabies in the dog, i. 361; Youatt on the peculiar bark of the mad dog, i. 362; Youatt on the saliva of the mad dog, i. 363; Youatt on the condition of the lumbar portion of the spinal cord in rabies and dumb-madness in the dog, i. 363; Youatt on a peculiar paralysis of the muscles of the tongue and jaws occasionally occurring in mad dogs, i. 363; Youatt on the insensibility to pain in mad dogs, i. 363; Youatt on the diagnosis between pain in the ear in canker and in hydrophobia in the dog, i. 363; Youatt on the period of incubation of rabies in the dog, i. 364; Hertwig's experiments shew that the saliva is the vehicle of the mad poison, i. 364; Trolliet considers the mucus from the inflamed mucous membrane of the bronchi the vehicle of the poison, i. 364; Hertwig's experiments also shew the contagion to be in the blood of the mad beast, i. 364; Youatt on the appearances on dissection in the dog, i. 364; Youatt's caution against suffering dogs to lick the face, or hands, or any other part of the body, i. 365; Lawrence's details of the Hon. Mrs. Duff's case, i. 366; Lawrence on the communication of hydrophobia from one human being to another, or from man to beasts, i. 366; Magendie and Breschet's experiment, i. 366; period of incubation of hydrophobia in man, i. 366; Galen, Mead, and Hale Thomson on the protracted period of incubation of hydrophobia, i. 366; Dr. Bardsley's case of the disease twelve years after the bite had been inflicted, i. 367; his opinion that the disease was not hydrophobia, i. 367; supports his view by the opinions of Darwin, Haygarth, and R. Pearson, i. 367; Elliotson on the period of incubation, i. 367; Dick on the nature of the disease in hydrophobia, i. 367; symptoms of incipient hydrophobia, i. 367; Urban's opinion that there is a circlet of small vesicles around the wound or scar, i. 368; general symptoms, i. 368; Elliotson on the symptoms of, i. 368; Elliotson on the diagnosis between true and spurious hydrophobia, and inflammation of the pharynx, i. 369; disposition of hydrophobic patients to bite doubted by South, i. 369; Powell and Magendie's cases, i. 369; Cline jun. on the disposition of hydrophobic animals to use their weapons of offence, i. 369; Elliotson on a general morbid irritability in hydrophobia, i. 369; Youatt on the peculiar delirium in, i. 369; Bardsley and Babington's cases, illustrative of this delirium, i. 369; Lawrence on the peculiar delirium of hydrophobia, i. 370; Youatt on the tenacity of the human saliva in, i. 370; Elliotson on the duration of the disease, i. 370; Mead on the increase of muscular strength in hydrophobia, i. 370; Elliotson on abortive hydrophobia, i. 370; Dr. Bardsley on the stages of hydrophobia, i. 370; Marcet, Babington, and Callisen on the premonitory pains of, i. 371; post-mortem appearances, i. 371; Locher on vesicles of the spleen in hydrophobia in dogs, i. 371: the post-mortem appearances in Elliotson's case, i. 371; proximate cause, i. 371; Harder on the action of the poison on the system, i. 372; Langenbeck on hydrophobia as caused by a qualitative alteration of the blood by the poison, i. 372; prognosis, i. 372; treatment of the bite, i. 372; Youatt's objections to excision of the bitten parts, i. 372; South on excision, i. 373; Cline's directions for the excision, i. 373; South on excision of the scar, i. 374; internal prophylactics of hydrophobia, i. 374; plan of treatment recommended by Wendl, i. 374; Brera and von Schallein's treatment, i. 374; Marochetti on the presence of pustules under the tongue after the bite of a mad animal, i. 375; Marochetti's plan of treatment, i. 375; Watson's objections to Marochetti's views, i. 376; general treatment, i. 376.

WRIGHT, Dr., on ligature of the external iliac, ii. 261; case in which he performed the operation of lithectasy, ii. 643.

WRIGHT on amputation just above the ancle, ii. 921.

Wrist, fracture of the bones of, i. 562; dislocations of, i. 792; exarticulation of the hand at, ii. 963; excision of, ii. 976.

Wry neck, ii. 152.

WUTZER on the use of the suture in vesico-vaginal fistula, i. 753; puncture of the bladder above the pubes after this operation, i. 756; after-treatment, i. 757; on congenital dislocation of the knee, i. 806; modification of Gerdy's operation for the radical cure of rupture, ii. 25.

YOUATT on rabies in the dog, i. 361; on the peculiar bark of the mad dog, i. 362; on the saliva of the mad dog, i. 363; on the condition of the lumbar portion of the spinal cord in rabies and dumb madness in the dog, i. 363; on a peculiar paralysis of the muscles of the tongue and jaws occasionally occurring in mad dogs, i. 363; on the insensibility to pain, i. 363; on the diagnosis between pain in the ear in canker and in hydrophobia in dogs, i. 363; on the period of incubation of rabies in the dog, i. 364; on the appearances on dissection, i. 364; caution against suffering dogs to lick the face or hands, or any other part of the body, i. 365; on the peculiar delirium in hydrophobia, i. 369; on the tenacity of the human saliva in hydrophobia, i. 370; objections to the excision of the bitten parts, i. 372.

YOUNG, Dr., on the genus carcinoma, ii. 716.

YOUNG on compression in scirrhus, ii. 770.

ZANG on laying open a cold abscess longitudinally, i. 90; on the more general application of the trephine, i. 413; on suture of urethral fistula, i. 741; on the treatment of recto-urethral and recto-vesical fistulæ, i. 748; on ligature of the common carotid, ii. 234; mode of amputating the thigh with the flap from the inner side, ii. 909.

ZEISS on the introduction of charpie under the edge of the nail, and on the use of foot-baths in treating ingrowing of the nail, i. 200; on the operation for removing the diseased nail, i. 200; case of ligature of the carotid, ii. 233.

ZELLER's operation for united fingers and toes, ii. 309.

ZEMBSCH's opinion on the lymph-swelling, i. 48.

ZIMMERMANN on the elimination of the molecular fibrin, i. 32.

ZINK on the situation and direction of scoliosis, ii. 161.

ZITTMANN's decoction in the treatment of syphilis, i. 667; formula for it, i. 667; mode of employing it, i. 667.

INTRODUCTION.

I.

DEFINITION OF SURGERY.—ITS RELATION TO THE HEALING ART IN GENERAL.—DIVISION OF SURGICAL DISEASES.

ALL diseases to which the animal organism is exposed, are the object of the science of healing, the purpose of which is their *prevention, cure, or alleviation.* The means we employ to these ends are either *dietetic* or *pharmaceutic*, or they consist in the *application of suitable mechanism,* which we call *surgical means,* and the doctrine of their proper employment, which is called *surgery.*

Every mechanical influence employed with skill upon the diseased organism is called a *surgical operation.* This influence consists either in a direct interference with the form and natural connexion of the part (*Bloody operations,* Akiurgie (*a*), Germ.); or only in a momentary or continued application of mechanism fitted to the surface of our bodies; to which belong *bandages* and *machines,* simple manipulations for restoring the natural position of parts, and the employment of suitable mechanism for repairing parts which have been destroyed (*Kosmetik* (*b*), Germ.)

There are diseases which specially require the employment of one or other class of the means just mentioned: the purpose, however, of the healing art is in most cases but imperfectly attained, if the medical man be not possessed of the requisite knowledge for deciding upon the necessary connexion of these means, so as properly to conduct their operation by a sufficient acquaintance with the laws of our organism, whence it necessarily follows that there cannot be established any true separation between the so-called *medical* and *surgical* treatment.

The employment of surgical means calls for peculiar dexterity and aptness which natural talents and disposition and long practice can alone confer. "*Esse autem chirurgus debet,*" says CELSUS (*c*), "*adolescens, aut certè adolescentiæ propior, manu strenuâ, stabili nec unquam intremiscente, eâque non minus sinistrâ quam dextrâ promptus, acie oculorum acri clarâque; animo intrepidus, immisericors, sic, ut sanari velit eum, quem accepit, non ut clamore ejus motus, vel magis, quam res desiderat, properet, vel minus, quam necesse est, secet; sed perinde faciat omnia, ac si nullus ex vagitibus alterius affectus oriretur.*" Only in reference therefore to the physical and psychical characters of the medical man, can there be any division in the practice of medicine and surgery: in their attainment they cannot be separated, and, by the union of medical and surgical study alone, can the foundation be destroyed upon which so much bungling, and so many practices unworthy of the spirit of high art, have hitherto been supported.

(*a*) Ἀκὴ, the edge of a knife; ἔργον, an operation.

(*b*) Κοσμέω, to set in order.

(*c*) De Medicinâ, præf. ad lib. vii.

The study and practice of Surgery are connected with great difficulty. The dexterity and exactitude with which surgical operations must be performed, can only be attained by long practice on the dead body, the opportunity for which is rare; and still rarer the perseverance necessary to overcome the various disagreeables therewith connected. How much does this practice on the dead body still leave imperfect when we have to meet operations on the living! In how many instances does the life of the patient depend momentarily on the hand of the operator; the restlessness of the patient, his cries, a peculiar sensation to which no practitioner is a stranger in operating on the living subject, and particularly in the beginning of his career, easily disturb his needful equanimity, render him anxious and incapable of perfecting his work with firmness and certainty. Therefore are we not surprised on reading the open confession of the great **Haller.** "*Etsi chirurgiæ cathedra per septemdecim annos mihi concredita fuit, etsi in cadaveribus difficillimas administrationes chirurgicas frequenter ostendi, non tamen unquam vivum hominem incidere sustinui, nimis ne nocerem veritus.*"

In the employment of surgical means the practitioner can only be guided by the most perfect anatomical knowledge. That knowledge of the structure of our body, with which the general practitioner is content, is insufficient for the operator. He must be most intimately acquainted by careful dissection with the position of every part, its relations to others, and the variations which in this respect may occur, so that this definite knowledge may direct him in every moment of an operation. Mere descriptive anatomy is not sufficient for the surgeon without that comparative anatomy which is directed to physiology, and which has in view the early developmental periods of the several organs, by which alone a true insight into the nature of so many diseases is possible.

All these difficulties connected with the acquirement and practice of Surgery, are sufficiently rewarded by the great superiority which, on the other hand, the practice of them offers. In most cases where surgical assistance is necessary, the possibility of preserving the patient depends upon it: we must, therefore, in desperate cases take bold measures, and the advance of Surgery within the last few years in this respect, has raised our astonishment at the heroism of art, as well as at the immeasurable resources of nature. In this point of view has **Marcus Aurelius Severinus** most correctly entitled his book on surgical diseases, *De Medicinâ Efficaci.*

The inadmissibility of dividing Medicine from Surgery is most palpable, when we endeavour to determine the object of the latter, and the diseases comprehended within its boundaries, as it never can have a perfectly determined limit in opposition to the other. All diseases which are cured by the application of mechanical means have been called surgical diseases, a definition at once too narrow and too comprehensive, as many so-called medical diseases are removed only by the application of surgical means, and many diseases are evidently within the jurisdiction of Surgery, which very often can be cured only by internal or external pharmaceutical means. The distinction between external and internal diseases, which has been established as the ground of division between Surgery and Medicine, is entirely without meaning.

Let us endeavour to find out some general characters of disease which to a certain extent might legally serve as the law for a nosological division, and to distinguish those diseases to which we would assign the name of surgical.

As the phenomena of life present to us by the relative predominance of *powers and organs*, a *dynamic*, *potential*, and *organic material phase*, on the intimate harmony of which health depends, so do we observe also in the diseased states of the organism, that sometimes the power, sometimes the organ, varies more from the natural type, whence arises the difference between *dynamic* and *organic diseases*. This distinction can, however, only indicate a relatively predominant suffering of one or other phase of life, since the organic body presents in itself an entire whole, of which the several parts and phenomena are in the closest mutual connexion with each other.

The organic diseases are especially those which originate in a destruction of the natural condition, form, and structure of organized tissues, and therefore may generally depend, 1. *on the disturbance of organic connexion*; 2. *on the unnatural union of parts*; 3. *on the presence of foreign bodies*; 4. *on the degeneration of organic parts, or on the production of new structures*; 5. *on the entire loss*; and, 6., *on the superfluity of organic parts*.

Organic diseases must be distinguished into such as have their seat in parts inaccessible to mechanical contrivances, and to our organs of touch, and whose cure therefore can only be attempted by dietetic and pharmaceutic remedies, or whose seat permits the employment of external means and regulated contrivances, and which in most cases can be brought to heal only by these contrivances, with the assistance of dietetic and pharmaceutical aids. *We may therefore distinguish as belonging to the province of Surgery all those organic diseases which have their seat in parts accessible to our organs of touch, or which allow of the employment of mechanical means for their cure.*

Although inflammation is excluded from this general definition, we must, however, still enumerate it generally, and particularly among the manifold origins of surgical diseases, when it attacks external parts. Inflammation in its course and results produces for the most part organic changes, and requires, when attacking external parts, almost always the employment of the so-called surgical means: further, among the surgical diseases soon to be more particularly described, there is not one of which the cause is not inflammation, which in its course does not produce inflammation, or the cure of which is not to a certain extent singly and alone possible by inflammation.

After these observations, we therefore prefer the following division for the setting forth of surgical diseases, which, if it be open to many objections, is, however, an arrangement of diseases according to their internal and actual agreement:—

I. Division.—*Of inflammation.*

1. *Of inflammation in general.*
2. *Of some peculiar kinds of inflammation.*
    a. Of erysipelas; *b.* Of burns; *c.* Of frost-bite; *d.* Of boils; *e.* Of carbuncle.
3. *Of inflammation in some special organs.*
    a. Of inflammation of the tonsils; *b.* Of the parotid gland; *c.* Of

the breasts; *d.* Of the urethra; *e.* Of the testicle; *f.* Of the muscles of the loins; *g.* Of the nail-joints; *h.* Of the joints, viz.
a. of the synovial membrane; b. of the cartilages; c. of the joint-ends of the bones, viz., *aa.* in the hip-joint; *bb.* in the shoulder-joint; *cc.* in the knee-joint; and so on.

II. DIVISION.—*Diseases which consist in a disturbance of physical connexion.*

I. *Fresh solutions of continuity.*
  A. Wounds; B. Fractures.
II. *Old solutions,*
  A. Which do not suppurate, viz.
    a. False joints; *b.* Hare-lip; *c.* Cleft in the soft palate; *d.* Old rupture of the female perineum.
  B. Which do suppurate, viz.
i. *Ulcers.*
  1. In general.
  2. In particular.
    a. Atonic; *b.* Scorbutic; *c.* Scrofulous; *d.* Gouty; *e.* Impetiginous; *f.* Venereal; *g.* Bony ulcers or caries.
ii. *Fistulas.*
  a. Salivary fistula; *b.* Biliary fistula; *c.* Fæcal fistula and artificial anus; *d.* Anal fistula; *e.* Urinary fistula.
III. *Solutions of continuity by changed position of parts.*
  1. Dislocations; 2. Ruptures; 3. Prolapses; 4. Distortions.
IV. *Solutions of continuity by unnatural distension.*
  1. In the arteries, aneurisms; 2. In the veins, varices; 3. In the capillary-vascular system, telcangiectasis.

III. DIVISION.—*Diseases dependent on the unnatural adhesion of parts.*

1. Anchylosis of the joint-ends of bones; 2. Growing together and narrowing of the aperture of the nostrils; 3. Unnatural adhesion of the tongue; 4. Adhesion of the gums to the cheeks; 5. Narrowing of the œsophagus; 6. Closing and narrowing of the rectum; 7. Growing together and narrowing of the prepuce; 8. Narrowing and closing of the urethra; 9. Closing and narrowing of the vagina and of the mouth of the womb.

IV. DIVISION.—*Foreign bodies.*

1. *Foreign bodies introduced externally into our organism.*
  a. into the nose; *b.* into the mouth; *c.* into the gullet and intestinal canal; *d.* into the wind-pipe.
2. *Foreign bodies formed in our organism by the retention of natural products.*
  A. Retentions in their proper cavities and receptacles.
    a. Ranula; *b.* Retention of urine; *c.* Retention of the fœtus in the womb or in the cavity of the belly (Cæsarean operation, section of the pubic symphysis, section of the belly).
  B. Extravasation external to the proper cavities or receptacles.
    a. Blood swellings on the heads of new-born children; *b.* Hæmatocele; *c.* Collections of blood in joints.

3. *Foreign bodies resulting from the accumulation of unnatural secreted fluids.*
   a. Lymphatic swellings; *b.* Dropsy of joints; *c.* Dropsy of the bursæ mucosæ; *d.* Water in the head, spina bifida; *e.* Water in the chest and empyema; *f.* Dropsy of the pericardium; *g.* Dropsy of the belly; *h.* Dropsy of the ovary; *i.* Hydrocele.
4. *Foreign bodies produced from the concretion of secreted fluids.*

V. Division.—*Diseases which consist in the degeneration of organic parts, or in the production of new structures.*

1. Enlargement of the tongue; 2. Bronchocele; 3. Enlarged clitoris; 4. Warts; 5. Bunions; 6. Horny growths; 7. Bony growths; 8. Fungus of the dura mater; 9. Fatty swellings; 10. Encysted swellings; 11. Cartilaginous bodies in joints; 12. Sarcoma; 13. Medullary fungus; 14. Polyps; 15. Cancer.

VI. Division.—*Loss of organic parts.*

1. *Organic replacement of already lost parts*, especially of the face, according to the Tagliacozian and Indian methods.
2. *Mechanical replacement:* Application of artificial limbs, and so on.

VII. Division.—*Superfluity of organic parts.*

VIII. Division.—*Display of the elementary management of surgical operations.*

General surgical operations: Bleeding, cupping, application of issues, introduction of setons, amputations, resections, and so on.

II.

HISTORICAL SKETCH OF SURGERY.

First period...	to the time of Hippocrates.
Second period.	from Hippocrates to Galen.
Third period..	from Galen to the fifteenth century.
Fourth period.	the sixteenth century to the middle of the seventeenth.
Fifth period..	the second half of the seventeenth century to the present time.

The origin of Surgery is founded on the relation of man to external nature, and on his disposition to alleviate the sufferings of his fellow men. In ancient Egypt and Greece the history of Surgery lies in darkness, and it begins in a special sense with Hippocrates, who collected the previously scattered facts, arranged them, and published rational views, drawn from his own experience. It appears from his writings—*καθ' ἰητρεῖον*—*περὶ αγμῶν*—*περὶ τῶν εν κεφαλῆ τρωματων*—*περὶ ἄρθρων*—*περὶ ἑλκῶν*—*περὶ ϛυρεγγῶν*—that he was acquainted with a copious apparatus of instruments and bandages, and several operations exhibit an actual technical tendency. In different parts of his Aphorisms he treats of surgical subjects.

In the Alexandrian school Surgery became more prominent, as it rested on its proper basis, anatomy. Erisistratus and Herophilus made the first examinations of human bodies. We know of their followers and their performances only from subsequent writers

Aurelius Cornelius Celsus is the sole writer after Hippocrates (a period of 400 years intervening between them.) Although Celsus lived at Rome, his writings for the most part belong to the Greeks. In his seventh book he specially treats of surgical operations. After Celsus deserve to be mentioned Soranus, Archigenes, and Rufus.

Claudius Galenus, born A.D. 131, lived at Rome under the Emperor Marcus Aurelius: such of his writings as treat of Surgery are, for the most part, commentaries on those of Hippocrates—as his *'Υπόμνηματα τρία εἰς τὸ βιβλιον 'Ιπποκράτους κατ' ἰητρεῖον—αὐτα περὶ ἀγμῶν—ὑπόμν. τέσσαρα ἄρθρων—ὑπόμν. εἰς τοὺς ἀφορισμους.* Besides which also his own Treatises, *περὶ τῶν ἐπιδεσμων—περὶ βδέλλων, ἀντιϛπάσεως; σικὺας, και ἐγχὰράξεως καὶ καταϛκασμου—περὶ τῶν παρὰ φὺσιν ὂγκων*—and *θεράπευτικης μέθοδου βιβλίον·* After Galenus there is a complete stand-still, and up to the sixteenth century there are but few writers: Oribasius, Aetius, Alexander of Tralles, and Paulus of Ægina.

With the fall of the Roman Empire and the invasion of the Arabs, came a period of darkness and barbarism. We find Surgery, at this time, in the hands of the Arabian physicians, characterized by the neglect of anatomy, with a copious instrumental apparatus, fear of the knife, and frequent employment of the cautery iron. The most remarkable men of this period were Ebn Sina and Abulcasem.

The practice of Medicine and Surgery was, during this time, in Christian Europe, in the hands of the clergy, and sank down to such imperfection, that the knowledge of operations, possessed by the Greeks, was no longer to be met with. In the twelfth and thirteenth centuries, indeed, art and science raised themselves by the foundation of literary institutions; but, as their most special object was the education of ecclesiastics, there was little gain to Surgery. The latter was, at a subsequent period, completely separated by two decrees of the Pope from Medicine, and the priests were forbidden *every bloody* operation on pain of excommunication. At this time arose the barbery system, under which the barbers of the priests were employed by them for the performance of the lesser operations of Surgery. In Italy alone was there yet any striving towards improvement, and Surgery still partially remained in the hands of better practitioners.

In the year 1311 Pitard, of Paris, collected the Surgeons into a company, which formed itself into a college; but, owing to the long-continued disputes with the medical faculty, and without advance in anatomy, Surgery remained in its restricted condition.

[During a large portion of the fourteenth century flourished in England John of Arden, who was born in 1307, and certainly lived till after 1377, as, in a manuscript (MSS. Sloane, No. 75, in Brit. Mus.) which, he says, "propriâ manu meâ exaram," he declares himself 70 years old, "regni regis Richardi 2^{di} primo." From examination of his works, written in Latin, several manuscripts of which, together with many English translations in MSS. of the whole or part of his works, are in the library of the British Museum and in the Bodleian Library at Oxford, it is probable that he did not know much about anatomy, though perhaps he was not more ignorant than his contemporaries. But he was certainly an attentive observer and a careful recorder of what he saw. He wrote specially upon anal fistula, which was translated by **Read** in 1588, and also a Practice of Surgery, in which, among other things, he speaks of sores on the penis, also of gonorrhœa, and describes what is to be done when a stone gets into the urethra. From the number of manuscripts and translations it is quite evident he was long held in great repute by his countrymen, and his works are quite equal and much more original than those of surgical writers of the early part of the sixteenth century. It is much to be regretted that the several manuscripts have not hitherto been collated and published, as they present an excellent view of the state of Surgery in England at this period.—J. F. S.]

With **Guido de Chauliaco** (who lived at Avignon) first commenced a period of independent exertion and reference of Surgery to the basis of anatomy.

[In 1542 the Surgeons, who had previously existed in London as one if not two distinct bodies or brotherhoods, were united without any very good reason beyond, perhaps, **Henry the Eighth**'s pleasure, by act of Parliament, to the Barbers' Company of London; but they were only paired, not matched, as it appears that their Court of Assistants was equally divided between the two professions, the Barbers having their side, the Surgeons theirs, but neither interfering with the other's department. This Act of Parliament encouraged dissection by directing that "the masters or governors of the said mystery" should have, "at their free liberty and pleasure," the bodies of four felons, "to make incision of the same * * * for their further and better knowledge, instruction, insight, learning, and experience in the said science or faculty of Surgery." From the destruction of the books it cannot be ascertained whether dissection was forthwith pursued; but, in 1566, public demonstrations and dissections were enacted by the Company of Barbers and Surgeons to be held in their hall at stated periods, and conducted by two masters and two stewards of the "anathomies." There was also a readership of anatomy at the hall, which was long held by physicians appointed by the Court of Assistants, but when instituted is doubtful. **Wadd** says that Dr. **William Cunningham** lectured there in 1563; but the first appointment I can find is that of Dr. **Paddy**, who was appointed reader of the anatomy lectures on the 11th July, 1596.

The study of anatomy does not seem to have been so little thought of at this time as generally believed, in proof of which it may be mentioned that Sir **Edward Arris**, an alderman of London, who was also warden in 1642, and master of the Company of Barbers and Surgeons in 1651, founded on the 27th October, 1645, six anatomical lectures, to be publicly read every year between Michaelmas and Christmas, and endowed them with 300*l.*, on condition that the Company should pay for the lectures 20*l.* a-year: subsequently he exchanged this sum for an annuity of 30*l.* charged on his estates, and at a later period redeemed this charge by paying 510*l.* to the Company, which was by them paid over at the dissolution to the Surgeons' Company, and, when the latter merged into the College of Surgeons, the same was handed over to them. **Arris**'s good example was followed by Mr. **John Gale**, who, on the 30th June, 1698, founded one anatomy lecture every year, to be called **Gale**'s Anatomy, and endowed it with a rent-charge of 16*l.* a-year out of certain landed property, which was subsequently sold for 432*l.* sterling, and the interest thereon now produces rather more than 20*l.* The two endowments are now consolidated, and the lectures on human anatomy and Surgery are called Arris's and Gale's Lectures.—J. F. S.]

In this way, assisted by the advance of anatomy, was Surgery raised, by Paré, Franco, Fabricius Hildanus, Fabricius ab Aquapendente, Severinus, and Wiesemann, in the sixteenth century, to a high station.

In the second half of the sixteenth century actually commences the brilliant period of Surgery. Numerous wars and the establishment of public hospitals presented a rich field for observation, and the foundation of the Academy of Surgery at Paris collected scattered powers and aroused a general emulation. In France shone out Dionis, J. L. Petit, Mareschal, Quesnay, Morand (*a*), Louis, Ledran, Garengeot, Lafaye, Lecat, Lamotte, Ravaton, David, Pouteau, Levret, Sabatier, Desault; in England, Wiseman, Cheselden (*b*), Douglas, the two Monros, Sharp, Cowper, Alanson, Pott, Hawkins, Smellie, and the two Hunters; in Holland, Albin, Deventer, Camper; in Italy, Mollinelli, Bertrandi, Moscati, Scarpa; in Germany, Heister, Plattner, Bilguer, Brambilla, Theden, Richter, C. Siebold, and Mursinna.

By this general cultivation has Surgery been brought up in modern times to an elevation which cannot be displayed generally but only in the history of the several operations. Boldness grounded on the progress of anatomy and physiology, simplicity in the methods of treatment, and scientific culture, distinguish it.

The equal participation of all civilized nations in these efforts keeps up amongst them a contest for intellectual superiority in the ranks of improvement, while it makes any decisive award impossible.

(*a*) He was Secretary to the Academy of Surgery, and, on the opening of the schools in 1743, delivered a most admirable address, "Discours dans lequel on prouve qu'il est nécessaire au Chirurgien d'être lettré," in which he shows the necessity of a literary education for a Surgeon, and mentions incidentally that the royal declaration founding the Academy, required "that the Surgeons of Paris should be Masters of Arts before admission into the community, and that they should then pursue Surgery without mixing any mechanics," "loi précieuse," says he, "qui, faisant une des époques les plus mémorables pour l'illustration de notre art, doit immortaliser celui (De la Peyronie) qui la sollicitée et dont les titres éminens sont soutenus par un mérite supérieur." *Opuscules de Chirurgie*, p. 118. Paris, 1768. 4to.

(*b*) He established the first School of Anatomy in London, independent of the Barbers' and Surgeons' Company, at St. Thomas's Hospital about the year 1714.

1. INFLAMMATION (*Inflammatio, Phlogosis,* Lat.; *Entzündung,* Germ.; *Inflammation,* Fr.) is that condition of an organized part in which the vital process and plasticity of the blood are unnaturally raised, and which is manifested by pain, redness, increased temperature, and swelling.

The elevation of the vital process must be of a certain duration and intensity, that is it must be actually diseased, when we apply to it the name *Inflammation.* Thereby, alone is inflammation distinguished from [the temporary condition of *active congestion* and increased *turgor vitalis.* The proximate cause of these phenomena is indeed the same as in inflammation, and may run into it. The same applies to the so-called inflammatory irritation.

[The term "inflammation" has been objected to by ANDRAL (*a*), one of the most able French writers on pathology. He says:—"Created in the infancy of science, this expression, (inflammation,) completely metaphorical, was destined to represent a morbid condition, in which parts seemed to burn, to inflame, as if they had been subjected to the action of fire. Received into the language, without any precise idea having ever been attached to it, under the triple relation of symptoms which announce it, of lesions which characterize it, and of its actual nature, the expression "inflammation" has become so vague, and its interpretation so arbitrary, that it has really lost all value: it is like a piece of old money without the impress, which must be put out of circulation, as it causes only error and confusion. Inflammation can only be considered as the expression of a complex phenomenon, comprehending many other phenomena, the dependence of which is neither necessary nor constant." (vol. i. p. 9.) He has, therefore, chosen to set aside the term "inflammation" as generally characterizing the phenomena we are about to consider, and has employed that of "hyperæmy," restricting it, however, only to that condition of the vessels in which they are loaded or congested with blood, from whatever cause, healthy or unhealthy, such condition may arise. JOHN HUNTER (*b*) seems to have anticipated these objections; for, he observes:—"The term or idea of inflammation may be too general, yet it is probable that it may form a genus, in which there is a number of species, or it may be more confined in its classification, and be reckoned a species containing several varieties. These are, however, so connected among themselves, that we cannot justly understand any one of the species or varieties without forming some idea of the whole, by which means, when treating of any one, we can better contrast it with the others, which gives us a clearer idea, both of the one we are treating of, and of the whole." (p. 265.) The difficulty, however, is to distinguish the onset of the diseased action, inflammation, from the natural one, congestion or turgescence. Their close resemblance was first pointed out by HUNTER, who observes:—"The very first act of the vessels when the stimulus which excites inflammation is applied, is, I believe, exactly similar to a blush. It is, I believe, simply an increase or distension beyond their natural (ordinary?) size. This effect we see takes place on many occasions: gentle friction on the skin produces it; gently stimulating medicines have the same effect; a warm glow is the consequence similar to that of the cheek in a blush: and, if either of these be increased or continued, real inflammation will be the consequence." (p. 279.) So ANDRAL:—"Will anatomy establish any line of demarcation between physiological (healthy) and pathological congestion? No more than the latter can always be strictly separated from the complex phenomenon called "inflammation." Thus, under the influence of violent emotion, vessels appear on the conjunctive coat of the eye, and the lids become red. The same effect follows a grain of sand falling on the front of the eye; insensibly does the congestion increase from that almost normal condition in which vessels appear on the conjunctive coat to that when the mucous membrane of the eye, becoming uniformly red and considerably swelled, presents that variety of opthalmy known as *chemosis.*" (vol. i. p. 13.) The same language is held by MULLER (*c*):—"Inflammation begins, indeed, with phenomena which are similar to turgescence. The organs attract more blood than usual, in consequence of the altered affinity between the blood and the tissue, and obstructs its efflux; but we must be very cautious in calling increased vital action that important change caused by inflammatory irritation which produces functional disturbance, and has consequent to it an effort of nature to compensate an injury which has interfered with the action of the organ. Had the vital action been increased, so would not the morbid processes of inflammation have occurred." (vol. i. p. 218.) HUNTER also observes:—"Though pure inflammation is rather an effort of nature than a disease, yet it always implies disease or disturbance, inas-

---

(*a*) Précis d'Anatomie Pathologique. (*b*) On the Blood, Inflammation, &c.
(*c*) Handbuch der Physiologie des Menschen.

much as there must be a previous morbid or disturbed state to make such effort necessary." (p. 260.) Again:—" Inflammation is to be considered only as a disturbed state of parts which require a new but salutary mode of action to restore them to that state wherein a natural mode of action alone is necessary: from such a view of the subject, therefore, inflammation in itself is not to be considered as a disease, but as a salutary operation, consequent either to some violence or some disease." (p. 249.) " Inflammation is not only occasionally the cause of diseases, but it is often a mode of cure, since it frequently produces a resolution of indurated parts, by changing the diseased action into a salutary one, if capable of resolution." (p. 250.) " Inflammation may first be divided into two kinds as first principles, viz., the healthy and the unhealthy. The healthy probably consists only of one kind, not being divisible but into its different stages, and is that which will always attend a healthy constitution or part, is rather to be considered as a restorative action than a diseased one, and would rather appear to be an effect of a stimulus than an irritation. The unhealthy admits of vast variety, (diseases being almost numberless,) and is that which always attends an unhealthy constitution or part, but principally according to the constitution: however, many parts naturally have a tendency to run into inflammations of particular kinds.* * The simple act of inflammation cannot be called specific, for it is an uniform or simple action in itself; but it may have peculiarities or specific actions superadded. Inflammation is either single or compound: it may be called single when it has only one mode of action in the part inflamed, as in its first stages; compound, when attended with another mode of action, or when it produces other effects." (p. 251.)]

2. All organs of the body may become inflamed except the cuticle, hair, and nails. The disposition to become inflamed depends on the number of nerves and capillary vessels in a part. The actual seat of inflammation is always the capillary-vascular system, and the ganglionic-nervous system, accompanying the most delicate branches of the vessels, which specially presides over vegetation in the organism.

[" Inflammation," says Hunter, " may arise from very different causes, and often without any apparent cause, and its operations are far more extensive than simply the act of producing union in parts divided by violence." (p. 248.) " Susceptibility for inflammation may be said to have two causes—the one original, the other acquired. The original constitutes a part of the animal economy, and is probably inexplicable. Of the acquired, it is probable that climate and modes of life may tend considerably either to diminish or increase the susceptibility for inflammation. The influence, however, of climate may not be so great as it commonly appears to be; for it is generally accompanied by modes of life that are not suited to others." (p. 226.) " Inflammation, when the constitution is strong, will be commonly the most manageable, for strength lessens irritability; but in every kind of constitution inflammation will be the most manageable where the power and the action are pretty well proportioned; but, as every part of the body has not equal strength, these proportions cannot be the same in every part of the same constitution. According to this idea of strength, the following parts—viz., muscles, cellular membrane, and skin,—and more so, in proportion as they are nearer to the source of the circulation—will be most manageable in inflammation and its consequences, because they are stronger in their powers of action than the other parts of the body. The other parts, as bone, tendon, ligament, &c., fall into an inflammation, which is less in the power of art to manage, because, though the constitution is good, yet they have less powers within themselves, and therefore are attended with the feeling of their own weakness; and I believe they affect the constitution more readily than the former, because the constitution is more affected by local disease, when the parts have less power within themselves of doing well; and the effects, if bad on the constitution, reflect a backwardness on the little powers they have. * * * The inflammation, if in vital parts, will be still less manageable; for, although the parts themselves may have pretty strong powers, yet the constitution and the natural operations of universal health become so much affected, that no salutary effect can so readily take place, and therefore the disease becomes less manageable. * * * In weak constitutions, although the inflammation be in parts which admit of the most salutary operations, in the time of the disease, and in situations the most favourable to restoration after disease, yet the operations of inflammation are proportionably more backward as to their salutary effects in such constitutions, and more or less, according to the nature of the parts affected." (pp. 228, 9.)]

3. Inflammation always commences with a more or less intense pain; the sensibility of the part is increased, redness soon follows, and blood appears in vessels where previously it had not been observed; the temperature of the part is raised, its functions disturbed, secretion suppressed, (at least at first,) or changed, perspiration diminished, and the part swelled. These appearances are developed, in different proportions, to a higher degree, in which fever (*Febris inflammatoria secunda*) usually becomes connected with them.

[I apprehend it would be more correct to say that "inflammation, from its very commencement, is always accompanied with a more or less intense pain," than to say, with our author, it "always commences with a more or less intense pain;" inasmuch as, though that by which the patient's attention is first excited, yet it is only an indication of a disturbance set up in the economy, and which, as it becomes greater, renders itself apparent to the eye, most commonly by redness.—J. F. S.

Dr. ALISON (*a*) observes:—"In order to give the requisite precision to the general notion of inflammation as a local change of the condition of any part of the body, it seems only necessary to include in it, besides the pain, swelling, heat, and redness, the tendency always observed, even when the changes in question are of short duration, to effusion from the blood-vessels of some new products; speedily assuming in most instances the form either of coagulable lymph or of purulent matter." (vol. i. p. 53.)]

4. The pain depends on the increased activity of the nerves (1), and this again produces the succeeding increased influx of the blood, and the vital expansion of the vessels (2); afterwards the pain is increased by the decided expansion and tension which the part suffers. It differs according to the degree of inflammation and the sensibility of the affected part: often it consists only in the sensation of prickling, itching, tickling, and a troublesome stretching; often is it stabbing, tearing, burning, and, in structures largely supplied with nerves, it attains a most vehement degree (3).

The redness, heat, and swelling, depend on the increased action of the nerves and capillary vessels, and is in immediate relation with the richness of their ramifications. Hence the various degrees of redness, heat, and swelling, according to the degree of inflammation and the organs therewith affected. At the onset of the inflammation the swelling always depends on an increase of blood. The reddening of the blood (4) and evolution of warmth are attributes of the living process: they must, therefore, be also increased by its greater activity. According, however, to experiments with the thermometer, the warmth in inflamed parts is not so considerable as to our touch it seems to be (5). Where the most delicate branches of the capillary-vascular system anastomose to form the transition into the veins, several capillary vessels always open together into one single vein. By this disposition of the capillary-vascular system there is already in the healthy state a slower motion of the blood, which is in close relation to the functions of the capillary-vascular system. If, then, in inflammation there be an additional influx of blood, there must arise with the *increased activity* of the capillary-vascular system and vital expansion (6) an accumulation of it, (the blood,) as the veins are not in a condition to take up and carry away with equal readiness the blood which is brought to them in excess. The capillary vessels become therefore expanded, as if filled by artificial injection, and even distinct in those parts where we assume that in the natural state vessels carrying only the uncoloured part of the blood exist: in the subsequent course of the inflammation new vascular branches are formed. The cellular tissue is the most especial seat of the development of vessels. These occurrences are the cause why

(*a*) Library of Medicine.

the inflammation, which at first was to be considered merely as a dynamic disease, brings about distinct changes in the structure of organs. The increased activity of the nerves and capillary-vascular system produces a more copious infiltration into the cellular tissue than in the natural state; a part of the serum—in some cases even of the red part of the blood—penetrates through the expanded walls of the vessels, and empties itself into the cellular tissue. The walls of the cells are, therefore, in this case, found thickened, filled with a serous, albuminous, often bloody fluid, in which frequently albuminous flakes float or are connected with the walls of the cells. The changed condition and increased plasticity of the blood is shown by the *crusta inflammatoria*, which consists of the fibrin of the blood.

According to the different degree of irritation, and the consequent reaction of the nervous system, so long as, excepting the pain, no other appearance of inflammation exists, (which condition many consider as the forerunner of inflammation,) there is produced a spasmodic contraction with accelerated motion of the blood in the small vessels, upon which first follow their vital expansion, the greater influx of blood, and the other phenomena of increased living actions (7). A comparison may therefore be instituted between these local appearances and those coming in with inflammatory fever. As we have there contractions of the vessels and obstruction of the circulation, so we have here chilliness, contraction of the skin, small pulse, which are followed by the phenomena of vital expansion of the vascular system, increased warmth, and so on. In the commencement there is in a manner present an inflammatory spasm—the vascular system is entirely controlled by the nervous system. With the increased influx of the blood, and its accumulation in the capillary vessels, is the previously quickened motion of the blood corpuscles retarded, the capillary vessels, by the consequent exudation of the serum, become completely filled with blood-corpuscles, and an actual stagnation, an inflammatory stasis ensues, but which is not to be considered as a passive over-filling.

[(1) But what causes this increased action of the nerves? The squeezing and stretching of the minute nerves of the part, by the increased size of the capillary vessels, resulting from the obstruction of the current of blood through them, which occurs at the very onset, and which, indeed, is, as will be presently shown, the first step of the inflammatory process. Travers (*a*) considers "the pain of inflammation directly or indirectly connected with the state of the blood-vessels," and it is, "probably, the nerves of the blood-vessels that are first excited in the pain of inflammation." (pp. 46, 7.) This opinion is corroborated by referring to John Hunter's observations on the passage of the adhesive to the suppurative inflammation, in which he says, "The pain is increased at the time of the dilating of the arteries, which gives the sensation called throbbing, in which every one can count his own pulse, from paying attention merely to the inflamed part; and perhaps this last symptom is one of the best characteristics of this species of inflammation." (p. 378.) And in a previous passage he had observed:—"Whether this pain arises from the distension of the artery by the force of the heart, or whether it arises from the action of distension from the force of the artery itself, is not easily determined." (p. 287.) The throbbing, however, is not entirely confined to suppurative, but also accompanies acute, inflammation; and Travers has well observed:—"Throbbing, lancinating or pulsatile pain,—*i. e.* pain accompanied with a sense of motion of the fluids in the part,—is the most characteristic distinction of acute inflammation; and an obtuse, aching, or heavy pain belongs to a congested state of the local circulation." And he also points out that "the description of pain unattended with inflammation, differs from the pain of inflammation, although the former is subject also to varieties in kind, duration and intensity;" observing that "Neuralgia is generally attended more or less with muscular cramp or spasm, and such pain is either intermitting or periodical;" and that such medicaments "as relieve pain in the absence of inflammation have little or no beneficial effect on the pain of inflammation. Blood-letting aggravates neuralgia and relieves inflammatory pain. Steel and arsenic aggravate inflammatory pain, and cure neuralgia." (pp. 45, 6.)

(2) According to his neuropathological theory, Henle (*b*) asserts, that "it is through the nervous system that the exciting cause of inflammation operates, by suspending the

---

(*a*) Physiology of Inflammation.

(*b*) I have made use of the Digest of this Author's Pathologische Untersuchungen, 1840, and of his Bericht über die Arbeiten im Gebiet der rationellen Pathologie seit Anfang des Jahres, 1839; in Wharton Jones's excellent Report on the Theory of Inflammation, in Forbes's Brit. and For. Med. Review, vol. xvii., 1844.—(J. F. S.)

nervous influence from the small vessels, and consequently determining relaxation of their walls with dilatation of their calibre." (p. 578.) The mode of action of the exciting cause he describes as follows:—"The exciting cause, of what nature soever it may be, whether external or internal, acts primarily on sensitive nerves, exalting their activity. The motor nerves of the vessels which have sympathetical relations with the excited sensitive nerves, are secondarily affected. But this affection of the motor nerves of the vessels, which supervenes by reflex action on the excitement of the sensitive nerves, is not a corresponding state of excitement, but an opposite one of depression, of suspension of action, of paralysis. This form of sympathy, on which the state of excitement of one nerve determines depression of another, **Henle** calls *antagonism;* when to that in which a state of activity of one nerve is called forth by a corresponding state of another, he applies the term *sympathy* in a more restricted sense than generally employed: the latter form is more common in the domain of the cerebrospinal system; the former in that of the ganglionic system, the source of the nerves of the vessels. Sometimes, however, sympathy is exemplified in the vessels by constriction supervening on irritation and preceding dilatation; but, in most cases, relaxation and dilatation of the vessels from suspension of nervous influence, are the primary effect of the irritation, no matter whether that irritation have been violent or moderate. Hence **Henle** contends that the relaxation of the vessels, on which their dilatation depends, cannot be a mere consequence of exhaustion of the vessels from previous action, as suggested by **Alison** and **Billing**, but can only be antagonistic." (p. 582.)

As to the cause of inflammation, **Hunter** observes:—"I will venture to say, that any cause which can obstruct the motion of the blood for a given time, will become the cause of inflammation; for, either the cause of the obstruction itself, or the blood being retained in the smaller vessels for a certain time, will either irritate or unite the parts, or, where it irritates, will throw the vessels into such actions as naturally arise out of an extraneous irritating cause, but not an increased motion of the blood behind, to drive on the obstructed blood through these vessels, as has been supposed." (p. 259.) The truth of these views is fully borne out by the observations of more recent inquiries, some of which will be presently detailed.

(3) In reference to the pain in inflammation, **Hunter** also notices that, as "Many parts of the body in a natural state give peculiar sensations when impressed: so when they are injured they give likewise pain peculiar to themselves;" of which the pain caused by squeezing or inflammation of the testicle is a good example. "And I may also observe," he says, "that the same mode of impression shall give a peculiar sensation to one part, while it shall give pain to another: thus, what will produce sickness in the stomach, will produce pain in the colon." (pp. 288, 9.)

Travers makes a remark shewing that pain is not necessarily an attendant on inflammation, which is well worth remembrance, and with which few careful observers will not accord. "We are told," says he, "there can be no inflammation where there is no pain. I reply, that there are many, and destructive too; a joint, an eye, nay, the lungs may be destroyed by inflammation without pain; he is a speculative, not a practical, pathologist who does not know this. It would be easy to superinduce pain in either of these cases; but let there be no interference, and the work of destruction in numberless cases is as silent as it is sure." (p. 29.)

(4) Touching the redness, **Hunter** observes:—"It is of various hues, according to the nature of the inflammation: if healthy, it is a pale red; if less healthy, the colour will be darker, more of a purple, and so on, till it shall be a bluish purple; * * * it is gradually lost in the surrounding part if the inflammation is of the healthy kind; but, in many others it has a determined edge, as in the true erysipelatous, and in some specific diseases, as in the small-pox." * * * "This increase of red appears to arise from two causes: the first is a dilatation of the vessels, whereby a greater quantity of blood is allowed to pass into those vessels which only admitted serum or lymph before; the second is owing probably to new vessels being set up in the extravasated uniting coagluating lymph." (pp. 283, 4.)

Travers thinks that the intensity of the redness depends "on the degree of fulness (of the vessels) compatible with motion; for, although the oxygen of the atmosphere will redden the blood in the congested vessels of the surface, while circulation, however imperfect, continues, from the commencement of the state of absolute stagnation, the colour gradually undergoes a change from pink to purple. In some modes of inflammation this shade of colour prevails even from the beginning, and soon turns to livid. * * * These varieties are due to the state of the general circulation, which gives its character to the inflammation, and an attending change in the constitution of the blood." (p. 50.)

(5) John Hunter observes on this point:—"From all the observations and experiments I have made, I do not find that a local inflammation can increase the local heat above the natural heat of the animal." The experiments he made were, 1. in the inflamed cavities of hydroceles, in which the thermometer stood at 98¾° F., an increase ended of 6¾° on the natural heat ascertained prior to the inflammation; but, as Hunter states, "not equal to that of the blood probably at the source of circulation in the same man:" 2. in a wound of a dog's chest, in which before and after inflammation the heat was 101°: 3. in a wound in the gluteal muscles of an ass 100° before, and varying from 99° to 101½° after inflammation: 4. in the vagina of an ass from 99½°, as before the inflammation to 100½°. In other experiments on mucous surfaces the heat was sometimes the same as before the inflammation, and sometimes increased 1° or 2°." (p. 293 to 300.) "But," as says Travers, "the nerves measure the sensation rather than the degree of heat, and this is a widely different scale from those of Fahrenheit or Réaumur, * * * this determination of blood to the capillaries in blushing is accompanied with a distinct though transient sensation of burning heat to the individual, yet not such as could be ascertained by the most delicate thermometer. It is most probably to be referred to the extraordinary inlet of arterial blood into the capillaries: its longer detention by the congestion proper to inflammation, and the consequent increase and vigour of the neighbouring circulation would give permanency to the sensation, and render the actual increase of temperature appreciable." (pp. 48, 9.)

(6) In reference to the enlargement of the vessels of an inflamed part, and its visibly-increased vascularity, Hunter observes, that, "instead of an *increased attraction*, there was rather what would appear an *increased relaxation*, of their muscular powers, being, as we might suppose, left to the elasticity entirely. This would be reducing them to a state of paralysis simply: but the power of muscular contraction would seem to give way to inflammation; for they certainly dilate more in inflammation than the elastic power would allow: and it must also be supposed that the elastic power of the artery must be dilated in the same proportion." And he comes to the conclusion, "When we consider the whole of this as a necessary operation of nature, we must suppose it something more than, *simply, a common relaxation*: we must suppose it an action in the parts *to produce increase of size*, to answer particular purposes; and this I should call the *action of dilatation*." (p. 282.)

(7) This is pretty nearly the opinion of Dr. Cullen, who taught that spasm of the extreme arteries supporting an increased action in the course of them, may be considered as the proximate cause of inflammation, at least in all cases not arising from direct stimuli applied; and, even in this case, the stimuli may be supposed to produce a spasm of the extreme vessels.

The following is a brief account of Dr. John Thomson's (*a*) observations on the variation of the current of the blood through the capillaries, resulting from the application of different substances:—"Weak and strong spirits of wine were applied to the smallest arteries of the web in eight or nine different frogs, but without being able to perceive any sensible change in the diameters of the arteries to which the spirits were immediately applied, though the general circulation through the web seemed to be increased by each application of the spirits. The results were the same when the tincture of opium was employed." Weak volatile alkali, or ammonia, produced "a complete contraction in the arteries to which it was more immediately applied. In upwards of one hundred experiments the contraction produced took place in *less than two* minutes after the application of the ammonia. In thirteen experiments contraction did not take place till after a period of *three* minutes. In three or four instances only, in which the ammonia was applied, were the contractions not induced." (p. 83.) "In some instances I thought I could perceive an *increase* of the velocity of the general circulation immediately after the application of the ammonia; in others, this increase, if it took place, *was so small as to be imperceptible:* but the first and most remarkable visible effect of the contraction of the artery from the application of ammonia was a *diminution of the velocity* of the circulation in the capillary vessels with which the contracting artery communicates. When the contraction is complete, a *temporary* stagnation in the capillaries with which the contracted artery immediately communicates is *often* produced. * * * In all these experiments, in which ammonia alone was applied, a paleness rather than redness of the web in the foot of the frog was produced; but this paleness was only of short duration." (p. 84.) "In applying a saturated solution of common salt to the arteries in the web of the frog's foot, I was not a little surprised to observe that these arteries, instead of being contracted as they had uniformly been by the application of the ammonia, were actually and sensibly

---

(*a*) Lectures on Inflammation.

dilated. The part of the web to which the salt was applied became of a red colour, and this redness, which was visible to the naked eye, lasted in general from a period of three to five or more minutes. It was impossible to view the part with the naked eye, without conceiving it *to be inflamed*." **Thomson** hoped, from "the facility of producing, by the application of salt, a state so accurately resembling inflammation that, by examining the phenomena of the circulation in this state, he should be able to arrive at some satisfactory conclusions with respect to the comparative velocity of the blood in healthy and in inflamed vessels; but he did not upon trial find this so very easy as he had at first imagined. (p. 85.) "The principal difficulty in ascertaining the comparative velocity of the blood in the sound and in the red or apparently inflamed parts arose from the very *variable* results which the application of salt produced in different animals, and in the same animal, in different circumstances." Thus, in nine cases, "the application of the salt was not only followed by a bright red colour visible to the naked eye, and a sensible enlargement of the arterial and venous branches, but with an increased rapidity of circulation also in the capillary vessels. * * * The repeated application, however, of the salt to the same vessels was *always sooner or later* followed by *retarded* capillary circulation, or even by *complete stagnation*. A second general result from the application of the salt was an apparent increase of circulation in the arteries and veins, with a diminution of velocity in the capillary branches. * * * In no one experiment have I been able to perceive any enlargement of an artery during the momentary influx of blood into its canal. The third and *most frequent* result from the application of salt was *diminished* rapidity of circulation in arteries, veins, and capillaries. In seventeen experiments the circulation became *so slow* as to stop altogether in the capillaries, and this stagnation, which usually goes off in a few minutes, continued in some instances for several hours. The enlargement of diameter in arteries, veins, and capillaries is very conspicuous: they may be said to be distended. * * * In every experiment with salt, whether the velocity of the circulation was increased, diminished, or stopped, the diameters of the blood vessels were *uniformly enlarged*, and this increase of diameter continued till the redness spontaneously disappeared." (pp. 86, 7.) From these observations **Thomson** comes to the conclusion, that, "If this view of the state of the circulation in inflamed vessels be just, it will follow that inflammation is sometimes attended by an increased, and at others by a diminished velocity in the circulation through the capillary vessels of the inflamed part, and, consequently, that neither of those two states ought to be included in the definition which we give of inflammation." (p. 88.) These experiments and conclusion of Dr. **Thomson** are mentioned, because they are the first by which the condition of the vessels and the state of the circulation under inflammation have been attempted to be explained: but they are inconclusive; for, as observed by J. W. **Earle** (*a*), "although that state of parts which was induced by the application of salt, viz. retardation and stagnation of the blood, presented the strongest resemblance to inflammation, yet in no one instance did either state continue for a sufficient length of time to allow any one of the usual accompaniments of inflammation (to wit, the effusion of lymph or pus, or mortification) to be produced, since each variation terminated more or less speedily in the restoration of the natural current." (p. 40.)

Dr. W. **Philip** (*b*) applied "to the web of a frog's foot, placed under a microscope, distilled spirits, and in a few seconds observed the blood in all the vessels moved with a greatly *increased* velocity, which, as he constantly kept the web wet with the distilled spirits, continued as long as he observed it, ten minutes or a quarter of an hour; but during no part of the time could he perceive the *slightest symptom* of inflammation, either with or without the microscope. The vessels, instead of appearing redder and more turgid, were evidently paler and smaller than before the application of the spirits." (p. 30.) Hence it appears that his experiment does not in its result tally with **Thomson's**, who at first did not observe any increased velocity, nor ever any sensible change in the diameter of the arteries. It is probable that in neither case did the spirit operate beyond constricting the parts by the cold its evaporation produced. In another experiment, however, inflammation was produced in the web of a frog's foot, and then Dr. W. **Philip** (*c*) "found the vessels of the part greatly dilated and the motion of the blood extremely languid. In several places where the inflammation was greatest, the vessels were most distended and the motions of the blood were slowest." (p. 15.) He therefore considered that in inflammation the blood vessels were in a state of debility.

(*a*) On the Nature of Inflammation, &c.

(*b*) An Experimental Inquiry into the Laws of the Vital Functions. London, 1826. 8vo.

(*c*) Introduction to a Treatise on Symptomatic Fevers, including Inflammations, &c. 4th Edit. London, 1820.

The account given by **Gendrin** (*a*) of the steps by which the stagnation of the blood in inflammation is produced is very interesting:—"The capillaries around this (irritated) point dilate, and seem to multiply themselves; because a greater number is perceived on account of the presence of red blood, which, in colouring them, renders them more visible. The globules arrive; they are crowded together, their motion is retarded, and at length suspended; they *revolve upon themselves*, and at last remain entirely at rest. The capillary circulation is then evidently suspended in the point irritated; for some distance around, the retardation of the circulation and dilatation of the capillaries are plainly seen; a little farther off the circulation is more rapid, the capillaries being still dilated, and the globules of the blood less distinct; finally, at the limits of the inflamed areola the circulation is, on the contrary, accelerated, the capillaries dilated, and the blood contains a greater number of globules. All these changes may take place in four or five minutes, and the same space of time is sufficient to allow of the capillary circulation returning to its natural state." (vol. ii. p. 475.) The objection made by **Earle** to **Thomson's** experiment, that inflammation had not been excited, might perhaps, strictly speaking, be made use of here; but it is quite clear that the experiment had reached the turning point from healthy to diseased action.

Thomson's experiments have been repeated and detailed by **Travers**, in his chapter, *Direct Effects of Stimuli and of Wound*, and all coincide in producing the same phenomena, excepting that with ammonia; in which **Travers's** observations are remarkably opposed to those of **Thomson**; for "the application of ammonia," says he, "produced an *instant increase of velocity*, then stagnation, with the deepened tint of colour and enlargement of vessels." (p. 36).

Travers gives a very beautiful account of "the oscillation attending the recovery of the circulation, which seems to be the *punctum saliens*, or first movement towards the formation of the new circulation." (p. 166.) * * * "The first effect of a drop of stimulant fluid, or of a wound upon a transparent web, (frog's foot,) as seen in the field of a powerful microscope, is," says he, "to arrest the circulation at the part. Around the point of absolute stagnation, the column of blood oscillates, and the particles are seen to separate and congregate in small irregular masses, presenting varieties of shape, some being perfect ellipses, others spherical. The vessels are dilated, and, in proportion, their fulness is increased, and their pink colour heightened. Still more remote from the stagnant centre increased activity of circulation prevails. The point of stagnation, the very slow circulation in the part immediately surrounding it, the current still oscillating in parts, and beyond this the more rapid and vigorous circulation, are manifested for several days. The contrasted appearance of one portion of the web stationary, and another in brisk circulation, is striking. The labour also of the current, the sudden overcoming of the obstacle occasioned by a too crowded passage, and the instant velocity succeeding thereupon, reminds us of the swaying backward and forward, and at length the inrush, of a crowd emerging into an open space from a narrow avenue." (p. 34, 35.)

Bennett says:—"It is very difficult to determine the cause of oscillation in the column of blood. It may be remarked, however, that this phenomenon has only been observed in the smaller animals which are held fast under the microscope. Even here the oscillation is not invariably seen to precede the stoppage. It is most frequently observed, also, when the animal is very weak, or has fallen into asphyxia. Under such circumstances the energy of the heart and large vessels is evidently diminished, and the blood will be propelled with less force than usual against the capillaries, and either stop for a moment, or flow backwards during the diastole of the heart. It is probable, therefore, that the oscillation does not essentially belong to inflammation, but rather depends upon the general weakness of the animal." (p. 33.)

The phenomena attending the first steps of the inflammatory process excited in the web of a frog's foot, as seen under the microscope, are well described by **Wharton Jones** (*b*). "Very soon after the irritation," he says, "accumulation and stagnation of the blood in the capillaries, including the terminations of the arteries and radicles of the veins of the part, is observed to take place; but, amidst the obstructed vessels a few here and there may still be seen pervious, and through them the stream of blood is very rapid. The accumulation and stagnation of the blood in the small vessels is always preceded by a retardation of its flow (coincident with dilatation of the vessels;) this retardation of the flow of blood having or not been preceded by the opposite condition of an accelerated flow (coincident with constriction of the vessels.)" He then proceeds to inquire into "the behaviour of the blood during the retardation of its flow and at

---

(*a*) Hist. Anat. des Inflammations.

(*b*) Report.

the time of its stagnation," which he thus describes:—"a. *Colourless corpuscles.* During the retarded flow of blood immediately preceding stagnation, an accumulation of colourless corpuscles is observed to take place on the inner surface of the walls of the dilated small vessels, similar to what occurs in the healthy state when the velocity of the stream of blood is diminished. b. *Red corpuscles.* While the accumulated colourless corpuscles may have even become stagnant on the walls of the vessels, the red corpuscles, though in increased quantity, in proportion to the plasma, still continued to float on, but more and more slowly until complete stagnation ensues. They are somewhat more collapsed than natural; hence they appear redder, and their nucleus is less indistinctly seen, a change similar to what takes place in the red corpuscles of newly drawn blood. The red corpuscles appeared to be the agents principally concerned in the stagnation of the blood * * * by agglomerating together, and applying themselves here and there flat against the walls of the vessels and adhering to them; whilst other red corpuscles applied themselves to those already adherent." (p. 568, 9.) This view had been already put forward by JONES in 1842; and about the same time was described more at length by EMMERT and by VOGEL. The following is the brief account which JONES gives of their statement. According to EMMERT, the colour of the red globules becomes somewhat deeper, and hence individually they appear less transparent; their surface is less smooth, and the irregularity of their edges is peculiarly distinct: they acquire the property of remaining adherent to each other and to the walls of the vessels when they come in contact with them. When the flow of blood becomes retarded and oscillations commence, the blood-corpuscles apply themselves, according to VOGEL, more to each other; and, though still individually distinguishable, they still touch, and in the smaller capillaries are often pressed close together by their surfaces in the manner of rolls of coin. The space next the walls seems merely filled with plasma; but, in complete stagnation of the blood, it disappears, and the interior of the vessel is completely filled with blood-corpuscles closely aggregated, and forming an apparently homogeneous indistinctly granular mass, in which individual blood corpuscles can scarcely be distinguished: but this fusion is merely apparent; for, if the blood be evacuated by opening the vessels, the individual corpuscles again appear quite distinct." (p. 568.)—J. F. S.]

5. Every injury which acts as an irritant upon any one organic part, may be considered as an incidental cause of inflammation. The necessary intensity of this irritation cannot, in general, be determined; it depends upon the individual susceptibility and condition of the organs. Powerful, young, full-blooded, sanguine, or choleric subjects, are most prone to inflammation; the disposition to which is strongest when the fibrin of the blood is increased in quantity. Inflammation arises most readily in parts which are very sensitive, and in which the capillary-vascular system is much developed. The usual incidental causes of inflammation are, a peculiar condition of our juices differing from the natural commixture, suppression of ordinary discharges, contagious matter, mechanical influences, falls, blows, wounds, and so on, cooling after preceding heat, burning by fire, corroding substances, and so on.

[To these we may also add, with JOHN HUNTER, "that fever is often the cause of local inflammation. We see this happen every day. * * * These inflammations, in consequence of fever, are commonly supposed to be critical; but I very much doubt the truth of this opinion." (p. 257.)

"Irritating substances," says JOHN HUNTER, "when of no specific kind, produce inflammation sooner than other visible causes of inflammation. If of a specific kind, then the time, sort, and violence will be according to that kind. But irritating applications must be continued for some time to produce violent inflammation. These differences are easily accounted for: quick death does not irritate the part killed, and the contiguous living part, not being itself hurt, is only irritated to get rid of the dead part. A wound is a quick irritation of a living part, so that it inflames more readily and more violently, according to the quantity of irritation; but that cannot be of long standing, as nature sets about procuring relief. But when irritating substances are applied, the part inflames quickly, according to their power of irritation; and, if they are continued, nature is not allowed to relieve herself, but is constantly teased, by which means the inflammation becomes also violent." (p. 257.) "All inflammations attended with disease have some specific quality which simple inflammation has not; and in such cases it is the specific quality which is the disease, and not the inflammation." (p. 260.) "There are many constitutions which have a tendency to specific diseases, that, when injured by fever or any constitutional complaint, readily produce the specific inflammation in such parts of the body as have the greatest susceptibility for any specific action; or, if such parts are affected by any local violence, the parts affected will not go through the healthy adhesive inflammation, nor will they enter into the healthy suppurative inflammation, but will fall into the specific inflammation peculiar to the habit: such is the case with an erysipelatous habit. Or, if a specific inflammation has already taken place, any violence done to it, when already begun, will increase that disposition and action, which we plainly see to be the case with the scrofula, because this disease can, and often does, arise from such a cause alone." (p. 261.)]

6. The *results* of inflammation are *resolution*, *exudation*, *suppuration*, *ulceration*, *induration*, *and various other transformations of organs*, *softening*, and *mortification*. All these conditions, excepting resolution, are merely different living processes, which are brought about by inflammation, and are still accompanied by it for a long time.

7. In Resolution (*Resolutio*, Lat.; *Zertheilung*, Germ.; *Résolution*, Fr.) the appearances of inflammation subside nearly in the same order as in their development they set in with, and the diseased part reverts to its natural condition. The pain diminishes, or disappears first; in the same degree the temperature and the redness lessen, the swelling alone often remains for a still longer time, till the absorption of the serous or albuminous fluid poured into the cellular tissue is completed.

We may hope for this result when the inflammation has not quickly run on to a great extent, the pain neither particularly severe nor throbbing; and when the fever accompanying the inflammation terminates critically in perspiration and deposit in the urine.

Resolution is distinguished from the *disappearance* or *recession* (*Verschwinden* oder *Zurücktreten*, Germ.; *Délitescence*, Fr.) of inflammation, which is in general connected with its simultaneous or speedy development in another organ. This recession depends on the succession of an irritation which is more severe than that which kept up the earlier inflammation. It is often merely a state *of changed vital activity*, of increased sensibility, which produces the removal of the inflammation, particularly if it be treated with repelling astringent remedies. Certain inflammations, as erysipelas, and critical inflammations, have a peculiar disposition to recede.

[The process of resolution has been well described by Dr. J. H. BENNETT, as follows:—"Resolution or absorption of the exudation may occur in various ways, and follow any of the transformations of the exudation except the one which converts it into permanent tissue. The early phenomena first disappear; the capillaries recover their contractility; the attraction between the blood and the parenchyma ceases; and the blood within the vessels begins to oscillate, and at length flows in a continuous stream. Secondly, the essential phenomenon disappears, no further exudation takes place, and that already poured out is absorbed. It occasionally, though rarely, happens, that the exudation does not coagulate for some time after it is exuded. Under these circumstances, when the early phenomena terminate, it re-enters the vessels by endosmosis, unchanged. In the majority of cases, however, it coagulates, and, once rendered solid, it could never be absorbed without the occurrence of changes in it by which it is again rendered fluid. This is effected by the formation, ripening and disintegration or decay (moulting process of SCHULZ) of nucleated cells, whereby the coagulated exudation is broken up, made soft, pultaceous, and diffluent, and at length absorbed. By this process exudation poured out into the lung or brain gradually disappears, by the production of inflammatory softening. On the serous surfaces the fluid and broken down corpuscles are absorbed; but that portion which passes into permanent organization, is transformed into fibrous tissue, becomes covered with a smooth membrane, so that the functions of the organ are not disturbed. Abscesses when resolved undergo a similar process. The pus-cells, instead of being evacuated, are brought closely together from the absorption of the more fluid portion (*liquor puris*.) These are gradually broken down, the cell-walls are dissolved, and the whole is reduced to a molecular matter, which re-enters the vessels, and thus complete resolution is produced. The disintegration of pus-corpuscles previous to absorption is evidently favoured by the pressure which the abscess receives from the contraction of the filamentous and elastic tissues that form its walls. * * * It is probable also, by increasing the contraction of the integuments, as well as by removing fluid from the neighbourhood of the part, that irritants, blisters and cauteries, are so beneficial in the resolution of abscesses. It is suggested by ZIMMERMAN, that the formation of an acid, as the lactic, in abscesses when fully formed, favours their disintegration. We have seen that acetic acid dissolves the cell-walls and causes the nucleus to appear in the form of granules: if lactic acid be produced, it would probably have the same effect. Alkaline solutions also, it is well known, dissolve pus-corpuscles, a circumstance that may explain the discutient effects of alkaline lotions and washes, and their beneficial operation in removing the incrustations from eruptive pustular diseases." (p. 63–5.)

As to the question "What becomes of the molecular fibrin which thus re-enters the circulation?" BENNETT states that "the observations of several German physicians, more especially of SCHÖNLEIN and ZIMMERMAN, have thrown much light upon it, and determined that the changes which the urine undergoes in acute inflammatory diseases, bear a relation to the absorption of exuded blood-plasma in internal organs. Thus, in a case of pneumonia, SCHÖNLEIN pointed out that the disappearance of dulness was accompanied by a turbid state of the urine, which contained a large amount of molecular fibrin, and was also highly coagulable by heat. ZIMMERMAN has recorded instances where the turbidity and coagulability of the urine bore a marked relation to the diminution of suppurative swellings. In some cases where purulent matter was apparently absorbed, he had observed that the urine was coagulable from the presence of fibrin dissolved in it" (*a*). Hence it is concluded "that the molecules of the broken-up exudation, after circulating in the blood, are frequently eliminated by the kidneys, and make their exit from the system by the urine, sometimes entire, at others in a state of solution. * * * Occasionally the excess of fibrin may be eliminated by the skin, lungs, and bowels. In all cases it constitutes an important symptom of the crisis." (p. 65.)]

8. Exudation (*Exsudatio*, Lat.; *Ergiessung*, Germ.; *Exsudation*, Fr.) is the outpouring of a larger quantity of serous fluid than the capillary vessels ordinarily exhale into the cellular tissue, into the parenchyma of organs, or into the cavities of the body. For the most part it occurs towards the end of the inflammation, or at least when it is subsiding. The fluid poured out (serum and coagulable lymph) differs in respect to its composition; often thin and transparent, often consistent, mingled with flocculi, and so on. The thicker part of this exudation (the coagulated albumen) not unfrequently unites neighbouring parts, vessels are prolonged into this interstitial substance, and *adhesion* is effected. If the fluid poured into the cellular tissue be only serous, then *dropsical swelling* (*œdema*) is produced. The exudation occurs, especially often in serous membranes: not unfrequently also does a similar exudation accompany inflammation of the mucous membranes. These exudations may be accompanied by an inflammatory or weakly condition of the capillary vessel.

[The term "exudation," as here explained by our author, is synonymous with "effusion," as generally employed by British practitioners; but the latter, by defining the nature of the matter poured out as effusion of serum, of coagulable lymph, &c., make a distinction which the former does not. Neither of these terms, however, thus used, seem sufficiently pointed; but their employment as proposed by J. HUGHES BENNETT is unobjectionable. "*Effusions*," he says, "no doubt are very common; but, in the great majority of instances, they arise from venous obstruction, altogether independent of inflammatory phenomena. * * * In all such cases the fluid is clear, holds no fibrin in solution, and on being evacuated shows no disposition to coagulate. * * * In inflammatory effusions, on the other hand, the fluid is more or less turbid, containing fibrin in solution, and, if allowed to stand, flocculi swim in it, or sink to the bottom of the vessel. * * * Mere effusion, then, cannot itself be considered as characteristic of inflammation. It may be the result of congestions non-inflammatory, or, if otherwise,

---

(*a*) Ueber den gerinnbaren Harn; in CASPER's Wochenschrift, 1843, p. 345.

passes more or less into exudation. In every instance of undoubted inflammatory action an *exudation* of blood-plasma occurs which may be made visible. * * * Where the *liquor sanguinis* is poured out into shut cavities, the same phenomena occur as when blood is drawn from the body. The fibrin coagulates, and the serum is set free. The former then lines the serous membrane, and is denominated coagulable lymph, whilst the latter is called serous effusion. * * * In parenchymatous tissues, however, as in the lungs, liver, brain, &c., the structure of the parts will not allow of this distinct separation. The *liquor sanguinis* exuded is, of course, at first fluid, and, in this state, insinuates itself among the elementary structure of the organs, filling up every minute space. When it coagulates, the tissues of the part affected are completely blocked up, as if with cement. The blood-vessels, nerves, filaments, &c., are surrounded by a solid mass, in the same manner that the stones in a wall are surrounded by mortar." (pp. 38, 40.)

As to he effusion of serum, TRAVERS observes:—" The first change external to the vessels in inflammation is not a permanent change, and looks like a measure of temporary relief to the over-loaded vessels which surround the inflamed centre. It is an aqueous exudation from the colourless capillaries into the adjoining cellular texture. It would seem to be a passive mechanical effect, as it doubtless often is, but for the precedence of other unequivocal signs of inflammation." (p. 65.)

WHARTON JONES says:—" Immediately after or during the stagnation of the blood, exudation commences. From being at first serous the exuded fluid comes at last to be pure plasma, at least a fluid containing a greater or less quantity of fibrin." He attributes the exudation " to the thinning of the walls of the vessels, from their relaxation and dilatation on the one hand and the pressure from within the vessels on the other:" and he also suggests, as likely to promote exudation, " that the plasma will be pressed out from among the aggregating corpuscles, even when the blood would not, if out of the body, present the buffy coat, and that because within the body the fibrin of the plasma does not so readily coagulate;" but, when the blood is so changed that on abstraction the buffy coat appears, " the plasma at the same time that it is more quickly and energetically squeezed out from among the aggregating red corpuscles, will present itself in greater quantity and richer in fibrin, for transudation through the walls of the capillaries." He considers, with WATSON, that the cause of serum alone passing out first, " is, as in common œdema, owing to obstruction; the obstruction in inflammation being from the stagnation of the blood;" but how obstruction determines exudation of serum alone, remains a question: to help to a solution of this, it may be stated that, according to KÜRSCHNER, water passes most quickly through animal membranes and saline solutions more quickly than viscid, gummy, and albuminous solutions. With exudation," he says, " is completed the inflammatory process properly so called." (pp. 584, 5.)

" The extravasation of the serum along with the coagulating lymph," says JOHN HUNTER, " is, probably, not a separation of itself, as in a dropsy; but, a part of it being separated from the lymph in the coagulation of that fluid, is squeezed into the surrounding cellular membrane, where there is but little extravasation, and where the cells are not united by it. Thus, the circumference of such swellings is a little œdematous; but the whole of the serum if there be a depending part will move thither, and distend it considerably, as in the foot in consequence of an inflammation in the leg. But, in most cases, there is a continued extravasation of serum long after the extravasation of the coagulating lymph is at an end, so that depending parts will continue œdematous, while the inflammation is resolving, or while suppuration, or even healing, is going on. The whole swelling looks like a part of the body only a little changed, without any appearance of containing extraneous matter; and indeed it is simply formed by an extravasation of fluids without their having undergone any visible or material change, except coagulation." (p. 285.)

GERBER speaks of the exudations after inflammation as *watery* or *serous* exudation when merely the serum of the blood is poured out; *plastic*, when the *liquor sanguinis* containing fibrin exudes without the blood-corpuscles; and *sanguineous*, when it is blood-coloured; the colour depending either on solution of the colouring matter of the blood, or the effused *liquor sanguinis* contains all the components of the blood and even the blood-globules, thus forming the transition to hæmorrhage (p. 42.) He says, also, that in the fluid of *serous exudations* albuminous granules of albuminous fluids are usually found; that after *plastic exudations* a yellowish turbid fluid is found in the affected cavity, with fine pale yellow flocculi floating in it, or precipitated upon and perhaps adhering to the walls of the exuding surface. If the exudation of plastic matter go on longer, and the quantity of effused *liquor sanguinis*, be considerable, the cavities may be filled with it; their walls and the organs they include may be covered with thick layers of fibrin, which at first is of a pale yellow hue and somewhat transparent, with the consistency of imperfectly coagulated albumen. If death then occur, this hyaline substance quickly becomes granular, and, in consequence of chemical decomposition, is dissolved in the serum; but, if life continue, the characters of the exudation are otherwise altered (p. 42;) which alteration he proceeds to describe as follows:—"The separated serum is gradually absorbed whilst the fibrin floating in it is dissolved. The fibrin which is attached, on the other hand, becomes of a chrome-yellow colour, and, if examined under the microscope, is found to consist of a connected exudation of corpuscles, which are found in form twenty-four to thirty hours after the exudation, when the mass is of an orange yellow, and has acquired such consistence as to be stripped off the membrane in slips. * * * The exudation-corpuscles are in every respect the same as the lymph-corpuscles; they generally form many superimposed layers, being laid flat one over another, and so constituting membranes which completely resemble the tessellated epithelium when the connecting medium has disappeared, so that the edges of the primarily round corpuscles thrust against each other, and are thus rendered polygonal." Subsequently the cohesion increases, and a more fibrous structure is indicated, and "under the microscope an ever-increasing linear arrangement of the exudation-corpuscles, which are more intimately united at two opposite points in one line, by means of the connecting cyto-blastema than any where else, is apparent. The original globular cyto-blasts now assume a spindle-like form, and the flat ones continue more flatted as their margins have become more spindle-shaped, and in their linear connexion form varicose fibres, at the enlargements of which the nucleus of the exudation-corpuscle continues visible, and either subdivides into several granules, or a new nucleolus is formed within it. Between these now formed cellular fibres there still remains an inter-cellular hyaline substance, so that the masses may be separated mechanically in any direction." (p. 434.)

VALENTIN (*a*) describes the exudation-corpuscles as "like so many embryonic nuclei —round, granular, and lying tessellated one upon another, whilst their very small interstices contain a transparent gelatin." (p. 215.)

GULLIVER (*b*) differs from GERBER as to the similarity between the exudation and lymph-corpuscles. "In mammiferous animals," he says, "it has always appeared to me that the lymph-globules differ in size, structure, and chemical characters from exudation-globules. The latter are larger, more irregular in size and shape, more spongy or loose in texture than the former;" generally exhibit two or three nuclei when treated with acetic acid, whilst the lymph-globules are only rendered slightly smaller by it. The acid either dissolves or makes remarkably fainter the comparatively thick shell of the exudation-corpuscle, while the lymph-globule becomes more distinct when subjected to the action of the acid." * * * "The lymph-globules, in fine, in progress of development, may soon become more or less coated with fibrin; but, if examined at an early period, they will be found to resemble in chemical characters the nuclei (nucleoli of VALENTIN) of primary cells." (p. 83.)]

9. Suppuration (*Suppuratio*, Lat.; *Eiterung*, Germ.; *Suppuration*, Fr.) is, when resolution does not ensue, the suitable termination of simple inflammation, and, if that be severe, it appears the natural result; therefore, a *fully developed simple inflammation* is termed, by some, *suppurative inflammation.* The pus is secreted through the walls of the capillary vessels, not, however, immediately as such, but is first formed by the changes which the inflammatory exudation undergoes; the coagulated fibrin is gradually converted into pus-globules, which then mix with the serum. Pus is formed of all the components of the blood, the colouring matter excepted, and especially from its albumen and fibrin. If it collect in the cellular tissue, *Abscess* (*Eitergeschwülste*, Germ.; *Abcès*, Fr.) is produced. The process of suppuration is a true secretion, and the vital condition of the organs influences it as well as all other secretions. There is usually no destruction of tissues connected with suppuration. That we often find the remnants of destroyed cellular tissue in pus, or that the skin

(*b*) His notes in the Translation of GERBER.

covering the abscess is destroyed, depends on accidental circumstances—in the great distension of the cellular tissue and skin, or in the suppuration, from general or local mischief, passing into *Ulceration* (*Verschwärung*, Germ.; *Ulcération*, Fr.) These remnants of destroyed cellular tissue must not be confounded with the *cores* (*Eiterpropfröpfen*, Germ.) so called *sloughs*, which are found in the midst of the inflamed cellular tissue, at the commencement of suppuration, in the form of white jelly-like semi-transparent stringy flocks, which have no trace of organization, are at first firmly connected with the surrounding cellular tissue, but subsequently are thrown out with the pus. These cores are tough concretions of coagulated albumen.

The various opinions relating to the formation of pus may be arranged in two classes:—1. It was supposed that pus was formed and secreted within the vessels of inflamed organs by the peculiar activity of the former. 2. That pus was produced externally to the vessels of the inflamed organs, either in the solid parts in a state of inflammation, or in the effused fluids undergoing a change similar to that of fermentation or putrefaction. According to the former opinion suppuration must be considered as a vital, according to the latter as a chemical, process. The formation of pus as a secretive process first published by SIMPSON (*a*), more fully discussed by DE HAEN (1756,) and by MORGAN (*b*), was specially and more accurately proved by HUNTER, by BRUGMANS (*c*), and by PINEL. Upon the other supposition BOERHAAVE ascribed the formation of pus to the dissolving of the hard parts and the changes which take place in the effused blood; BELL and others to the putrefaction of the serum; GOTTER and QUESNAY, to the change in the coagulable lymph; HOFFMAN and GRASHUIS, to the decay of the fat; and STEWART to putrefaction of the chyle.

The process of the pus formation and the nature of pus, besides the above-mentioned writers, most meritoriously occupied PEARSON (*d*), HEWSON (*e*), E. HOME (*f*), BERZELIUS (*g*), GRUITHUISEN (*h*), and have been recently examined with the greatest care; FISCHER (*i*) has furnished observations on its chemical composition; DONNE (*k*), GLUGE (*l*), and VALENTIN (*m*) have enriched our knowledge of its microscopic elements; GUTERBOCK (*n*), WOOD (*o*), BONNET (*p*), and MANDT (*q*) have, in a chemical and microscopical view, furnished correct observations, which VOGEL (*r*) for the most part arranged and increased with the results of his own observation. Compare also VOGEL (*s*) and E. V. BIBRA (*t*).

10. The transition of inflammation into suppuration is probable—when the inflammation is active and quickly reaches an acute stage; when the pain is severe, the distension and swelling are considerable, the inflamed part of a lax character, and surrounded with much cellular tissue (1). If the inflammation continue longer than usual, without showing critical movements, if the pain becomes throbbing, the redness and swelling diminish without entirely disappearing, the swelling becomes softer, and the patient has a shiver, then the formation of pus has commenced; the swelling becomes still softer, is elevated in the middle, and sunk at its circumference,

and on touching it *fluctuation* (*Schwappung*, Germ.) is felt. In order to be assured of this, the fingers may be pressed alternately upon the swelling, or, what is preferable, the finger or the flat hand may be laid on the side of the swelling, while this is gently tapped with the fingers upon the other, by which the undulations of the pus are communicated to the hand. The skin becomes transparent at the most elevated part, and the pus is seen through it; finally, the skin breaks by the process of continued absorption, and the pus is discharged. If the parts covering the abscess are unyielding, an extension of the suppuration takes place in various directions before it makes its way out (2). If the inflammation be slight, it often continues a long time without exhibiting any disposition to break. It is often very difficult to distinguish the transition to suppuration in inflammation of deeply situated or in internal organs. The usual appearances are—the symptoms of inflammation subside without crisis, the part does not return to its natural functions; it feels to the patient heavy, oppressive, or cold; he has frequent shiverings; the appearances of hectic fever set in, burning heat of the hands and soles of the feet, especially after eating, circumscribed redness of the cheeks, emaciation, night-sweats, purgings, and so on. Deep-seated fluctuation is felt, or the surface of the part exhibits an œdematous swelling. The symptoms of hectic fever accompany every considerable suppuration, and it is probable that this must be ascribed partly to the loss of the albumen and fibrin of the blood, and partly to the absorption of pus.

The circumscription of the pus in the cavity of the abscess depends upon the effusion and coagulation of the plastic lymph, which occur during inflammation, whereby a cavity with smooth walls is produced, in which the capillary vessels are very strongly developed, so that the pus is shut off from the other cellular tissue, and its spreading from cell to cell is prevented. In cases in which the inflammation is not connected with plastic exudation this circumscription of the abscess does not take place; for instance, in many erysipelatous inflammations. If suppuration occur on the surface of serous membranes, there must always be first produced a considerable development of vessels. In structures which are very highly vascular, suppuration occurs more rapidly. The walls of the abscess must be considered as *secreting* and *absorbing* surfaces. In the resorption of pus, (by the veins and lymphatic vessels,) it is mixed with the blood and separated from it by the colatories of the body, specially the lungs and kidneys, or is deposited in the tissue of parts (metastatic abscesses;) it is, however, undetermined whether the pus is deposited as such or is produced by the after-changes which commonly occur in the inflammatory exudation (Vogel.) As the pus-corpuscles are larger than those of the blood, they cannot pass through the capillary vessels, and therefore only the serum of the pus is absorbed, or the pus-corpuscles are broken down, and can then also be absorbed. We must not confound with this the entry of pus into a torn vein, or its formation by phlebitis in the vein and its further passage onwards with the blood. In regard to the operation of absorbed pus, Bonnet supposes that the absorption of good, cream-like pus, which has not been changed by the action of the air, will not produce any peculiar symptoms, because with it nothing enters into the blood but what is natural to it; but, if in depraved putrid pus hydrosulphate of ammonia be developed with a residue of ammonia, and be absorbed with the serum or pus, a septic poison is introduced into the blood, the presence of which has been ascertained by Bonnet in the blood, and its separation in the urine.

[(1) "The true inflammatory disposition and action," says Hunter, "almost immediately ceases upon the commencement of suppuration; and, although the vessels may be nearly in the same state, yet they are in a much more quiescent state than before, and have acquired a new mode of action." * * * And he asserts, "as an invariable fact, that no suppuration takes place which is not preceded by inflammation; that is, no pus is formed but in consequence of it." * * * "The immediate state of parts which may be called the immediate cause of suppuration, I conceive to be such as cannot carry on its usual functions of life, and which state of parts I have called the state of imperfection, let the cause of that state be what it will; we have shown that irritation simply is not always sufficient, it often only brings on the adhesive stage, which is in most cases intended to prevent the suppurative." (p. 372.) " In spontaneous suppurations, one, two, three, or more parts of the inflammation lose the power of resolution, and assume exactly the same disposition with those of an exposed surface, or a surface in contact with an extraneous body. If it is in the cellular membrane that this disposition takes place, or in the investing membranes of circumscribed cavities, their vessels now begin to alter their disposition and mode of action, and continue changing till they gradually form themselves to that state which fits them to form pus; so that the effect or discharge is gradually changing from coagulating lymph to pus: hence we commonly find in abscesses both coagulating lymph and pus, and the earlier they are opened, the greater is the proportion of the former." (p. 378.)

" Should the exudation become purulent, this gelatin (viz. that which is interstitial to the corpuscles) acquires fluidity," says Valentin, " and the plus globules then swim in the *liquor puris*, sink tessellated to the bottom, and surround themselves with cells, which subsequently undergo tranformation in accordance with certain laws into exudation fibres or exudation membranes." (pp. 215, 216.)

" This (suppurative) inflammation has symptoms common to inflammation in general; but," says Hunter, " it has these in a greater degree than the inflammation leading to it, and has also some symptoms peculiar to itself: * * * it gives as much as possible the idea of simple pain without having a relation to any other mode of sensation: * * * the pain is increased at the time of the dilating of the arteries, which gives the sensation called throbbing, * * * perhaps one of the best characteristics of this species of inflammation. [This observation, as already noticed, (p. 23,) is incorrect.—J. F. S.] When the inflammation is moving from the adhesive state to the suppurative, the pain is considerably increased (and which would seem to be the extent of this operation in the part;) but when suppuration has taken place the pain in some degree subsides. * * * The redness that took place in the adhesive stage is now increased, and is of a pale scarlet: this is the true arterial colour, and is to be accounted a constant symptom, as we find it in all internal inflammations, when at any time exposed, as well as in those that are external." The dilatation of the old vessels, and the formation of new ones, which had occurred in the first or adhesive state of the inflammation, " are here carried still further in the surrounding parts, which do not suppurate, and constitute two other causes of this redness being increased by the vessels becoming more numerous, and the red part of the blood being pushed more forward into many vessels, where only the serum and coagulating lymph went before. The part which was firm, hard, and swelled, in the first stage, now becomes still more swelled by the greater dilatation of the vessels and greater quantity of extravasated coagulating lymph thrown out in order to secure the adhesions. The œdematous swelling surrounding the adhesive gradually spreads into the neighbouring parts. * * * There is a certain period in the inflammation, when the suppurative disposition takes place, which is discovered by new symptoms taking place in the constitution, viz. shivering." (p. 377–79.)

" The vessels are but little changed from the adhesive state at the commencement of the suppurative disposition; so that they still retain much of the form they had acquired by the first state, the discharge being at the beginning little more than coagulating lymph, mixed with some serum. This is scarcely different from the adhesive stage of the inflammation; but, as the inflammatory disposition subsides, the new disposition is every instant of time altering those vessels to their suppurative state; the discharge is also varying and changing from a species of extravasation to a new formed matter peculiar to suppuration; this matter is a remove further from the nature of the blood, and becomes more and more of the nature of the pus; it becomes whiter and whiter, losing more and more of the yellow and green which it is apt to give the linen that is stained with it in its first stages, and in consistence more and more viscid or creamy." (p. 415.)

John Hunter describes that as " an abscess *in* this part," *i. e.* when " collections of matter are found in parts where not formed, more especially in the deeper-seated ones, the matter moving from the seat where it was formed to some more depending part, or, having met with some obstruction in its course, it takes another direction;" whilst " abscesses which are commonly formed where matter is found, especially the more superficial ones, may be justly called abscesses *of* this part. (p. 510.) " Suppuration takes place much more readily in internal canals than internal cavities; * * * more readily upon the surface of canals than in either the cellular or investing membrane. The same cause which would produce a suppuration in the first parts (the canals) would only produce the adhesive in the other (the cavities.)" (p. 377.)

"The cavity (of the abscess,)" observes **Travers**, "is surrounded by an effusion, and lined by a pellicle of lymph (pyogenic membrane,) whence the pus is furnished." (p. 125.) "The aspect of the suppurating membrane varies to such extent as scarcely to exhibit, in some circumstances and situations, the granular form, *e. g.* upon the walls of abscesses, and upon the free surfaces of mucous and serous membranes; but the fibrinous bed and the capillary loop of new formation, and a corresponding alteration of the pus-secreting surface from its normal state will always be detected upon careful examination, being essential elements of the suppurative process." (p. 111.) "A section of an abscess, from circumference to centre, presents the condensation of the wall by the deposit occupying the cells of the cellular membrane, the secreting membrane, the semi-solid flakes of lymph, and the collection of pus forming its contents; the arrangement, appearance, and proportion of each varying according to the stage of the suppuration." (p. 125.)

(2) Of the circumstances upon which depends the determination of abscess to the surface, the following very interesting account is given by John Hunter:—"An internal pressure, produced by an extraneous body, acts equally on every side of the surrounding parts, and, therefore, every part being pressed alike, ought from this cause alone to produce absorption of the surrounding parts equally on all sides, supposing the parts themselves similar in structure, or, which is the same, equally susceptible of being absorbed; but we find that one side only of the surrounding living parts is susceptible of this irritation: therefore, one side only is absorbed; and this is always the side which is next to the external surface of the body. * * * From this cause we find abscesses, &c., whose seat is in or near the centre of a part, readily determined to the surface on the one side, and not on the other; and, whenever the lead is once taken, it immediately goes on." (p. 448.) He also observes:—"We find that the absorption of whole parts more readily takes place, to allow an extraneous substance to pass out of the body than it will to allow one to pass in. Thus we see that the slight pressure produced by matter on the inside of an abscess has a great effect, and the matter is brought much faster to the skin (although very deep) than it would by the same quantity of pressure applied from without; and, indeed, so slight a pressure from without would rather tend to have an opposite effect, namely, that of thickening. The reason of this is evident: one is, a readiness in the parts to be freed from a disease already existing; the other is a backwardness in the parts to admit a disease. This principle, therefore, in the animal economy produces one of the most curious phenomena in the whole process of ulceration, viz. the susceptibility which the parts lying between an extraneous body and the skin have to ulcerate, while all the other side of the abscess is not irritated to ulceration; and the necessity there is that it should be so must be very striking; for, if ulceration went on equally on all sides of an abscess, it must increase to an enormous size, and too great a quantity of our solids must necessarily be destroyed." (p. 449.)

But mere pressure is not, according to Hunter's views, sufficient for bringing the contents of an abscess to the surface; "there is an operation," says he, "totally distinct, and this is a relaxing and elongating process, carried on between the abscess and the skin, and at those parts only where the matter appears to point. It is possible that this relaxing, elongating, or weakening process may arise, in some degree, from the absorption of the interior parts; but there is certainly something more, for the skin that covers an abscess is always looser than a part that gives way from mere mechanical distension, excepting the increase of the abscess is very rapid." (p. 460.) **Travers**, in commenting upon this point, observes:—"Whether the tendency of matter to the nearest surface, external or internal, the outer or inner integument, as the case may be, is due to the more yielding structure of parts in the direction of the nearest surface or to the operation of a physical law, as the increased amount of pressure from the increased area of the summit over the base, I cannot determine." (p. 188.)]

11. Pure good pus (1) is an opake, tolerably consistent, yellowish white fluid, with a peculiar smell when fresh, which it loses on cooling, and of a sweetish taste, specifically heavier than water, (spec. grav. 1,030,) (2), not readily subject to putrefaction (3); reacts in its fresh state as an alkali; but, after a time is neutral or acid, probably because during its decomposition it forms acetic acid; and under the microscope is seen to consist of *fluid parts* and *globules* (4) which can be separated by straining (5); but very frequently this separation occurs spontaneously if the pus be left alone.

[(1) Pus "is formed from some change, decomposition, or separation of the blood which it undergoes in its passage out of the vessels, and for effecting which the vessels of the part have been formed, which produces a subsiding of the inflammation from which it took its disposition. * * * In order to carry on the decompositions and combinations necessary for producing this effect, either a new or peculiar structure of vessels must be formed or a new disposition, and of course a new mode of action of the old must take place. This new structure or disposition of vessels I shall call glandular, and the effect or pus a secretion." (pp. 415, 416.)

"The purpose which the formation of pus serves in the economy is," says **Travers**, "in conjunction with another act of inflammation, to open a communication with a contiguous surface, either for the purpose of liberating matter incapable of organization, and therefore superfluous or hurtful; or as indispensable to reconstruction or the effacement of lesions by granulation. (p. 118.) The continuance of inflammation, beyond the term required for union in simple solutions of continuity, in cases which are beyond reparation by the direct adhesive process, and in phlegmon or adhesive deposit unaccompanied by external lesion, entails an addition of the suppurative to the adhesive action. (p. 124.)

(2) The principal peculiar qualities of pus are its colour and consistence; but it appears that the colour takes its rise from the largest portion of the whole mass being composed of very small round bodies, very much like those small round globules which, swimming in a fluid, make cream. "I should suppose," says **John Hunter**, "those round globules to be white in themselves as cream would appear to be, although it is not necessary that the substances of matter which reflects a white, should be itself white. * * * These globules swim in a fluid which we should at first suppose to be the serum of the blood, for it coagulates with heat like serum, and most probably is mixed with a small quantity of coagulating lymph; for pus in part coagulates, after having been discharged from the secreting vessels, as mucus is observed to do; but, although it is thus far similar to serum, yet it has properties the serum has not." The fluid part of the pus would not coagulate on the addition of the gastric juice, or of solutions of neutral salts, but only with sal ammoniac, (hydrochlorate of ammonia,) "which would not coagulate any other of our natural juices." The proportion of the white globules in the pus "depends on the health of the parts which formed it; for, when they are in a large proportion the matter is thicker and whiter, and is called good matter." * * * Pus is specifically heavier than water: it is probably nearly of the same weight with blood or any other animal substance rendered fluid. It has a sweetish and mawkish taste, probably from having sugar in it, which is very different from most other secretions. It has a smell in some degree peculiar to itself." (p. 428-9.)

(3) With reference to the putrefaction of pus, **Hunter** observes:—"Pus, from several circumstances often attending it, would appear in general to have a greater tendency to putrefaction than the natural juices have; but I very much suspect that this is not really the case with pure pus, for, when it is first discharged from an abscess, it is in generally perfectly sweet. There are, however, some exceptions to this; but these depend on circumstances entirely foreign to the nature of pus itself," (p. 434,) of which he instances the communication of the air with the interior of an abscess; the nearness of an abscess to the feculent contents of the colon, or rectum, when blood is contained in abscess resulting from external injury, or when part of the solids mortify from the same cause, and the like; "in all such circumstances we find the pus has a greater tendency to putrify than the pure or true pus," which, "although easily rendered susceptible of change by extraneous additions, is in its own nature pretty uniform and immutable. It appears so unchangeable that we find it retained in an abscess for weeks, without having undergone any change; but these qualities belong only to perfect pus." (p. 435.) Pus from sores, he remarks, is subject to the same changes under similar circumstances. **Gulliver** also states, that he has had healthy pus "in a window, to which the sun had access for six weeks, without becoming fetid, and, if carefully washed of all impurities, it will continue sweet for an almost indefinite time" (*a*.)

(4) **Thomson** says the globular structure of pus was first mentioned by **Senac** (*b*). The following is, I presume, the passage to which he refers:—"The globules of pus are similar to those of the blood: such as are seen in the matter of which gonorrhœa consists are larger, whilst those which form the pus of ulcers are smaller and more unequal in size: but this figure does not give redness to these globules; they are white, and this whiteness is constant." (p. 659.)

John Hunter describes as "the peculiar character of pus, globules swimming in a

---

(*a*) Med. Gaz., N. S., vol. ii. p. 312. 1839-40.

(*b*) Traité de la structure du Cœur, et son action et de ses Maladies, vol. ii. Sup. Paris, 1749. 4to.

fluid which is coagulable by a solution of sal ammoniac, (hydrochlorate of ammonia,) which no other animal secretion he knew of is." (p. 421.)

(5) This does not accord with Gueterbock's (*c*) observation, who says, that "Pus of every kind and from any part may be separated into two parts, into a liquor and a substance, not soluble in it, but only suspended, rendering the pus turbid, and tinging it yellow; which, however, I could not completely separate by straining, although the most different papers were used. For the fluid always flowed turbid, and the paper through which I strained being obstructed, the pus, diluted with water, began in a short time to putrify. But, if you allow it to remain for a longer time in one vessel, you will find a supernatant yellow fluid, the greatest part of which, as will be shown hereafter, consists of albumen." (p. 8.)]

12. The fluid (serum) of pus shows no trace of globules: it exhibits all the signs of albumen dissolved in water, which is distinguished, like the serum of the blood from the white of fowls' egg in not being thrown down by æther. This fluid also contains *fat*, *osmazome*, *acetic acid*, perhaps also *lactic acid*, *hydrochlorate of soda*, *of potash*, *of lime*, *of ammonia*, (Bonnet,) *phosphate*, *sulphate*, *and* probably also *acetate and lactate of soda*, *phosphate of magnesia and lime*, *a trace of iron and silica.*

Henle (*a*) found free fat, recognisable by the microscope, in form of fatty vesicles.

Whether many substances which are found in pus, such as pyine, gluten, &c., are proper constituents of that fluid seems still doubtful; as also whether the iron is not to be ascribed to some admixture of blood.

[Gueterbock has entered into the chemical analysis of pus at very considerable length, (pp. 11, 19,) and he describes "a new substance of peculiar character," to which, "although found not only in pus, but also in mucus, without any intermixture of pus, and in tubercular matter, he gives the name *pyine*, (from *πυος*, *i. e.* formed of pus,) because he first discovered it in pus." (pp. 12, 13.) In the translation of Gerber's Elements of General Anatomy (pp. 97, 100) will be found the analyses of Vogel, J. Martius, Gueterbock, Kock, Goebel, and Dumas.]

13. The globules of pus vary in quantity, sometimes a larger, sometimes a smaller number being present; the thicker and better the pus, the more numerous are the globules. They are of two kinds; the larger have a diameter of 0,0004—0,0005 of a Paris inch; are of pretty uniform size, usually tolerably round, rarely of irregular form: most of them have an irregular surface, so that they appear as if covered with still smaller globules; they are more transparent and less coloured than blood-globules. Between these larger globules swim about a smaller quantity of little granules, rarely as large as blood-corpuscles. If the larger pus-corpuscles are for some time in contact with water, they become more transparent towards the edge, darker in the middle, and the same in spirits of wine. In acetic acid the envelope becomes transparent, finally dissolves, and leaves behind a nucleus consisting of one, two, or three corpuscles of 0,0001 of a Paris inch in diameter, many of which have a central indentation. Sometimes also the envelope bursts, and the nucleus is set free by shaking or rubbing. The envelope consists of albumen.

According to Mandt (as above) the larger pus-globules, in respect to their size form, appearance, and their relation to chemical agents, exhibit a perfect accordance with those globules which the coagulated fibrin presents, either in inflammatory buff, in false membranes, or in the fibrils, which fibrin forms when the blood is shaken about with albumen. Mandt applies to these globules the name *fibrin-globules*, because they owe their existence to the coagulated fibrin which is secreted from the blood and external to the vessels. The second kind of globules, the diameter of which varies from $\frac{1}{400}$ to $\frac{1}{500}$ of a millimètre, and which are mixed with the pus-globules, belong to the globules of albumen coagulated by the salts of the serum: they are, therefore, more

---

(*a*) De Pure et Granulatione Commentatio Physiologica. Accedit Tabula ænea. Berol., 1837. 4to.

(*b*) Symbol ad Anat. vill. Berol., 1837, p. 24, *note*.

numerous as the serum is more rich in salts. They are frequently found among fat-globules of different diameters.

[GUETERBOCK appears to be the first who discovered the different size of the globules in pus; he says:—"All writers who have hitherto examined pus, KALTENBRUNNER (*b*) alone excepted, (who mentions that he has seen corpuscles and granules swimming in the pus of frogs, although in pure human pus, carefully preserved from the air, he states that he has sometimes seen granules of equal size, (p. 16,)) speak of the globules swimming in pus as of only one kind. I have, however, always seen globules of vastly different size in pus, of which only the largest have been noticed by writers, even by GRUITHUISEN and E. H. WEBER. Although these exist in the greatest number in pus, yet it is not to be doubted that smaller ones swim among them. The proportions of the globules and liquor vary in every kind of pus, so that the greater be the number of globules the thicker and better is the pus, and *vice versâ.*" (p. 8.) The size and form of the globules and granules given by CHELIUS are those stated by GUETERBOCK, who, subsequently comparing the globules in pus with the corpuscles of other animal liquors, says:—"They are most like the globules I have found in mucus, but more irregular, unequal, and of much less number, most of which are of the same size, and some even larger than the pus-globules, as I have frequently by repeated observations ascertained, notwithstanding E. H. WEBER contends they are only half as large. Like the pus-globule, they also contain a nucleus, consisting of granules. I have sometimes seen globules of the same form and nature swimming in the saliva; but at other times I have measured them twice and thrice as large. Mixed with water, they quickly swell and are decomposed. Finally, the pus-globules differ from the blood-corpuscles, not only in size, but also in chemical properties, since the envelope of the former is dissolved by both water and acetic acid, whilst that of the latter is dissolved only by the acetic acid." (p. 11.)

The following is the account which GUETERBOCK gives of the chemical nature of the pus-globules, which he obtained from a wound in a horse:—"The globules having been most carefully washed, and had concentrated acetic acid poured over them, were strained. In straining the envelopes of the globules were dissolved. On adding a solution of the ferro-hydro-cyanite of potash, a sediment was produced: the one part of it neutralized by the carbonate of potash was first rendered turbid and then precipitated, whence I conclude that the envelope is to be included among the number of those substances which, named by BERZELIUS albuminous, are precipitated by the ferro-hydro-cyanite of potash. But the granules forming the nuclei of the globules are not dissolved by acids. I cannot yet certainly state whether, like the corpuscles of the blood, they are dissolved by the liquor of caustic potash, though it seems to me very probable that they are; for the liquor of caustic potash (or even the concentrated carbonate of potash) being added, the pus-globules become more transparent, and are less perspicuous, some after a certain time vanish, rudiments of the envelopes and granules being here and there left." (p. 10.)

The pus-globules described by MAYO (*a*) as "occasionally seen in the blood of healthy persons," the only person in whose blood he had not found them being an aged woman of seventy-seven years, though he admits that "nevertheless they differ to a certain extent from the globules which are seen in pus from an ulcerated sore," GULLIVER (*b*) denies being pus-globules at all, and says they are probably the large white globules of the blood spoken of by MAGENDIE and Dr. DAVY.

The following is GERBER's account of the formation of pus, and of the reproductive organization in suppurating wounds:—"A continual oozing of *liquor sanguinis* takes place on the surface of the wound; the coagulating fibrin forms exudation-corpuscles, which are partially disposed in layers on the wounded surface to form the exudation-membrane, and the layers nearest the living surface are converted into cells, which become further and differently organized according to the nature of the tissues to be reproduced. The cytoblasts or exudation-corpuscles most distant from the wounded surface become pus-corpuscles, which, with serum, form true pus, which on the one side covers the seat of organization, separates the so-called granulating surface from external influence, and on the other forms that soft, mild, peculiar medium in which reproduction proceeds from the wounded surfaces towards the middle of the wound, and by which foreign substances are washed out of the wound.

"*Pus.* The exudation-corpuscles lying beyond the living influence of the wounded surface, but exposed to external agency, cannot retain their life for any length of time, and,

---

(*a*) Observationes quædam microscopicæ in partibus animalium pellucidis institutæ de inflammatione. Dissert. inaug. Berol., 1835.

(*b*) Medical Gazette, 1839, 40, p. 128. (*c*) Ib. p 201.

forsaken by the organizing principle, degenerate in their organic formation, and their organic chemical blending; whilst those in contact with the living surfaces of the body, proceed in their further organization: thus, by the death of the former, is given life to the latter (*mors vitæ origo.*)

"Upon the free exudation-corpuscles first appear delicate radiating lines, which divide their periphery into six or eight (rarely more) segments: these lines become more decided, and the capsule appears as if torn, though without any solution of continuity. In some even the nucleus seems inclined to break into from two to four pieces. At the same time the originally reddish-yellow fluid fades, the divided segments of the capsule and the divisions of the nucleus, which were distinctly linear, become rounded into cohering granules, whilst the now perfectly formed pus is of a greenish colour. The true pus-corpuscles thus formed, are still here and there connected together, (the pus-membrane,) like the cells of tessellated epithelium; are specifically heavier than the serum; appear under the microscope somewhat larger than lymph-exudation and blood-corpuscles (from $\frac{1}{300}$ to $\frac{1}{170}$ of a Paris line in diameter;) are of a yellowish colour, and mingled with oil-drops and albuminous granules, with which last they are commonly besprinkled, and which are by many considered as integral parts of the corpuscles, they overlooking the usual large granules which in their connexion with the pus-corpuscles are so attached that the latter at first appear as lenticular, or cake-like quilted cushions. Subsequently the granules separate still more, so that the corpuscles are resolved into their elements; old pus therefore consists for the most part of these more or less isolated granules. * * * The younger the pus, the greater the quantity of fibrin (transition-cytoblasts) and the older it is, the more fat does it generally contain. Thus, in the degeneration of its organization, from its commencement to its perfection, is it remarkably opposed to chyle, in reference to its organic and chemical relations." (pp. 47, 48.)

"*False Pus.* Secreted and exuded fluids very frequently occur in man and beasts, which without closer—that is, microscopic—examination, may be taken for pus, because they look very like it, and chemically often do not differ much from it, and yet are produced in another way, and are of different nature. On the contrary, substances are deposited and thrown out which seem very different from pus, and yet are either true pus, or very nearly allied to it.

"It is the above-described fluid alone, the true or proper, the so-called laudable pus, which is a necessary condition of reproduction: therefore I call it *reproductive pus;* and, as the corpuscles usually consist of seven granules, they may also be called septengranular pus-corpuscles. Previous to their division, these corpuscles always belong to the nucleated corpuscles; they are degenerating cytoblasts. In this constant quality of the true pus-corpuscle is the most certain criterion for distinguishing pus from other more or less similar fluids; and that fluid which contains no such corpuscles, or with them any corpuscles or deposit which do not exist in the pus of healthy wounds, is either not pus, or not pure pus." (pp. 53, 54.)

The following are TRAVERS's views on the constitution of pus:—"Pus, I believe," says he, "to obtain its characters of consistency, opacity, and colour after exudation, and to consist of the superfluous or waste lymph which has been separated during the adhesive stage from the mass of blood held in solution by the serum, being thus a chemical modification of the constituents of the *liquor sanguinis;* in short, the latter fluid deprived of its original character and property of spontaneous coagulation. Pus particles resemble those of lymph seen in the vessels under inflammation, except that they appear broken down and partly dissolved in their texture instead of compact and of less regular figure; and, if when suspended in a drop of fluid, compared with the elastic blood-corpuscle, to which they bear no analogy whatever, utterly inert and devitalized. We never see pus in the blood-vessels but in fatal phlebitis, and, if introduced into the circulation by injection, it is destructive to life. Although, therefore, a clean-wiped granulating surface soon presents a covering of pus, it is exuded as a colourless fluid of a more dense and unctuous consistence than serum. Its appearance is simultaneous with the disappearance of the lymph-particle from the veins, the suppurative action being determined, or, in other words, the separation of the proper lymph-particle put an end to by its sufficient deposit in granulation, and the inflammatory nisus still prevailing from the continuance of the irritation, for no imperfect state can be perpetuated; the superabundant lymph-particle, at no time coloured, along with the permanent fluid or serum of the blood, is strained off through the pencils, forming the terminal loops of the granulation. Thus is obtained the twofold purpose of relief to the loaded capillary circulation, and a bland and homogeneous protecting fluid for the granulation during the period of its growth up to that of final organization. When the rudimental fibrin is no longer needed for the new structure, it is used, as in nature all remnants are, for a new but not less important purpose,—the preservation of that structure. Pus is as necessary to the maintenance of granulation as lymph was to its formation; but a change is necessary to fit it for its new function, and this is provided for by a new arrangement of a new action of the secreting capillaries, and a chemical change, which destroys its vital property and amalgamates the separated lymph-globules with the serum of the blood. The precedence of adhesive to suppurative action is sufficient to render presumable a necessary connexion between the lymph separated during the first process, and afterwards disappearing, and to explain the invariableness of this relation in the order of their appearance. There is no analogy between the effusions of serum or of *liquor sanguinis* incidental to primary wound or injury of any kind and pus, yet the ingredients of the two latter are the same: it is by the combinations of a vital chemistry that their appearance and sensible properties differ, and this we are capable of imitating. If this theory be admitted, it will explain the appearance of pus in the absence of the especial granular structure or distinct pyogenic membrane, as seen upon mucous, serous, and synovial surfaces and canals; and, even in the absence of fibrinous exudation, as in certain modes of inflammation, where the habit of the parts or the character of the inflammation renders them incapable of carrying on the adhesive action, or that action is by violence interrupted. Puriform mucus, muco-purulent secretion, are terms in common use, indicating the transition stage witnessed in these cases; so also the modifications of colour, consistence, and purity are explained, which are conveyed by the terms sanious, flaky, or whey-like, ichorous, &c., and the improvement of the secretion by elaboration from that of fistulæ and sinuses to the 'pus laudabile' of old authors concurrent with the improved vitality of the granulations, meaning a fuller proportion of the lymph-particle to the serum, and *vice versâ*, its degeneration in enfeebled and sinking states of the system. Thus also is explained the effect of inordinate and excessive suppuration to superinduce hectic, from the excessive withdrawment of that ingredient which forms the nutrient and restoring principle of the blood. * * * The conversion of the blood-corpuscle into the pus-corpuscle is a notion altogether gratuitous and unsupported either by appearance or probability; and, to my mind, the above is a theory more reconcilable with all the circumstances attending its origin than that which supposes *de novo* formation of the pus globules. But the wounds of cold-blooded animals not being subjected to the true suppurative process, nor those of mammalia and birds disposed to free suppuration, there appears to be insuperable difficulty in establishing this theory by actual demonstration." (pp. 172, 6.)]

14. The nature of the pus varies considerably according to the nature of the parts in which it is formed, according to the constitution of the person, according to the degree and character of the inflammation; it may be changed by other fluids, mingled with it. We distinguish good cream-like, uniformly consistent, yellowish white, inodorous pus, (*pus bonum et laudabile*, Lat.,) thin, mucous-like, serous, grayish, greenish, brownish, and more or less fetid pus (*sanies*, *ichor*, Lat.; *Jauche*, Germ.) (1). These varieties of pus, as well as the fluid products of inflammation especially, depend merely on the different proportions of the materials composing it. All these products are derived from the blood, and in them are found all the same materials as in the blood, excepting fibrin. Thus is it clear why chemical and microscopical examination cannot ascertain any determinate difference between the products of inflammation and the serum of the blood, the mucus, the serum from dropsy, the yellowish white fluid (*materia puriformis*) poured out from inflamed mucous membranes (2); the thin, lymph-like fluid which exudes from inflamed serous membranes (3) and the various kinds of pus appear to be compounded in the same way. Their difference consists only in the different proportions of the several substances, in their disposition to organization, and in the greater or less advanced degree of plastic activity (4).

The presence of globules in the serum has been long since proved by **Bauer** and **Faraday** (*a*), as also by **Mandt** and others in the various effusions and serosities which occur in the cellular tissue and in the serum of dropsy; but the albumen in pus is in

---

(*a*) See **Home** on the Conversion of Pus into Granulations or New Flesh, in Phil. Trans. 1819, p. 2.

a higher degree of coagulation, is opake, of tolerable consistence, and coagulates less by warmth, and by the concentrated acids. The difference between creamy, consistent, and thin serous pus depends entirely on the different proportions of the fluid and of the pus-globules. **Bonnet**, (as above,) who seems not to know the pus-globules, derives this difference from the greater proportion of the emulsive fat in the former and its smaller proportion in the latter. We may give every kind of pus that semi-transparency, that stringy character, that adherence of its parts which seem especially proper to mucus, if we mix and shake it up with a solution of hydrochlorate of ammonia, whereby the proportion of one of its components is increased. The consistence of pus is to a certain extent influenced by the length of time it has been retained in the body, the absorption of its fluid part thereby occurring, and in suppurating surfaces perhaps also by the influence of the air, as, in the latter case, when the pus is washed off clean, a clear serous fluid is always observed to ooze up. In this manner we may judge of the various tests of pus, for the purpose of distinguishing it from mucus. According to **Grassmeyer** (*a*), if pus be mixed with twelve parts of distilled water and one part of *liquor potassæ*, a viscous transparent jelly capable of being drawn into thread is formed, more quickly or more slowly according to its different composition. According to **Gruithuisen**'s microscopic examinations (*b*), pus exhibits white spherical granules slightly dotted upon the surface, which after some hours fall, and even preserve their round form in pus which has been dried and again moistened. In mucus these granules only appear when it is previously thinned with pure fluid: the granules in mucus are less numerous and dark-coloured. **Fischer** (as above) holds it best, in order to determine the presence of pus and mucus, to mix and shake together the questionable matter with two or three parts of *liquor potassæ* or *liquor ammoniæ caustici*, and then to add hydrochlorate or nitric acid to neutralisation. If it contain pus, there will be produced by the continued addition of the acid a whitish flocculent sediment.

[(1) "Ichor," says **Gerber**, "has very various colours, and is generally more fluid than pus. The ulcer is a wound with a dead surface incapable of throwing out or organizing plastic lymph, bedewed with a depraved serum (*ichor*) destructive of every exudation. This ichor acts injuriously on the ulcer, destroying it and eating into the neighbouring vessels: hence the discharge of small quantities of blood, which is immediately discoloured in the ichor, and so much changed that the *liquor sanguinis* rarely coagulates, save in granules; the blood-corpuscles appear puffed up, corroded superficially, divided into irregular pieces or even shrivelled up. The blood-corpuscles thus altered are denominated *ichor-corpuscles*: they are commonly covered with granules attached to them or partially lying on them; their character is ascertained in the discharge of glanders which principally consists of them." (p. 56.)

(2) "Puriform mucus, secreted in the last stage of catarrhal affections, varies according to the extent of reproduction which the affected mucous membranes require. Should the mucous glands and follicles be altered in a less degree than the cuticle, which after catarrhs is always produced afresh, then the mucus, besides the usual mucous corpuscles and granules, contains, instead of the usual older elements of the epithelium, which are large, squamous, granulated, epithelial cells or cylinders, a large addition of newly-formed small lenticular cells, in which the nuclei are often recognised with difficulty; hence rendering them very like large exudation-corpuscles. Sometimes among these young epithelial cells true pus-corpuscles are observed, when any part of the mucous membrane needs reproduction." (p. 54.)

(3) "In serous exudations," he proceeds, "it is usual to find albuminous granules in albuminous fluids, and, if a great part of the serum be again removed by absorption, the crystals of different salts. * * * After plastic exudations, a yellowish turbid fluid is found in the affected cavities containing fine flocculi of a pale yellow colour: these are partially precipitated upon the walls of the cavity, which appear bestrewed over the whole extent of the exudation." (p. 42.)

The distinguishing characters of true Pus and Ichor have been already mentioned.

(4) This statement of our author, "that chemical and microscopical examination cannot ascertain any determinate difference between the products of inflammation and the serum of the blood," &c. &c., and that "their difference consists only in the different proportions of the several substances," &c. &c., is rather too hasty, as the extracts just quoted from **Gerber** on the subject show that there is a well-marked distinction among them.—J. F. S.]

15. Pus cannot be produced without inflammation; but the latter may

---

(*a*) Abhandlung von dem Eiter und den Mitteln, ihn von allen, ihn ähnlichen Flüssigkeiten zu unterscheiden. Götting., 1790.

(*b*) Naturhistorische Untersuchungen über den Unterschied Zwischen Eiter und Schleim. München, 1809.

exist in so slight a degree as to be scarcely, or even not at all, observable, and, on account of the too slight vital activity of the organ, the low state of the nervous power, and of the plasticity of the blood and the diseased diathesis, a serous thin pus is produced without the appearances of inflammation being manifest. The circumscription also of the pus in a definite cavity proves that inflammation must have been present. Abscesses thus originating are called *Cold Abscesses, Lymph Abscesses* (*kalte Abscesse, Lymph Abscesse, Lymphgeschwülste*, Germ.; *Abcès froid*, Fr.) They are always the consequence of a general cacochemic or dyscracic affection, and arise either spontaneously and commonly in many places at once, or are produced by an external injury.

We may very properly apply with **Walther** the name *Diathesis purulenta* to that general condition of the body which is the ground of these abscesses; but it is improbable that pus can be formed in the blood itself by decomposition within the vessels, and that the blood can be immediately converted into pus. The circumstance of pus having been found in the blood, cannot form a ground for this opinion, as this, if the walls of the veins are not inflamed, intimates merely the absorption of the pus which has been found as well in the lymphatic vessels as in the veins (*a*). The so-called *abscess of congestion*, in which the source of the pus, mostly the carious destruction of bone, is more or less distant from the collection of pus upon the surface of the body, must be distinguished from cold abscess: this, however, will be considered in several places.

16. The commencement of cold abscess usually sets in, without any sensibly perceptible local appearance, with diminution of appetite, general uneasiness, slight fatigue, disturbed sleep, and so on. Next there appears on some part of the surface of the body, (where many patients fancy they have had a sort of prickly sensation,) most commonly between the shoulder-blades, on the chest, on the loins, on the upper part of the thighs, a little, not discoloured, elastic, scarcely fluctuating swelling, which is not painful, and at the utmost gives the patient an obscure sensation of tension and weight. Gradually the swelling enlarges, often to a considerable size, the fluctuation is distinct, and the symptoms of a disturbed assimilation become more marked. After a shorter or longer time, the swelling begins to be painful, the skin covering it reddens, becomes tense, the general appearances mentioned are more decided, febrile action sets in, and the whole countenance of the patient is cachectic. The skin, continuing to thin, at last breaks, and a quantity of thin, pus-like, often completely putrid and stinking, fluid is evacuated, followed by a clear discharge, which, if the neighbouring bone be destroyed, is of an ichorous character. By this great loss of the juices, and by the colliquative sweats and purging, which soon set in, the powers of the patient are speedily broken up.

[The cold abscess here described must be confounded neither with **Hunter's** "collections of matter without inflammation," (p. 390,) which are, as he says, of a scrofulous nature, and very different from that under consideration, nor with "the cold abscess of the surgeons of the Saracen school, the chronic abscess of modern surgeons," mentioned by **Boyer** and **Craigie** (*b*) (pp. 43—163), and caused by *chronic inflammation.*

The true cold abscess, which **Chelius** has here well described, is, I believe, very rare. I have recently had a case of which the following is a brief account:—

Philip Coyne, aged 26, admitted under my care,

August 27th, 1844. He was very irritable, complained of much lassitude and debility, and that he had some difficulty in passing his water, for which about a fortnight ago he had a catheter passed, but had not been since inconvenienced. He did not, upon examination, appear to have any surgical complaint; but, as he had been ill-fed, and suffering

privation for some little time before his admission, I kept him in the house for charity's sake, though I suspected he was feigning illness. He, however, grew worse, had a hot skin, with much perspiration, loss of appetite, pains in his joints; and, again complaining of difficulty in passing his water, which was not, however, caused by any stricture, I considered therefore his case to be medical, and, on

September 3rd. He was transferred to Dr. Burton's care, who treated him with sulphate of quinine and citrate of iron, with a colocynth and calomel pill occasionally. He continued growing worse, and, on

September 10th. I was requested to see him again, when he still complained of difficulty in voiding his urine, and had a largely diffused swelling extending over the whole right inguinal region, without redness, with little pain, but with distinct fluctuation, and extending down behind the right spermatic cord into the scrotum, which was so little protruded that the swelling there was only accidentally discovered. The swelling in the groin, which was only noticed yesterday or the day before, is quite subcutaneous. I made a puncture a little above the middle of Poupart's ligament, and drew off a pint of healthy, sweet-smelling pus, and the swelling in the purse subsided as it flowed. Half a grain of acetate of morphia nightly was ordered, to give him rest, which he much needed.

On the following day he was better, and a mutton chop with porter daily was ordered.

September 13th. There is little discharge from the puncture; but he now points to another subcutaneous abscess without redness and with little pain, beneath the spongy body of the penis, which was opened, and a table spoonful of good pus voided. He complains of much tenderness in the left knee, to which bran poultice was ordered.

September 14th. But little discharge from either opening. Since yesterday a large diffused swelling has presented on the left side of the chest, below the arm-pit, without redness, but tender and with indistinct fluctuation.

September 16th. The abscess just mentioned was opened, and four ounces of good pus discharged. He now points to another diffused swelling, without redness, on the front of the right shoulder, which fluctuates indistinctly. There is but little discharge from the groin. For the last two days he has been taking ammoniated citrate of iron, five grains, with a drachm of compound spirit of ammonia in infusion of quassia thrice a day. I ordered him, in addition, half a pint of port wine, as he sweats very profusely, has a quick, feeble pulse, and is very weak and thirsty.

September 17th. The abscess on the shoulder was punctured, and about an ounce of pus discharged. The sweating still continuing, he was ordered to take of dilute nitric acid ten drops in infusion of roses, thrice a day.

On the following day, being nauseated and a little sick, a draught of peppermint water with a drachm of sulphuric æther was ordered, but it did not do him much good, and, on

September 19th. He was ordered, instead, five minims of dilute hydrocyanic acid in water, a mustard poultice to the region of the stomach, and four ounces of brandy daily, instead of the wine. The abscesses on the shoulder and chest discharge freely; but those below are healed.

September 27th. On the whole, somewhat better; but the discharge is still very profuse. There is now much fluid in the mucous bag behind the insertion of the *m. rectus femoris*, and the knee is very tender: the bran poultice was discontinued, and a blister ordered, with a poultice afterwards.

October 8th. Has not materially improved, and is now attacked with diarrhœa. Ordered fifteen minims of nitro-muriatic acid three times a day.

October 9th. The diarrhœa continues, and is now accompanied with sickness. The acid to be left off, and in its stead fifteen grains of carbonate of potass, with compound tragacanth and acacian gum powder in clove water, with compound spirits of ammonia and tincture of cardamoms, every four hours.

October 21st. On the whole, better; but little discharge from the abscesses; the knee unimproved.

October 28th. Another blister applied to the knee.

November 2nd. The knee considerably swollen and painful; an issue to be put in above and below the joint.

Having got into a very awkward and uneasy posture, his left leg being laid completely on the outside, and not moveable without great pain, I thought it advisable to get the limb on an amesburg, and gradually from day to day to raise it up till on the heel. This was effected in the course of a few days, and rendered him much more comfortable, and the knee diminished in size, as the issues began to discharge. He never, however, rallied, but gradually continued drooping, became very excitable and so weak that he continually passed his motions beneath him. A patient's death near him had very much troubled him during his illness, and, another having died on 22nd December, he again became alarmed, and sunk on the following morning without any other especial cause.

The examination of the body on the third day after death presented the following remarkable and unexpected appearances, as he had never made any complaint, nor had the attendants more than myself noticed any circumstance which could lead to the expectation of the results which occurred.

The body generally was thin, but not much emaciated. The slough on the rump had exposed a large portion of the sacrum. Between the crest of the right ilium and the great trochanter, the soft parts were prominent and fluctuating.

The heart and lungs were perfectly healthy.

All the abdominal viscera were healthy except the liver, which was much enlarged, and extremely pallid, and had degenerated into fat to an extreme degree.

The right *m. iliacus* was raised from the concavity of the ilium; prominent, tense, fluctuating when touched, and the fluctuation communicated to the external prominence between the iliac crest and trochanter. When the muscle was cut into, a large quantity of dirty stinking pus was found filling the iliac pit internally, and communicating through the ischiatic notch, of which the edge had become carious and rough, with a quantity of similar pus extravasated among the gluteal and all the muscles in the neighbourhood of the back of the hip-joint. All the muscles were separated from each other, and had assumed a greenish appearance. In front of the joint there was only a small collection of pus, and the muscles were seemingly healthy. The hip-joint contained a small quantity of dirty purulent fluid; there were slight traces generally of synovial inflammation, specially at the notch, and where the acetabulum was devoid of cartilage. The right ilium was rough and carious on both external and internal surface, and the right sacro-iliac symphysis so extensively destroyed that slight force separated the bones, the surfaces of which were carious.

The left knee-joint: nearly all the articular surfaces deprived of their cartilage, small isolated patches alone remaining, and the exposed surface of the bone being everywhere rough and carious. The crucial ligaments were only partially destroyed.

Neither of the vertebral bodies were affected with disease.—J. F. S.

My friend Dr. Rigby (*a*), in his account of contagious or adynamic puerperal fever, speaks of a peculiar kind of abscess following attacks of that disease, which we saw together in several instances at the General Lying-in Hospital. "Where," says he, "the constitution has borne the brunt of the attack without immediate collapse, and the local mischief been controlled by appropriate means, we find that fresh efforts are made to rid the circulation of the morbid matter with which it is infected. The patient is suddenly seized with severe pain, with heat, redness, and swelling of one of the large joints, presenting all the appearance of arthritic or rheumatic inflammation, and also of certain muscles especially, the supinatores of the arm, the glutæi and gastroenemic. The painful spot soon becomes hard, it is intensely tender, and in two or three days the feeling of fluctuation indicates the formation of an abscess, from which a large quantity of greenish coloured pus mixed with blood and serum, is discharged. The cellular tissue beneath the skin and between the muscles is equally affected, and, if examined when the abscess is just beginning to form, will be found of a dirty brown colour, softened, infiltrated, and here and there condensed with lymph or pus, precisely as in cases of gangrenous erysipelas: the muscular tissue has entirely lost its red colour, and closely resembles the appearance of boiled meat, its structure so softened as to tear easily under the fingers, and interspersed with deposits of immature lymph and purulent fluid, the commencement of what would have been an abscess. Like gangrenous erysipelas, the extent of the abscess does not seem to be limited by a surrounding wall of healthy lymph, as seen in a common phlegmon, but, if deep beneath the surface, it continues to spread in all directions, until nearly the whole limb appears to be implicated in one immense abscess: hence, in those patients who have recovered under these attacks, the limb has frequently been rendered useless, the muscles being atrophied and coherent." (p. 291.) The following observation of the same writer in reference to the contagious nature of these abscesses is extremely important. "That the discharges from a patient under puerperal fever are in the highest degree contagious, we have abundant evidence in the history of lying-in hospitals. The puerperal abscesses are also contagious, and may be communicated to healthy lying-in women, by washing with the same sponge; this fact has been repeatedly proved at the Vienna hospital; but they are equally communicable to women *not pregnant:* on more than one occasion the women engaged in washing the soiled bed linen of the General Lying-in Hospital, have been attacked with abscesses in the fingers or hands, attended with rapidly spreading inflammation of the cellular tissue." (p. 292.)]

17. **Beinl**, **Rust**, and others, consider the nature of the so-called lymph-swelling to be an *extravasation of lymph*, depending on a rupture of the lymph-vessels, or on an unnatural extension of their walls, and they explain the gradual sinking of the powers of the constitution and so on, which occur at the latter period of the disease, and after its bursting, by the continued loss of the lymph (*a*). The observations made on the fluid contained in these swellings (which **Rust** imagined to be only in the earlier period of the disease, transparent and colourless) have shewn that it has more of the properties of pus than of actual lymph, and **Walther** has decidedly proved that the acceptation of the term lymph-swellings in the sense just mentioned is inadmissible; that they must be considered only as abscesses (*lymph-abscesses*) preceded by a stealthy, if not a sensibly perceptible, inflammatory condition, which, however, on account of the too much depressed vital activity, could not produce a plastic consistent pus, but only a secretion of a thin more or less turbid lymphatic fluid. The opinion advanced by **Beinl** that the strongest and most healthy subjects are commonly more subject to this disease than the weakly, that men more than females, and that, without an external injury, a general diseased condition is incapable of producing a lymph-abscess, is incorrect, and has been disproved by **Rust**. How frequently, even by writers on lymph-swellings, cold abscesses and such collections of pus as have formed at distant parts (*congestion-abscess*) (*b*), in consequence of carious destruction of the bones of the vertebral column, have been taken for lymph-swellings, and treated as such, I myself have frequently observed.

Nasse (*c*) describes a case in which a powerful healthy young man, in consequence of an external injury, had a swelling formed on the upper part of the thigh, the contents of which, after opening, perfectly resembled lymph. The pouring out of a clean transparent fluid could not be allayed by any treatment recommended for lymph-swellings, and the patient was exposed to the danger of hectic consumption. The local use of a solution of nitrate of mercury alone brought the lymph-vessels to close. This case (which I myself saw, although only once, in passing through Halle, and convinced myself of the continued outflowing of clear lymph which could be increased by pressure) proves that a collection of lymph in the cellular tissue is possible, as the consequence of an actual tearing of lymph-vessels by external violence, the exudation from which ceases only by obliteration of the torn vessels. Cases of this kind are, however, undoubtedly very rare; to them alone can be applied the term *lymph-swelling* in its proper sense, and therefore the above advanced opinion, "*that the cases commonly spoken of as lymph-swellings are merely modifications of abscesses,*" is rather confirmed than contradicted. This opinion **Langenbeck** (*d*) has also advanced; although he adds, that not unfrequently a swelling is observed on the elbow, which is formed sometimes from a local cause, and sometimes also without, is situated immediately on the olechranon, and contains a clear lymphatic fluid enclosed in a cyst, which deserves the name of lymph-swelling, I must yet deny this assertion, as this swelling at the elbow joint is a dropsy of the mucous bag there situate, and may be compared to the *Hygroma cysticum patellare*. Just as little also can I agree with the opinion of **Ekl** (*e*), who considers the lymph-swelling as an expanded mucous bag in which there is a diseased secretion going on. **Zembsch** (*f*), according to **Kluge**, in order to accommodate the different opinions of writers, distinguishes, 1st, the acute and chronic lymph-swelling, as idiopathic and symptomatic disease; 2nd, the false lymph-swelling or lymphatic abscess.

[A case marked in my note-book, "Collection of synovial fluid within the femoral sheath," which occurred in St. Thomas's Hospital in 1839, seems to me more nearly allied

to the lymph-abscess of this paragraph, of which I was then ignorant than to a collection of synovia, as I thought it perhaps might be. The patient was a healthy country lad, seventeen years old, who three years previously had received a blow on the upper outer part of his left thigh, but seemed to have recovered from its effects. Two months since he noticed a swelling on the outside of the same thigh, about a hand's breadth above the knee-cap, which gradually increased both downwards and upwards, so that at his admission it occupied the outer and fore part of the thigh, from a little above the knee to near the great trochanter, fluctuated distinctly, and was presumed to be an abscess in the outer chamber of the femoral sheath. Fifteen minims of tincture of muriate of iron in mucilage thrice a day were ordered, to excite absorption, which was continued for nearly three weeks without benefit. The thigh then having increased, and fluctuation and swelling having extended about the whole knee, I made, by the direction of my then colleague TRAVERS, whose patient he was, an incision two inches long, about the middle of the outside of the thigh, expecting to evacuate pus or open the femoral sheath; but neither pus nor any other fluid escaped, although I cut into the *m. vastus externus* an inch deep. A tent of lint was left in the wound to keep it open, and hasten the escape of pus if any should make its way through the wound; but none appeared, and in the course of a fortnight the wound had entirely healed. The tincture of iron, which had been continued to this time, was now left off, and two grains of iodide of iron thrice a day, ordered in its stead. A week after the whole thigh was wrapped in mercurial ointment, and swathed in a roller. This treatment was continued for three weeks, but without any diminution in size, or apparent change; fluctuation was still very distinct, and the fingers of one hand being applied, whilst pressure was made with the other hand alternately above, a thrilling fluctuation was felt. It was therefore determined to introduce a grooved needle about the middle of the thigh, and some fluid very similar to synovia escaping by it, an abscess lancet was then, with my colleague's consent, thrust in, making an opening an inch long in the skin, and half its length in the sheath, from which escaped about twenty ounces of the seemingly synovial fluid, which nearly emptied the cavity, leaving a rather moveable lump about the middle of the fore part of the thigh, the character of which I could not make out. The edges of the wound were carefully brought together, the limb rolled, and in four days union had taken place. A week after another free puncture below the former voided a quart of the same fluid as before, and on applying heat it coagulated speedily and almost entirely. The wound was left open, and a roller applied above and below it; but in the course of a week it had again united, and fluid was again secreted, though in smaller quantity. A solid but moveable swelling had at this time also formed to some extent around the wounds. The iodide of iron was then omitted, and, instead, was ordered decoction of sarsaparilla four ounces, with five grains of iodide of potash twice a day; the whole thigh to be enveloped in ointment of iodide of potash. Three weeks after the solidification had increased, and the fluctuation generally was less distinct, and soon after the ointment was given up, and mercurial plaster applied. Two months after, having begun to take the iodide of potash, the thigh had much diminished, there was less fluctuation, the middle outer skin was almost solid, and there is less effusion about the knee. The diminution of size and fluctuation continued, and in about two months he was able to walk about. He continued with us about four months longer, and, when he left the house, the swelling about his knee, although not completely subsided, had so considerably diminished as not to interfere with his walking.—J. F. S.]

18. Ulceration (*Exulceratio*, Lat.; *Verschwärung*, Germ.; *Ulcération*, Fr.) is distinguished from suppuration, in being connected with an actual destruction of parts, (by ulcerative absorption,) and with the secretion of a thin, acrid, fetid, and variously coloured pus-like fluid. It arises either immediately from inflammation, or from a preceding abscess. Its causes are either local injury,—for instance, improper treatment of the abscess which has been opened,—or general disease, as scrofula, syphilis, and so on.

[In considering the subject of ulceration, or "ulcerative inflammation," as he most properly calls it, HUNTER first indicates the economy of the absorbent vessels, and speaks of them in two views: first, as they absorb matter, which is not any part of the machine; secondly, as they absorb the machine itself." The former of these functions is of two kinds, of which the one absorbs external matter, either applied to the skin or received into the alimentary canal; and the other takes up internal matter, as many of the secreted juices, the fat and the earth of bones, &c.; both, however, serve principally to the nourishment of the body as well as to other and even hurtful purposes. The second function, that of "removing parts of the body itself, * * * may be viewed in two lights." The one view presents them as causing "a wasting of the whole machine or part, * * * which I call *interstitial* absorption, because it is removing parts of the body out of the interstices of that part which remains, leaving the part still as a perfect whole. But this mode is often carried further than simply wasting of the part; it is often continued till not a vestige is left, such as the total decay of a testicle." The other view exhibits them as "removing whole parts of the body," and "may be divided into the natural and diseased." Under natural circumstances the absorbents "are to be considered as the modellers of the original construction of the body;" for "no alteration can take place in the original formation of many of the parts, either in the natural growth, or that formation arising from disease, in which the absorbents are not in action, and take not a considerable part: this absorption I shall call *modelling absorption.* * * * Absorption, in consequence of disease, is the power of removing complete parts of the body, and is in its operation somewhat similar to the first of this division or modelling process, but very different in the intention, and therefore in its ultimate effects. This process of removing whole parts in consequence of disease, in some cases, produces effects which are not similar to one another; one of these is a sore or ulcer, and I therefore call it (the absorption) *ulcerative.* In other cases no ulcer is produced, although whole parts are removed; and for this I have not been able to find a term; but both may be denominated *progressive* absorption. * * * * * It may be difficult at first to conceive how a part of the body can be removed by itself; but it is just as difficult to conceive how a body can form itself, which we see daily taking place; * * * but this I may assert, that wherever any solid part of our bodies undergoes a diminution, or is broken in upon, in consequence of any disease, it is the absorbing system which does it. When it becomes necessary that some whole living part should be removed, it is evident that nature, in order to effect this, must not only confer a new activity on the absorbents, but must throw the part to be absorbed into such a state as to yield to this operation. This is the only animal power capable of producing such effects, and, like all other operations of the machine, arises from a stimulus or an irritation; all other methods of destruction being either mechanical or chemical. The first by cutting instruments, as knives, saws, &c.; the second by caustics, metallic salts, &c. The process of ulceration is of the same general nature in all cases; but some of the causes and effects are very different from one another." (pp. 440, 2.) "This process of the removal of parts of the body, either by interstitial or progressive absorption, answers very material purposes in the machine, without which many local diseases could not be removed, and which, if allowed to remain, would destroy the person. It may be called in such cases the natural surgeon. It is by the progressive absorption that matter or pus, and extraneous bodies of all kinds, whether in consequence of or producing inflammation and suppuration, are brought to the external surface; it is by means of this that bones exfoliate; it is this operation which separates sloughs; it is the absorbents which are removing old bones, while the arteries are supplying new ones; and, although in these last cases of bones it arises from disease, yet it is somewhat similar to the modelling process of the system in the natural formation of bone; it is this operation that removes useless parts, as the alveolar processes when the teeth drop out, or when they are removed by art; as also the fangs of the shedding teeth, which allows them to drop off; and it is by these means ulcers are formed. It becomes a substitute in many cases for mortification, which is another mode for the loss of substance; and in such cases it seems to owe its taking place of mortification to a degree of strength or vigour superior to that where mortification takes place; for, although it arises often from weakness, yet it is an action, while mortification is the loss of all action. In many cases it finishes what mortification had begun, by separating the mortified part. These two modes of absorption—the interstitial and the progressive—are often wisely united, or perform their purposes often in the same part which is to be removed; and this may be called the *mixed,* which I believe takes place in most cases, as in that of extraneous bodies of all kinds coming to the skin; also in abscesses, when in soft parts. It is the second kind of interstitial absorption, the progressive and the mixed, that become mostly the object of surgery, although the first of the interstitial sometimes takes place so as to be worthy of attention. This operation of the absorption of whole parts, like many other processes in the animal economy, arising from disease, would often appear to be doing mischief, by destroying parts which are of service, and where no visible good appears to arise from it: * * * but in all cases it must still be referred to some necessary purpose; for, we may depend upon it that those parts have not the power of maintaining their ground, and it becomes a substitute for mortification; and, indeed, in many ulcers we shall see both ulceration and mortification going on; ulceration removing those parts that have power to resist death." (pp. 444, 5.)

As regards "the absorption of whole parts from disease, it would appear," says HUNTER, "that they are capable of being absorbed, from five causes: first, from parts being pressed; secondly, from parts being considerably irritated by irritating substances; thirdly, from parts being weakened; fourthly, from parts being rendered useless; fifthly, from parts becoming dead." (p. 446.)

"The dispositions of the two parts of the living body, which absorb and are absorbed, must," says HUNTER, "be of two kinds respecting the parts; one passive and the other active. The first of these is an irritated state of the part to be absorbed, which renders it unfit to remain under such circumstances; the action excited by this irritation being incompatible with the natural actions and the existence of the parts, whatever these are, therefore become ready for removal, or yield to it with ease. The second is, the absorbents being stimulated to action by such a state of parts, so that both conspire to the same end. When the part to be absorbed is a dead part, as nourishment or extraneous matter of all kinds, then the whole disposition is in the absorbents. (p. 446.) Many parts of our solids are more susceptible of being absorbed, especially by ulceration, than others, even under the same or similar circumstances, while the same part shall vary its susceptibility according to circumstances." (p. 447.)

"Progressive absorption is divisible into two kinds, one without suppuration, and the other with. * * The absorption which does not produce suppuration may take place, either from pressure made by sound parts upon diseased parts, or by diseased upon sound parts." (p. 454.) The absorption attended with suppuration, "which I call *ulceration*," * * * is connected with the formation of pus, being either a consequence of it or producing it, and is that which in all cases constitutes an ulcer. It is this which principally constitutes the progressive absorption. This differs from the foregoing in some circumstances of its operations. It either takes place in consequence of suppuration already begun, and then the pus acts as an extraneous body, capable of producing pressure; or absorption attacks external surfaces from particular irritations or weakness, in which case suppuration, forming an ulcer, must follow, let the cause of that breach or loss of substance be what it may." (p. 456.)

"This process of ulceration or absorption with suppuration, is almost constantly attended by inflammation, but it cannot be called an original inflammation but a consequent, which gave rise to the term 'ulcerative inflammation.' It is always preceded by the adhesive inflammation, and perhaps it is simply this inflammation which attends it." (p. 457.)

"The effect, then, of irritation, as above described, is to produce first the adhesive inflammation in such parts as will readily admit of it, and, if that has not the intended effect, the suppurative takes place, and then the ulceration comes on to lead the matter already formed to the skin if it is confined." (p. 458.) "Any irritation which is so great as to destroy suddenly the natural operations of any one part, and the effect of which is so long continued as to oblige the parts to act for their own relief, produces in some parts, first, the adhesive inflammation; and, if the cause be increased or continue still longer, the suppurative state takes place, and all the other consequences, as ulceration; or, if in the other parts, as secreting surfaces, then the suppurative takes place immediately, and, if too violent, the adhesive will succeed; or, if parts are very much weakened, the ulcerative will immediately succeed the adhesive, and then suppuration will be the consequence. This species of ulceration in general gives considerable pain, which pain is commonly distinguished by the name of soreness; * * * but it does not attend all ulcerations, for there are some of a specific kind, which give little or no pain, such as the scrofula; but, even in this disease, when the ulceration proceeds pretty fast, it gives often considerable pain: therefore the pain may in some degree be proportioned to the quickness of its operation. The greatest pain which in general attends this operation arises from those ulcerations which are formed for the purpose of bringing the matter of an abscess to the skin, as also where ulceration begins upon a surface, or is increasing a sore: whether the increase of pain arises from the ulcerative inflammation singly, or from the adhesive and ulcerative going on together in the same point, is not easily determined; but, in some cases, these three are pretty rapid in their progress, and it is more than probable that the pain arises from all these causes. In those cases where ulceration is employed in separating a dead part, such as sloughing, exfoliation, &c., it is seldom attended with pain: perhaps it may not be easy to assign a cause for this." (p. 459.)

The following are some of Travers's observations on this important subject:—"Ulceration, when it occurs, is consecutive to adhesion and suppuration, in almost all cases; and, although suppuration may now and then pass without ulcerations, in the same manner as adhesion prevents suppuration, yet the frequent case of ulcerative inflammation succeeding to abscess, and the very rare existence of ulceration without pus, constitute the ulcerative, third in order, of the processes of inflammation." (p. 187.)

"Ulcerative absorption never occurs but as an inflammatory process, and the action of the absorbents in this process is therefore exclusively a morbid one, and generally partakes of an increase proportionate and corresponding to the opposed action of morbid secretion." (p. 188.)

"The ulcerative, being a purely vital action of the absorbents proper to the part affected, goes on progressively, either by perforation of the substance, or by an encroachment on the surface, or by undermining and separating parts prepared by disorganization or actual death for being cast off. The texture of the part determines which of these modes of action is employed. The cornea, the cartilage, and bone present the penetrating and circumscribed, foveolous or fossulated ulcer, a pit or chink; the cellular membrane presents the hollowing and undermining process, as in the sinuses and pouches of abscess in cellulous parts and on the margin of indolent ulcers, also between the articular extremities of bones and their cartilages; the spreading or superficial ulceration is best exemplified in the skin. But it is always by the absorbents proper to the inflamed surface that this action is carried on." (p. 190.)

"The ulcerative process stands between the life and death of parts subjected to its action, and administers to either, according to the circumstances of the case; being the instrument of reparation in the suppurative and adhesive inflammation, and of separation and removal of the waste and decayed, in the suppurative and gangrenous. It is the agent of granulation in the former, of sloughing in the latter, case, suppuration being the common link by which these extreme processes are connected. Without granulation ulceration is a wasting process; with it, a repairing one. In like manner, ulceration without suppuration is a devastation without means of control or repair." (pp. 191, 2.)

"An ulcer is a patent and familiar illustration of the pathology, not only of the ulcerative, but of all the processes of inflammation; and, as it is that vital action by which not only the dead are separated from the living, but the living are removed, which have undergone such organic changes, or lost so much of their vital power as to be incapable of resisting absorption, it may be regarded, as before observed, as an agent for life and death, and, if in one case the 'natural surgeon,' (Hunter,) in another the natural destroyer." (p. 196.)]

19. Hardening (*Induratio*, Lat.; *Verhärtung*, Germ.; *Induration*, Fr.) occurs when during inflammation the fluids effused into the cellular tissue (*par.* 4) collect, thicken, and connect the walls of the cells together. Vessels pass into the connecting mass, which becomes organized, and the nutrition of the swelling depends on these vessels. If they are numerous or much expanded, the volume of the part is correspondingly increased, and permanent coagulable lymph is deposited, fatty or even bony masses are produced. If the walls of the cells become firmly united together without further deposit in the swelling, the hardened part sometimes becomes smaller than in the healthy state. The hardness of the indurated part varies according to the quantity of lymph effused in the cellular tissue, according to the structure of the part, according to the course of the previous inflammation, and the duration of the hardening. The skin upon the swelling is commonly not changed: the vessels, however, may be varicose, or the skin itself may be intimately united with the swelling. In this manner are formed, consequent on inflammation, various degenerations, enlargement of parts by hypertrophy, sarcomatous, steatomatous degenerations, and so on.

20. In the hardened parts, if no peculiar irritation exist, the sensibility is

lessened, the circulation seems to proceed but imperfectly, because the nerves are completely enveloped in the plastic mass which connects the several parts, and the more minute vessels are closed: hence the temperature is lower, often sensibly so to the patient himself. Sometimes not the least inconvenience arises from the hardening; but it may run into inflammation, ulceration, and cancer (*a*).

In every part inflammation may run into hardening; but especially in long-continued insidious inflammations; in organs which possess a low degree of vitality, in glands, and those organs in which the very numerous ramifications of vessels are surrounded with dense cellular tissue, in persons of atrabiliary constitution, who have had much mental anxiety, have been subject to scrofula or other diseases which depend upon unnatural mingling of the juices.

21. The transition of Inflammation into *Softening* (*Erweichung*, Germ.) produces changes directly contrary to those caused by hardening, viz., diminished cohesion and consistence—liquescence. It occurs only in long continued dyscratic and cachectic inflammations; it is always connected at the onset with collections of serous, not plastic, matter in the parenchyma of the part, which is therefore sometimes loosened up and thickened; or it consists in actual deliquescence and dissolution of the parts, probably consequent on diminished or changed nervous influence. It may, to a certain extent, be considered as the intermediate condition between ulceration and mortification. The softer and looser the texture of an organ, so much the more readily does softening take place, though it also occurs in hard organs; for example, in the bones: childhood is most subject to it. In many swellings softening precedes and accompanies their giving way.

22. *Mortification* (*Gangræna*, *Sphacelus*, Lat.; *Brand*, Germ.; *Gangrène*, *Sphacèle*, Fr.) is the passage of inflammation into partial death, and the mortified part is subject to the general chemical laws. We usually distinguish with the name of mortification two conditions, viz., the *hot Mortification*, (*Gangræna*, *heissen Brand*, Germ.; *Gangrène chaude* ou *Asphyxie des parties*, Fr.,) in which the living power is not perfectly extinguished, and in which it may be restored to its natural action, (here there is but a certain degree of inflammation,) and the *cold Mortification*, (*Sphacelus*, *kalten Brand*, Germ.; *Gangrène froide*, ou *Sphacèle*, Fr.,) in which the part is actually dead.

[The division here employed by CHELIUS is that proposed by Dr. JOHN THOMSON. TRAVERS objects to the terms mortification and sphacelus on the following ground:—"I do not," says he, "employ the term 'mortification' because it is not technically explicit, and has been vaguely and indiscriminately used. Nor shall I use the term 'sphacelus,' because gangrene is a sufficient synonyme, if the term gangrenous inflammation be accepted, which presents the stages of recoverable and irrecoverable, threatened and devitalized texture. A gangrened part is never restored. By the arrest of gangrenous inflammation, the gangrene may be circumscribed, and, by the supervention of other processes, the dead may be cast off, and the living part repaired with more or less loss of substance. The special use of the term sphacelus has been to designate a state of utter death, in which the part becomes subject to chemical changes, as if severed from the body, and such meaning I affix to the substantive term 'gangrene.'" (p. 208.) Hence it will be observed that TRAVERS's gangrenous inflammation, and his gangrene, are synonymous with CHELIUS's hot mortification, and with his cold mortification.—J. F. S.]

23. Mortification truly consists in the extinction of vascular and nervous activity, in consequence of which partial death ensues. This transition

---

(*a*) WENZEL, Ueber die Induration und das Geschwür in indurirten Theilen. 8vo. Mainz, 1815.

is to be feared in unusually severe and quickly developed inflammations with well marked general symptoms in young powerful subjects, and after the operation of severe injuries; in persons with the general appearance of weakness, if the redness of the inflamed part be bluish, of a dirty yellow, the pain slight, and if it be accompanied with typhus. If the pain quickly increase to a great degree, the inflammatory swelling be hard, dry, and very tense, the heat intolerable, the skin dark red, often brownish, the fever extraordinarily severe, and no appearances ensue which lead to the hope of the inflammation terminating in suppuration, then the signs of incipient exhaustion become manifest. The acute pain becomes dull, aching, stretching; there is still indeed circulation, but its current gets slower and slower, and at last stops altogether. The redness therefore becomes deeper, more dusky, and further extended; the warmth diminishes, the swelling, at first hard and tense, becomes soft, doughy, œdematous, the cuticle rises in blisters, containing a dark-coloured brownish fluid. In this condition the part has not yet lost all its sensibility and warmth; the vital activity may therefore be reawakened and reparation effected. The pulse is small, quick, and loses all fulness and hardness; the patient is depressed, is uneasy, has a languid countenance, cold sweats, dry, dirty tongue, unquenchable thirst, frequently burning hot skin; the features at the same time become pinched, and the urine is thick. When exhaustion of the living activity and fully developed mortification takes place, then the pain ceases entirely, the colour of the part becomes blue, ash gray, or even black, the bone assumes a light white, dirty yellowish, or even black spotted appearance. By the decomposition of the parts still covered with skin, and the evolution of the gases of mortification an emphysematous swelling is produced, the part becomes quite cold, and the general appearances of exhaustion are present in a higher degree, the mortification either spreads further, and death ensues from exhaustion, or on the confines of the slough is produced a bright redness, suppuration, and by the operation of the absorbing vessels a groove, becoming deeper and deeper, by which the slough is thrown off.

[This is Travers's acute gangrene. He observes also, that "if the inflammation occupies a circumscribed space, it is generally consecutive upon, and defined by, the adhesive inflammation; if it appears in several contiguous spots or patches, the whole of the intervening surface, and more or less of the subjacent and surrounding part, partakes of the inflammation and is marked for destruction; if, as often happens, it is of irregular size and shape and the surrounding margin darkly discoloured, tumid and painful to the touch, it is spreading, and rapidly travels along a continuous surface without check, to the destruction of texture, and generally of life. * * * In some rare instances, gangrenous inflammation takes possession of an entire structure, as, for example, hand or foot, or even a limb up to its connexion with the trunk, and beyond it, and the indication is the sudden subsidence of agonizing pain, change of colour to a pale bluish hue, loss of temperature and of sensation, so that the limb looks and feels like gray or clouded marble. I have seen in two cases the upper and lower extremities of the same side so affected in the same patient. The rapid dissolution of the vital principle in such instances, anticipates the march of disorganization; such cases are generally depending on nervous prostration from injury or operation, attended by peculiar circumstances of aggravation, or, yet more frequently, peculiar temperament." (pp. 209, 10.)]

24. The decomposition of the mortified part is accompanied by a peculiar exhalation, different in smell from that occurring in the decomposition of dead bodies, the cause of which seems to depend on the higher temperature to which the mortified part is exposed. The destruction of the mortified part occurs in different ways: 1st, the slough shrivels up, the

cuticle does not separate, the fetid exhalation is less, the pain is sometimes very severe (*Dry Gangrene; Trockner Brand*, Germ.; *Gangrène sèche*, Fr.;) 2nd, the mortified part increases in bulk, the cuticle rises in blisters, which burst and discharge a quantity of stinking ichorous fluid (*Moist Gangrene; Feuchter Brand*, Germ.; *Gangrène humide*, Fr.;) 3rd, all the organic structures without distinction are changed into a glutinous grayish white or ulcerous mass (*Hospital Gangrene; Hospitalbrand*, Germ.; *Pourriture d'hôpital*, Fr.)

[In severe bruises, and occasionally when, after the swelling of a limb consequent on a fracture, the bandages confining splints have become tight and caused much pressure, vesications filled with bluish or bluish-black fluid occur. This often excites alarm, and is mistaken for mortification; but it is of little consequence. It is only requisite to puncture the blisters with a needle, evacuate the fluid, and apply lead wash for a few days, when all soon becomes sound. If the vesications are left unemptied, they often produce inconvenient superficial sores, which heal with the use of zinc ointment.—J. F. S.]

25. Mortification may be produced by all hurts which cause a too high degree of inflammation, obstruction of the circulation, weakness, oppression of the nervous activity, and thereby loss of life of a part; for instance, too irritating treatment of inflammation, checking of the circulation by ligature, too tight bandaging, pressure kept up by unyielding aponeuroses; violent operation of heat and cold, malignant character of the inflammation where in seeming mildness of the symptoms mortification often occurs, of which the cause is generally unknown, but sometimes depends on hurtful matter in the bowels; further, from a great degree of weakness, degeneration of the juices, scurvy, and so on, malignant, putrid fevers, great age, severe bruises and concussions, by which the part is filled with stagnant juices; ligature and ossification of the vessels, (which may without inflammation give rise to mortification,) certain fluids extravasated from their cavities, as urine, bile, feculent matter; bad foul air and contagious influences.

[Brodie (*a*) enumerates sudden loss of blood as sometimes causing mortification, and in proof mentions the case of a man who, whilst very tipsy, one evening, was bled to the extent of three pints, when he became very ill, and the next morning his toes and feet up to the insteps were mortified. They sloughed off, however, and he did well. (p. 635.)

Travers mentions among the causes of mortification "such deep and extensive effusions as compress and annihilate the internal circulation of the part. Thus, I have seen," says he, "a subfascial effusion, following a severe strain of the fore arm, producing a spreading gangrenous inflammation of the extremity to within a hand's breadth of the axilla; and similar cases, of suppuration, between the deep-seated muscles of the thigh, I have known terminate suddenly in gangrenous inflammation of the entire limb to the groin. Injuries of nerves, particularly, are liable to be followed by gangrenous inflammation: of this I have also seen some marked examples. Baron Larrey found reason to attribute the gangrene of the foot following the operation for popliteal aneurism to the nerve having been injured or included in the ligature." (p. 214.)

I recollect many years ago seeing a case of mortification of the whole lower extremity, consequent on a bayonet wound of the femoral artery, in which the death of the limb seemed to result from the slow effusion of blood and gradual distension first of the fasciæ, and subsequently of the skin, which occupied many months. The man was a sailor, and during a homeward voyage from the East Indies dropped a bayonet point into his thigh. The ship being without any surgeon, the captain bandaged the thigh tightly up, and effectually prevented external hæmorrhage for five or six weeks. When he reached home, he was brought to St. Thomas's Hospital, and, on removing the bandage, the wound was found united. The limb was much swollen up to the pelvis;

(*a*) Lectures on Mortification; in London Medical Gazette, 1840–41, vol. i.

but his health had not suffered much. It was thought advisable to wait and see what might be the result. The limb increased in size, the skin gradually became more and more discoloured, and gangrenous in patches; indistinct fluctuation was perceived: he was slowly worn out, and died. On examination, the whole limb was found distended with blood, some of which was coagulated, some fluid, and other mixed with pus. On removing the clots, which were principally about the femoral artery, a spurious aneurism was found, the sac formed by the clot being as large as a hen's egg around the wound made by the bayonet in the artery, which had not closed, and was rather bigger than a crow-quill. On one side of the sac, close to the vessel, was a small aperture, by which blood had continued escaping, probably up to his death, into the surrounding soft parts.

Mortification of a limb, or at least of that part of it in the neighbourhood of an aneurismal sac (which is not uncommon if from any cause the vessel have not been tied at the proper time) in general depends simply on the distension from effusion, which at last bursts the skin.

Mortification occasionally happens in simple fracture, from slow but continued effusion, and without wound of the principal artery or arteries of the limb. I have seen this once in a flour-porter, whose leg was broken by being jammed with a cart-wheel; his constitution speedily took the alarm, and, though incisions were made through the skin to relieve the tension, he gradually became worse, and sunk into hectic, in which state his limb was removed; but he died a few hours after. Although from the first no pulsation could be felt in the tibial arteries, yet the examination after death showed them uninjured and undiminished in size.

Mortification I have also seen in one or two instances occurring from splints having been applied previous to the subsidence of the swelling after fracture, and not proportionally loosened as the swelling increased.

The two following are cases of mortification, resulting, the first from simple continued fever, and the second probably after scarlet fever:—

Case 1.—J. J., forty-eight years of age, a hatter by occupation, of intemperate habits, is now—

Aug. 1. Slowly recovering from an attack of fever which commenced seven weeks since. A sore on the inner ankle of the left leg, which he has had for eighteen months, about five weeks since became sloughy, and the surrounding skin was attacked with gangrene, which continued spreading till it has attained its present size, that of the hand. As yet there is not any line of demarcation, and the wound is very painful though cleaning. He is much emaciated, very weak, without appetite, cannot rest, his pulse extremely quick and almost imperceptible, (this may perhaps arise from exhaustion in bringing him to the hospital,) the countenance sunk and pallid, surface warm, but occasionally bathed in profuse sweats, tongue clean. I ordered for him five grains of carbonate of ammonia, with ten minims of tincture of hyoscyamus every six hours, six ounces of brandy and a pint of beef tea, with arrow-root daily. To the wound, chlorate of soda lotion and linseed-meal poultice.

Aug. 2. Better, but without sleep. Twenty minims of tincture of opium at night.

Aug. 4. Is improving; the wound is free from pain, and two or three granulations are seen in its centre; the slough has rather increased. An abscess which has formed on the outside of the knee was opened, and a teaspoonful of thin but otherwise healthy pus discharged; pulse improved; he complains of sore throat, with difficulty in swallowing, and disposition to retch, but he takes plenty of fluid though he cannot manage solid food. As he wished for some porter, a pint daily was ordered. The mixture discontinued; but twenty minims of tincture of opium in camphor mixture directed to be taken at night.

Aug. 9. Is improving, and yesterday began taking a mutton chop. The slough has cleaned from the wound, leaving a sore surface which, occupying nearly two-thirds of the back and inner part of the leg, is now beginning to granulate. As the pus seemed disposed to bag on the outside of the instep, in consequence of the limb lying on its outside, the skin was cut through to prevent this, and a small abscess below the tubercle of the shin-bone opened.

Aug. 15. Improving, and desiring more nourishment. Two pints of beef tea daily.

Aug. 22. The wound almost completely cleaned, but the granulations are flabby and pale. An abscess which has formed at the upper part of the thigh was opened, and about an ounce of good pus evacuated. He wishes to have more porter, which was therefore increased to two pints, and the brandy diminished to four ounces. Nitric acid wash to be applied to the wound.

Sept. 2. During the last two or three days the granulations have been receding, and have now exposed a large portion of the shin-bone, which is apparently dead; a considerable part of the Achilles' tendon has become gangrenous. The drain upon his constitution has lately been much increased, and it is now a question whether amputation be not necessary, and also whether he is in a condition to bear it.

Sept. 6. The wound is more healthy, and the gangrene seems to have stopped. Another abscess, merely superficial, which had formed about the middle of the thigh, burst yesterday.

Sept. 11. Sleeps well and feeds well, but does not get flesh; there has been a slight increase of sloughing on the instep, but it is now cleaning. The discharge from all the wounds is very free, and the granulations rather more florid.

Sept. 13. Appetite failing. An abscess on the inside of the calf, which seems to extend among the muscles, opened, and about three ounces of pus discharged.

Sept. 20. Still declining, and during the last two or three days sloughing has recurred. Amputation was therefore proposed, but he would not consent.

Sept. 24, 9 A. M. Much exhausted; pulse quick and scarcely perceptible; countenance pallid; voice weak; the sore quite bleached. I ordered him brandy and egg, as much as he could be induced to take, which somewhat revived him, and afterwards he took some wine. At 1 A.M. bleeding occurred, probably from the saphenous vein, as it traversed the wound; it was, however, easily checked, and did not recur. He continued gradually sinking, and, on

Sept. 25, 2 P.M. He died.

CASE 2.—E. U., twenty-seven months old, of scrofulous habit, has been weaned about thirteen months, and, like the children of the poor generally, since fed on bread and butter, with tea. She has been always healthy till about sixteen days since, when the whole surface of the body became so scarlet that it was supposed to have scarlet fever. Two days after she was observed to point continually to the left side of her chest, and on examination there was found on the axillary margin of the pectoral muscle a dark-coloured swelling, in circumference about the size of a small tea-cup. Soon after the redness of the body subsided; but her belly was enlarged and the legs swollen. It would, therefore, seem probable that the previous disease was scarlet fever.

At the present time (*Sept.* 8) there is a well-formed brown slough, surrounded with a dusky-red elevated edge of skin with similar inflammation extending about half-way down the left arm, also upon the neck and back, reaching as far as the right shoulder. The cellular tissue of the right arm-pit hard, inelastic, and painful, as if another slough were likely to take place. A layer of the slough was removed, and strong nitric acid applied with a feather; after which it was covered with nitric acid lotion and linseed-meal poultice. To the back of the neck a linseed poultice with acetate of lead wash was applied. Five grains of extract of bark every four hours, and an ounce of gin every six hours, were given in arrow-root.

Sept. 10. The sloughy sore is cleaning; but the hardness on the right shoulder has increased; the inflammatory blush has spread considerably, and now covers all the chest and the belly as far as the navel, extending down on either side towards the flanks. On the left arm it reaches below the elbow, and on the right half down the upper arm. The cellular tissue on the loins is œdematous. As the gin is rejected, a couple of tea-spoonfuls of port wine with syrup was ordered frequently during the day, but not to exceed four ounces. Two grains of mercury with chalk, and four grains of rhubarb with as much carbonate of soda, nightly, were prescribed.

Sept. 11. Has had three dark-coloured stools, but her appearance not improved. She continued sinking, and about 4 P.M. died.

No opportunity of examining her body occurred.—J. F. S.]

26. The mortification dependent on very low vital activity which generally attacks the feet and more rarely the hands of old people (*Senile Gangrene, Gangræna senilis,* Lat.) must be considered as peculiar. Under this name, however, conditions have been classed together which, at least in reference to their origin, must be distinguished from each other.

27. In persons who in every respect have lived irregularly, and whose living powers are in a great degree exhausted, who have suffered much trouble, and had irregular gout, specially in the feet, an erysipelatous inflammation with dusky redness and severe pain arises after any injury,

viz., after the violent action of frost, contusion or wound of the toes in cutting the nails or corns. This redness spreads more or less, forms blackish bladders on one or more toes; the cuticle separates, and the exposed true skin exhibits a deep dusky redness. The inflammation usually spreads still further, but slowly; attacks one after another all the toes; and usually in its progress the part next to be attacked swells, and is excoriated. Sometimes it is circumscribed, in which case the toes dry like mummies and fall off. Most commonly the mortification spreads over the ankle-joint, and in its further extension death ensues from exhaustion: it may, however, be confined to different parts, and nature may bring about a separation of the mortified part. The pain is usually severe, and is soon accompanied with fever.

28. In this kind of mortification the depressed condition of the vascular and nervous activity must be considered as the actual cause why in the operation of the above-mentioned hurts, the inflammation quickly passes into mortification and drying up, mostly of the parts farthest distant from the centre of circulation. This mortification exhibits some similarity to the dry mortification of frostbite.

29. The other form of this mortification happens without any previous local injury, but after general indisposition of more or less duration, such as depression of spirits, listlessness, unquiet sleep, debility, sparing, high-coloured urine, laborious breathing, palpitations of the heart, anxiety, pain at the pit of the stomach, small, weak, irregular, or intermitting pulse, shiverings, or constant internal cold. In the part in which subsequently the gangrenous drying appears, pains of varying severity come on, sometimes accompanied with cramps in the extremities: these go on for weeks, and even for many months, before the local destruction is observed. Or the patient has a sensation of cold in his extremities, a recurring sensation of being asleep for a longer or shorter time, insensibility to external irritation of the fingers and toes, entire loss of motion. Without any local cause the patient observes on his toe or on his finger a black, blackish-brown or brownish (never dusky-red according to BALLING) colour, without any tense swelling. The part dries, the cuticle loosens itself, the part becomes quite black and lifeless. The prognosis of the disease varies: often is only one toe or one joint thrown off, or it attacks all the toes, confines itself to the foot, or spreads up to the knee. The process of separation is connected, as in common mortification, with a bounding red line and slight suppuration. This kind of mortification may occur on various parts at the same time. The same appearances take place in children: the extremity becomes black-blue, its temperature diminishes, and it seems to be completely atrophied. In one case BALLING observed a blackish-yellow colour and dried skin. Sometimes a lower degree occurs, and then from the first the extremities are livid and œdematous.

[This form of mortification is TRAVERS's chronic gangrene, which he says "is generally an idiopathic affection, *i. e.* independent of injury, and which he has never known to be traumatic. * * * The main distinction between this and acute gangrene is, that from the first the part thus affected losing its temperature and colour becomes dry, tough, and shrunken, instead of moist, soft, and swollen, and takes on a yellow or blackish-brown appearance, nearly resembling that of a mummy." (p. 211.)]

30. This form of mortification or mummy-like drying up is always the consequence of an exhaustion in the peripheral parts of the vascular and nervous systems. This condition occurs most commonly in old, decrepid

persons living anxiously and in want of food; more frequently in men than in women; in persons who have prematurely exhausted themselves by excessive debauchery; in those subject to the gout, in whom, perhaps, the ossification of the arteries, so often observed in this kind of mortification, seems to be connected: this disease, however, may occur in every age if the above conditions are present. This kind of mortification may arise suddenly, and without any previous inflammatory symptoms, by metastasis during the course of malignant fever (1). In children born with blue, cold atrophied extremities, in whom the circulation does not proceed properly it is often noticed. The closing up of the blood vessels is, according to Balling (*a*), constantly observed (2). Organic changes in the heart and aorta are also invariably present (3).

(1) I have seen one case in a man thirty-five years old, in whom during the progress of abdominal typhus, the right foot up to the middle of the leg, became suddenly pale, icy cold, senseless and motionless, shrivelled, subsequently quite black, and the dry gangrene reached to the upper third of the leg, where it stopped.

(2) The closing up of the arteries *is always present in dry gangrene*, as was observed in former times; it may be also in certain cases the special cause of the mortification, and consequence of the inflammation of the arteries, (*arteritis*,) or of the capillary vessels, first described by Dupuytren (*b*). It cannot, however, be considered as the general and constant cause; for, in many cases, there is not a single previous appearance indicating inflammation of the arteries, and their closure is caused by the mortification, and consequent to it. Compare also Hecker (*c*).

(3) I have observed a case of dry gangrene in a man about forty years old, which extended up to the middle of the leg, where it stopped, and the part separated. There had existed for a long time undoubted symptoms of organic disease of the heart.

[Brodie (*d*) mentions a case of mortification of the leg up to the middle of the thigh, which commenced with a sense of pricking numbness and weight, and on the following day the limb had mortified; "no vesications formed on the foot; it was not swollen, and no part became putrid except just a little in the middle of the thigh, where was a great mass of soft parts. The limb dried, the skin assuming a brownish colour, being at the same time hard and semi-transparent, so that the white tendons could be seen shining through it. It was in fact what has been called a case of dry gangrene." The patient's powers failed, and he died at the end of six weeks. Upon examination, Brodie "found marks of inflammation everywhere around the principal artery and vein of the limb. From the bifurcation of the large trunk down to the middle of the thigh, the artery was obliterated, being completely filled with coagulated lymph, evidently effused from inflammation; closely adhering to the inner surface, but with some admixture of red coagulum. The vein was filled with lymph and obliterated in the same manner as the artery. There had been inflammation of the sheath of the vessels, in consequence of which the artery and the vein adhered closely to each other and to the surrounding parts. I suppose that the nature of the case is plain enough: there had been inflammation of the artery and the vein, and the obliteration of the artery was to so great an extent as to cut off the supply of blood, not only through the trunk, but through the anastomosing branches." (p. 635.) Brodie also points out the cause of the distinction between dry and moist gangrene:—"If mortification be the result of inflammation or of venous obstruction, there is always an effusion of serum before the parts completely dry, in the form of vesication of the skin and œdema of the cellular membrane; and then, when the parts die, being infiltrated with serum, they readily become putrid. But here (in inflammation of the arteries) the blood is prevented from entering the limb, so that there can be neither vesication nor effusion of serum into the cellular membrane, and the dead parts dry readily from the absence of moisture." * * * Gangrene from arterial inflammation is comparatively a rare disease, and may occur at any period of life; whereas the gangrene of old age arises, as repeated dissections have enabled me to determine, entirely from other causes." (p. 636.) From this latter observation it will be perceived that Brodie does not agree either with Cruvelhier (*e*), who

(*d*) As above.

(*e*) Maladies des Artères; in Dictionnaire de Médecine et de Chirurgie Pratiques, vol. iii. p. 394.

says, that "coagulation of the blood is, after his observations, the essential character of incipient *arteritis*," (p. 394;) or with DUPUYTREN (a), who says that, in such cases, "Pathological anatomy always shows the existence of inflammation of the arterial tunics. This phlogosis may doubtless occur in arteries which are unhealthy, indurated, ossified, as often met with in old persons; but it appears also in the arteries of young people without trace of these disorders. In a word, it may coincide with the calcareous incrustation of the vessels and with age, or it may be independent of both conditions." (p. 484.)

I have seen but a single case of *arteritis*, which happened in a young man of twenty years. It differed from BRODIE's case in not having exhibited the slightest appearance of gangrene, and, on dissection, the brachial artery was found partially obliterated, and shrivelled to a narrow cord, precisely as if a ligature had been applied upon the subclavian artery. Although, in this case, the pulse at the wrist ceased suddenly, yet the circulation was undoubtedly carried on by the collateral circulation, and thus gangrene prevented. I shall refer to this case again when considering inflammation of the coats of arteries. (p. 74.)—J. F. S.

A most remarkable case is given by SOLLY (b) of gangrene, which commenced in a boy about three years old, and, gradually spreading from limb to limb, destroyed him when four years old. In four months from its commencement the disease had amputated the left foot above the ankle, as also two toes of the right foot, and upon the right calf and knee were hard gangrenous spots. The right fore arm was cut off through the middle of the ulna, and the radius had dislocated itself from the elbow joint; the whole of the left fore arm and part of the upper arm were gangrenous. There was a dusky spot on the nose upon the scar left by a gangrenous spot which had formed previously, and separated. In the sixth month the left leg, which had become quite gangrenous, was thrown off below the knee, and the toes of the right foot had also sloughed off. The right ulna had come off at the elbow-joint, and the left arm had amputated itself through the middle of the upper arm. The gangrene on the nose had reappeared, but been checked. For a short time there seemed a little rest in the gangrenous process; but it was again set up, and by the twelfth month the left leg had become gangrenous to the middle of the thigh, and all the soft parts separated, leaving the bone bare. The right leg had mortified to the middle of the calf, and the right foot separated above the ankle. The stumps of both arms had become gangrenous up to the shoulders. In the beginning of the following month the child died. Careful examination of the body did not show any organic disease; but the child had become much emaciated. The stumps of the arms had nearly healed; but in the lower limbs the bones protruded, and the cure was less perfect.]

31. Mortification from continued pressure, or from constant lying upon one part (*gangræna ex decubitu*) occurs more readily, the weaker the patient, and the less cleanly and smooth the bed is. On those places where the pressure acts, most commonly, therefore, on the sacrum and coccyx, the great trochanters, the shoulder-blades, elbows, heels, and so on, a limited redness appears, with pain more or less severe, the skin is destroyed by ulcerative absorption, and a dry slough is formed, which is dissolved in the suppuration set up around it. Should the pressure continue, and the general weakness be great, (for example, in typhus fever,) the destruction spreads very extensively, and in many cases death is thereby accelerated or even caused.

32. A special mention is required of that mortification which, in certain localities, in very wet and humid years, when the rye is infected with the blight, called "cockspur," occurs in the lower extremities, with a constant sensation of itching, great burning, and a darting pain, sometimes with redness and swelling, consequent on which the parts become cold, senseless, black, mummy-like, and shrivelled up. In rare cases this disease has been also observed in the upper extremities. During the course of the disease general symptoms, fever, delirium, and so on frequently arise. Oftentimes the mortification becomes defined and the part is thrown off, and often it spreads up to the hip-joint.

(a) Leçons Orales de Clinique Chirurgicale, vol. iv.

(b) Med.-Chir. Trans., vol. xxii. p. 253, 1839; vol. xxiii. p. 237, 1840.

[A very interesting account of mortification from the use of rye-bread affected with cockspur (*secale cornutum*, Lat.; *Mutterkorn*, Germ.; *ergot*, Fr.) has been given by **Thomson**. "This is," says he, "a species of mortification which has not been observed in this country; but it is well known and has been frequently observed in different parts of the continent of Europe, particularly in France, where it has been repeatedly known to prevail in some districts as an endemial disease." (p. 538.) **Pereira** (*a*) supposes this disease is referred to in a passage he quotes from **Sigebert**. "1089, a pestilent year, especially in the western parts of Lorraine, where many persons became putrid, in consequence of their inward parts being consumed by St. Anthony's fire. Their limbs were rotten and became black coal. They either perished miserably or, deprived of their hands and feet, were reserved for a more miserable life." He also refers to a similar passage in **Bayle**, with the addition, that "the bread which was eaten at this period was remarkable for its deep violet colour." (part ii. p. 595.) **Thomson** says, the disease was first noticed by **Dodard** in 1676; then by **Saviard** (*b*), in 1694; and by **Noel** (*c*), in 1710, in the Hôtel Dieu at Orleans, of which they were both surgeons; in 1709 and 1716 it appeared in Switzerland, and was described by **Langius** (*d*); **Quassoud**, and also **Bossau**, described it on its appearance in Dauphiny in 1709. **Duhamel** (*e*) mentions that in 1748 not more than four or five persons out of a hundred and twenty who had been attacked escaped with life. **Elliotson** some years since had, in St. Thomas's Hospital, a case of gangrene of the leg after using ergot; but he informs me that on examination after death the arteries of the limb were found ossified: it might, however, have been the immediate exciting cause of the disease.

Although there was no doubt that in man the cockspur would produce gangrene, **Model** (*f*), a Russian, made experiments which led him to conclude that rye, damaged with cockspur, had not the power of exciting gangrene in brutes. This remarkable statement induced the Royal Society of Medicine at Paris to employ **Tessier** (*g*) to visit those countries where the disease was prevalent, and to institute experiments to determine the fact, and the result showed that brutes eating it were destroyed by gangrene; but, in all the animals upon which it was tried a certain quantity, varying according to circumstances, of the cockspur was required to be taken, in order to produce the effect; and, as **Thomson** says, "this afforded also a simple explanation of the fact, that persons might live for a considerable time upon rye affected with cockspur without suffering any sensible injury from its use." (p. 547.) **Pereira** states, however, that "there are not wanting cases apparently showing that spurred rye has no injurious action on animals. The most remarkable and striking are those related by **Block**. In 1811 twenty sheep ate together nine pounds of it daily for four weeks without any ill effects. In another instance twenty sheep consumed thirteen pounds and a half daily for two months without injury. Thirty cows took together twenty-seven pounds daily for three months with impunity, and two fat cows took, in addition, nine pounds of ergot daily, with no other obvious effect than that their milk gave a bad caseous cream, which did not yield good butter. These statements furnish another proof to the toxicologist that the ruminants suffer less from vegetable poisons than other mammals." (p. 600.)

A very curious history of a mother and five children, some of whom lost one and others both legs, as related by Dr. C. **Woolaston** (*h*), seems to have originated in the use of discoloured clog-wheat.

Ergotism, as the disease produced by the cockspurred wheat or rye is called by the French, is of two kinds, the *convulsive* and the *gangrenous*; with the latter only have we to do here; it sets in with formication, or the feeling of insects creeping over the skin, voracious appetite, coldness and insensibility of the extremities, followed with gangrene.]

[32.* Here must also be mentioned that mortification of the cheek which has been called *Noma* by **Vogel**. It is fortunately not frequent, as it is a horrible and generally fatal disease. With a single exception, of the half dozen cases I have seen, all were children under four or three years old; some idiopathic, and others originating in a sloughing of the mucous membrane of the mouth, under the careless use of mercurials; and, though

generally in unhealthy subjects, yet the disease also occurred in robust, well-fed children. In its idiopathic form it has been well described, by Drs. **Evanson** and **Maunsell** (*a*), as follows:—"A particular form of gangrene of the mouth, without any preceding inflammation, occasionally attacks infants, especially such as are feeble at birth or broken down by disease. An œdematous circumscribed swelling appears on the cheek, with a central point, more or less hard, over which occurs a dark-red spot. This spot may appear on the inside or outside of the cheek; and the skin over the œdematous part is characterized by an oily appearance. An eschar forms from within outwards on the central point, and the soft parts mortify, often extensively, down to the bone, so that the parietes of the cheeks and gums are destroyed, falling off in shreds, mixed with a dark sanguineous fluid, and accompanied by a very fetid odour." (p. 214.) In neither of my cases, excepting the adult, did I witness the beginning of the disease; but gangrene to a greater or less extent of one cheek, involving generally the corresponding half of the upper lip, existed when the children were brought to me; the surrounding parts were tumid, hard, and of dull yellow-white hue, very similar to the characteristic colour of the countenance of patients under malignant disease. I have little doubt that the mortification of the mouth and fauces after measles, mentioned by **Huxham** (*b*), as well as those referred to by **Marshall Hall** (*c*), and by him stated to have happened after previous disorder of the digestive organs, typhus fever, or some inflammatory disease, are of precisely the same character as those resulting from mercurial influence. The little patient, if not already in a typhoid state, soon falls into it, rapidly sinks as the gangrene spreads, and quickly dies; often, indeed, before the least attempt at separation of the slough has been made. Usually three or four days are sufficient to destroy life; but, in one instance, I recollect a child of two years old having lived for a fortnight, and the greater part of the gangrenous cheek had separated, leaving one side of the cavity of the mouth completely exposed. I fully agree with **Evanson** and **Maunsell**, that "no disease can be more frightful or formidable than sloughing of the mouth in children. Recovery seems impossible, when once the disease has set severely in, the child sinking beneath the constitutional disturbance, independent of the local ravages of the disorder, which, however, are often such as to render recovery not to be desired, so frightful is the deformity necessarily entailed." (p. 215.)

The term *Cancrum oris* has been loosely applied both to the disease just mentioned, and also to another form of mortification commencing with ulceration, generally first in the gums, and thence spreading to the lips and cheeks. This second form alone is considered by Dr. **Cumming** (*d*) to be *cancrum*. He describes it as being either acute or chronic, and, if the former, more liable to be accompanied with sloughing, but the ulcerative process predominates, and by it, principally, the destruction is effected. It does not, according to this writer, attack children at the breast, nor under eighteen months, but occurs between twenty months and seven years.

The following is a short account of the case of noma in the adult alluded to above:—

R. I., a gunmaker by trade, was admitted under my care—

(*d*) Dublin Hospital Reports, vol. iv. p. 18.

August 1, 1844. Having two superficial sores on the glans penis and a superficial sore on the back of the pharynx, sloughy and painful, so much so as to prevent him sleeping at night. He is much out of health; quick, irritable pulse; hot, dry skin and foul tongue. He has also a very small sore, scarcely perceptible, and covered with a dry scab, on the face near the nostril. He was not seen till

August 2. Probably from not having come in, and then ordered *pulv. rhei c. hydr.* ℈j. *stat; sod. carb. gr.* xv. *acid. citr. gr.* x. *tinct. hyoscyam.* ʒss. *aq. distill.* ℥jss. 6*tis horis; garg. acid. nitr.*

August 6. The mixture omitted, and in its stead ordered *acid. nitr.* ♏ iij. *inf. rosar.* ℥jss. *ter die. pulv. ipec. c. gr.* x. On

August 9. Very restless, scarcely sleeps at all; and is so feeble that he can hardly answer the questions put to him. Ordered a glass of wine and a pint of porter daily, and *morph. mur. gr.* ⅛. On

August 15. Has slept better since taking the morphia. The crust under the right nostril has increased in size and is accompanied with swelling of the surrounding parts, which are of a purplish colour.

August 17. Is much worse; the lip immensely swollen and livid, but not giving any discharge; face so much disfigured that he can scarcely be recognised. The sore in the throat much worse; bowels confined. ℞ *pulv. rhei. c. hydr. gr.* xv. *stat; vin. rubr.* ℥vj. *quotid.*

August 20. Is very feeble and unable to speak. The slough has now extended around the mouth from the nose to the chin, including the lips and part of both cheeks. The sore in the throat has become very sloughy. Four ounces of brandy, three eggs and some arrow-root were ordered; but he was not able to take much, and gradually sunk till

11. *p.m.* When he died. No discharge at all had occurred from the lip. No examination of the body was made.—J. F. S.]

33. Mortification occurs as a consequence of contagious influence, either by the contagious matter producing at first an inflammation which terminates in mortification, (*malignant pustule*,) or by coming in contact with the surface of a wound or sore, whereby the destruction of it is brought about (*hospital gangrene*.)

34. The ***Malignant Pustule*** (***Pustula maligna***, Lat.; ***bösartige Pustel***, Germ.; ***Pustule maligne***, Fr.) is always consequent on local contagion. On the place which the contagious matter has touched, there appears in a short time prickling and a red point, which is scarcely raised above the skin. The cuticle rises in a blackish vesicle, which is soon converted into a slough surrounded by a whitish or violet edge and œdematous swelling, and spreads quickly in all directions. From the very onset there is perceived in the pustule a hard nucleus, which enlarges both inwards and outwards, or only spreads laterally. Notwithstanding the decided swelling, the patient complains rather of tension than of actual pain. Sooner or later it is accompanied with fever, pain in the region of the stomach, nausea, vomiting, high delirium, fainting, and so on. The pulse is small, irregular, and, if left to itself, the disease generally runs on to death, which in malignant cases follows very speedily. It is rarely that the slough comes away, and that the cure is effected by the mere powers of nature, or that in the course of this disease the general symptoms already mentioned do not appear. If several pustules are formed at the same time, especially on the neck or face, the disease is more dangerous. The swelling is often here so great that symptoms of suffocation and congestion of the brain are produced. In women the disease proceeds more quickly than in men. At the onset a stop may usually be put to this disease; the danger increases in its subsequent course. It differs from carbuncle (*par.* 118.)

The contagion develops itself in beasts which are affected with contagious carbuncle (*Milzbrand*;) it may be communicated whilst the animal is alive, or it may take place during the preparation of wool, hides, and so on. The malignant pustule is therefore most commonly observed in butchers, tanners, woolbeaters, shepherds, and especially on those parts of the body usually uncovered. In wet districts, in moist autumns, the disease is most common. The contagion preserves its power for a long period. Actual contact is not always necessary to produce infection. The use of the flesh of such beasts sometimes does not produce any, but at other times very dangerous, symptoms. This disease seems not to be communicable from one man to another, at least the facts relating thereto are not perfectly indisputable; it is also doubtful whether the general symptoms can be produced by the assumption of this contagion into the body, without the malignant pustule on the skin.

Precisely similar phenomena have been observed in reference to the transference of the poison of glanders from horses; upon which see the article entitled

Elliotson, John, M.D., On the Glanders in the Human Subject, in Med.-Chir. Trans., vol. xvi. p. 171. Additional Facts respecting Glanders in the Human Subject, ib., vol. xviii. p. 201.

[Elliotson has given a very excellent account of "The Glanders in the Human Subject," in which the communication of the disease from the horse to the patient is distinctly made out. He mentions six cases; the first three he considers *acute*, two of which occurred in St. Thomas's Hospital, and both died very speedily after having been attacked; the third occurred in a dragoon regiment in Ireland; the fourth was a veterinary surgeon at Clapham; both died. Two cases, which he calls *chronic*, extracted from Travers's book "On Constitutional Irritation," one of which died, and the other long suffered from a broken-up constitution. He also refers to the cases mentioned in Rust and Omodei's journals. In a subsequent paper he gives "Additional Facts respecting Glanders in the Human Subject," in which he mentions another case that occurred in St. Thomas's Hospital, which also died.

I have to thank my friend Lawrence for the following observations of the cases of malignant pustule which have come under his care, and which, on account of their rarity I gladly avail myself of the opportunity to introduce on the present occasions. He says:—

"I have had under my care, in St. Bartholomew's Hospital, three cases of malignant pustule, in neither of which, however, did I see *either pustule or vesicle*; of the first and most remarkable, the following is the report from the Lancet of 1825-6, p. 127, in which it is described as "*A singular case of Erysipelatous Inflammation of the lower Eyelid, terminating in gangrene in the short space of six hours.*"

John Barker, aged 52 years, currier, stout and robust, came to the Ophthalmic Institution, and, immediately after, in consequence of the nature of his ailment, by Mr. LAWRENCE's advice, was sent into St. Bartholomew's Hospital.

Feb. 18, 1826. He stated, that the day before yesterday, whilst at his usual employment, he struck his right eye with a skin of leather, which at the time caused him great pain and uneasiness. At this time there is an erysipelatous inflammation extending around the organ, but more especially on the lower lid and adjacent portion of the cheek, in the centre of which there is a hard and indurated lump, more prominent than the rest, feeling like carbuncle. It has a very livid hue, and may be said to have gone into a state of gangrene. Since his admission into the hospital, he has not complained of any particular pain in the part, nor is the constitution apparently much affected; the tongue is but slightly loaded; the pulse feeble. Mr. LAWRENCE made an incision through this hard and indurated portion, when a little dark blood escaped. The globe of the eye not in the least affected. Two grains of sulphate of quinine to be taken every six hours, and six ounces of port wine, daily.

Feb. 22. The pulse having been quickened last night, the wine has been in consequence discontinued; and a dose of house medicine given this morning.

The tumefaction above the lid still continues, and there is now a distinct line of demarcation around the gangrenous spot before alluded to. The whole of the inflamed skin, has a peculiar, hard, brawny feel, very similar to carbuncular inflammation. Mr. LAWRENCE stated, that when the man came to the infirmary, there was no unusual vascularity of the eye; a slight serous effusion only had taken place beneath the conjunctiva palpebræ. A slight puffiness is observable about the under lid of the corresponding eye, but there is no redness. Pulse soft and compressible; bowels open and tongue moist. The quinine to be continued; the wine resumed, but omitted at night if necessary.

Feb. 25. Has passed a good night and the condition of the parts is improved. The wine and bark, being too stimulating, are both discontinued. A more scarlet or what may be termed phlegmonous inflammation now surrounds the dark gangrenous portion of skin, which is about the size of a half crown in extent; and the contiguous parts have a less brawny feel. Pulse 90, soft, and the patient free from any particular pain. Wears a poultice to the part and takes saline mixture.

March 1. But little constitutional derangement is manifest. The eye examined to-day, but presented no unnatural appearance. Neither of the tarsi are implicated, although the swelling commences immediately below the lower one. To continue as before.

Mr. LAWRENCE observed, that BEER only mentions two cases wherein such a sudden change had taken place, and those resulting from the sting of bees, whereas, in the present instance, the mere contact of the leather had produced it. He also remarked that the only author who had mentioned any case like the present was M. DELPECH of Montpelier, who has described two or three cases as occurring in butchers and tanners, where the parts went into a state of mortification in the space of a day or two after the occurrence of the accident, although there was no severe contusion of the parts. He ascribes it to some peculiarity in the skin with which they were struck.

March 7. The process of separation goes on favourably; that portion of the slough which is nearest the eyelid has become detached, and is found to extend to some depth. The bowels are kept open by medicine, and a poultice is applied to the part.

March 10. A portion of the slough was removed to-day. For the last two days, as he has had a feeble pulse and complained of great weakness, six ounces of wine, daily, have been allowed.

March 13. The whole of the slough has now been detached, and, as was suspected, the tarsus is quite undermined along its central part, which has caused its dropping, and, consequently, a degree of ectropium. The surface of the sore discharges pretty freely, but has a healthy aspect. Continue as before.

March 16. Every thing to be omitted but the wine.

March 19. The edges of the sore have already considerably approximated, and the granulations have nearly rendered it a mere superficial ulceration. Continue as before. Mr. LAWRENCE says, that he shall be obliged, at a future period, to remove the everted portion of the conjunctiva palpebræ.

March 23. The ectropium is lessened, and cicatrization of the sore only now remains to complete the cure. The man was permitted to leave the hospital, and to continue his visits to the Eye Infirmary if he found necessary.

In reference to this case LAWRENCE observes, in his note, "the essential circumstances of this case were a reddened and thickened state of the skin on the cheek, just below the eye-lid, presenting, at the first view, the aspect of incipient erysipelas; speedy mortification of the reddened part, and its slow separation, the mortification including the subjacent textures, so that the cicatrix was fixed to the bone, and the lower lid partially drawn down; absence of constitutional disturbance.

"In the other instances," he continues, "both of which were persons employed in a horsehair manufactory, the skin had sloughed before they came to the hospital. The affected portions were circular, the size of a shilling in one, on the front of the chest; that of a sixpence in the other, on the fore arm. There were no other local symptoms, nor the slightest constitutional disturbance."

Turchetti (*a*) has given, under the name of Anthrax, an account of some cases of malignant pustule, which occurred in 1841, after eating diseased flesh of cattle which had died of an epidemic anthrax of the tongue, and had been sold in the market of Fuceechio. In some persons, small, and very painful tubercles, with a red areola, or small whitish pustules, encircled with purple or violet, appeared on the face, lips, neck, or arms, gradually increasing in size until in the space of from one to three days they presented the genuine characters of anthrax. In the greatest number of these cases the slough separated in the course of a week, leaving a more or less healthy ulcer, which cicatrized speedily. In the more severe cases the pustules ran together, the inflammation spread like erysipelas, with extensive livid swelling and obstinate disorder of the alimentary canal. The sloughs did not separate for a fortnight, and left very foul ulcers, which healed with great difficulty. Two elderly persons died of this disease. A young man, eighteen years old, was attacked twenty-eight hours after taking this food with an anthrax on the left upper eyelid, whence followed mortification of the whole of that side of the face and neck, and part of the chest. At the end of a fortnight the slough cleared off, leaving an enormous ulcer, which suppurated freely and healed slowly.

Dr. Wagner (*b*) relates several cases of malignant pustule produced in man and beasts, both by contact and by eating the flesh of diseased animals, which happened at the village of Striesa in Saxony. On the 13th of July, 1834, a herd of cattle having been brought from the pastures to the village, the bull fell to the ground, and was incapable of getting up again. Supposing that it had met with some injury in the loins which would render it useless, it was destroyed by shooting through the head, as happened to be most convenient, and then, having been dressed and cut up by two labourers, the meat was distributed among the villagers. A few days after, some more cattle on the same farm died, and were skinned by the same persons; but the meat was not used as food, as almost all the persons who had eaten of the first beast had felt more or less unwell, mostly, however, complaining only of weight at the pit of the stomach, and pain in the belly, without fever: but, several, especially the two persons who had both dressed the animal and also eaten its flesh, complained severely of soreness of the limbs, dizziness and debility. Between the 15th and 18th of the month several more beasts dropped and died without any previous illness. On examining their bodies the spleen was found completely gangrenous and in so broken up a state that when cut into it presented a black paste-like mass, which readily flowed out: there were also other inflammatory marks in the belly, and hydatids here and there beneath the skin, especially about the neck. One of the flayers, notwithstanding his uncomfortable feelings, proceeded to a village three leagues off, which he accomplished; but, on attempting to return, was attacked with colic and vomiting, and some hours after was found on the ground suffering severe pain, and passing black blood by stool; his limbs were cold, and soon became attacked with cramp; the whole body like ice; the eyes sunken; and he died vomiting, passing bloody stools, and under great anxiety. One widow woman, of thirty years, who had eaten the flesh, but otherwise not touched the animal, complained of oppression at the heart, and weight of the limbs, had a black pustule on the thigh, felt herself very ill in the evening, went to bed, and early in the morning was found dead. Other persons had pustules on different parts of the body. Two very remarkable cases occurred eight days after any beast had been affected with diseased spleen; both were women, one of twenty-six, and the other of fifty years, and in them the pustules were well marked, and the general symptoms similar to the other cases. The latter patient said she had been bitten by a fly upon the back of the neck, at which part the carbuncle appeared; and the former, that she also had been bitten on the right upper arm, by a

---

(*a*) Sopra alcuni casi di Malattia Carbonchiosa nata per ingestione delle carni di bue perito di glosso-anthrace; in Omodei's Annali Universali di Medicina, vol. cii p. 276. 1842.

(*b*) Uebertragung des Milzbrandgiftes auf Menschen und Thiere sowohl durch Berührung, als durch Genuss des Fleisches; in Hufeland's and Osann's Journal der practischen Heilkunde, October, 1834, p. 1.

gnat. Upon inquiry, **Wagner** found that the skin of one of the infected beasts had been hung on a neighbouring wall, and thought it very possible that the insects might have been attracted to them by the smell, and had thence conveyed the poison.

A very interesting paper upon malignant pustule has within the last two years been published by Dr. **Bourgeois** (*a*) illustrated with numerous cases. He states that the disease appears in from one to three days on the point where the *virus charbonneux* has been deposited, as a little reddish spot almost always of a deep hue, sometimes accompanied with itching, at other times without. It resembles a gnat-bite, is very ephemeral, and soon followed by a little vesicle slightly puckered, of the same colour, containing a small drop of reddish serosity. Sometimes, instead of this mark, the vesicle is preceded by a solid pimple as big as a pin's head, more or less brown and rosy in some cases. The vesicle thus formed is accompanied with a sensation of great itching, and sometimes shivering, but is rarely painful. The patient scratches off the vesicle with his nail, and the itching generally ceases for a few hours, after which, around the scratched pimple, which is dry and yellowish, a regular circle of vesicles, similar to the first, but larger, are formed. In the centre of the circle, now only a few millimètres in diameter, a little brownish depression, deprived of its cuticle, and formed by the skin, on which rests the primitive ampulla, mortified, and forming a dry and very hard scar, and including the whole thickness of the skin. This continues enlarging, and fresh vesicles are formed around its margin. In from twenty-four to forty-eight hours the flesh on which the pustule rests swells, hardens, and forms a tumour more or less sensible, rarely deficient, and generally roundish, but sometimes oval, and of variable size; this he calls the *tumeur charbonneuse*, on the top of which, but rarely occupying its whole extent, is the pustule. That part not covered with vesicles is of a livid red, and spreading more or less on the neighbouring tegument. The middle part of the tumour is especially depressed, but the whole limb, head, trunk, or several of these parts, may simultaneously acquire an enormous size. As the pustule continues increasing, the redness spreads further, and fresh vesicles are developed. At this time the parts, if touched, have, in many cases, a hardness equal to that of a schirrous breast, but gradually soften at a greater distance from the centre, become tremulous, and even œdematous. But **Bourgeois** says he has never noticed the emphysema mentioned by authors, and copied by one writer from another. The heat of the diseased part, at first very great, by degrees diminishes, till it becomes quite cold. On the limbs red tracks of inflamed superficial absorbents are constantly noticed.

Before the parts in the neighbourhood of the tumour swell, there is most generally constitutional impregnation; the patient has lassitude, headache, the tongue is covered with a whitish coat more or less thick, the appetite diminishes, the pulse is full, rather frequent and soft. More rarely these symptoms do not appear till the disease is accompanied with considerable swelling.

If the disease be not arrested, the swelling extends more and more; the parts become enormously swollen, the phlyctænæ increase in number, and the scar in size, with scarcely any pain, but there is only weight and numbness of the affected parts. The general symptoms, however, become more formidable, the pulse small, quick, narrow, depressible and irregular; frequent vomiting of yellow or greenish bilious matter; violent thirst, faintings; singing in the ears; somnolence; urine scanty, red and brick-dusty; difficult motions, but at other times, and, very rarely, very fetid purging; the skin, at first hot and perspiring, becomes covered with cold clammy sweat; respiration more or less difficult; in the greater number of cases the intelligence remains undisturbed, but in some there is violent delirium. Subsequently the pulse ceases at the wrist, the body is covered with a cold sweat; the voice quenched; the skin becomes bluish; there is a sensation of burning heat within the body; unquenchable thirst; threatening suffocation; the patient cannot sit up; no urine; extreme anxiety, and finally death puts an end to this frightful condition, generally without pain.

Bourgeois says, that he has never observed the dull delirium mentioned in books, and that, with the exception of one case in which the patient had evidently an affection of the brain, all he saw were sensible to the last. Nor has he ever seen the enormous eschars attacking all the soft parts of a limb or spreading to a great extent, as mentioned by writers in general.

Authors have usually divided the disease into four stages, without including that of the incubation of the disease: these, however, **Bourgeois** considers arbitrary, and thinks that there are only two distinct periods in the course of malignant pustule; the first commences with the appearance of the primitive malignant spot, which he calls the

---

(*a*) Mémoire sur la Pustule Maligne, spécialement sur celle qu'on observe dans la Beauce; in Archives Générales de Médecine, &c., Fourth Series, vol. i. pp. 172, 334. 1843.

local period or *first period.* The second, which he designates under the name of the *period of impregnation* or *intoxication*, commences with the first general symptoms and terminates only with death or cure." The course of the disease is very variable; it may terminate in two or three days or extend to the fourteenth. The first period is generally the shortest but he has noticed it running on to the fifth day; the second varies from thirty-six hours to eight or nine days.]

For the Literature of Malignant Pustule, see p. 97.

35. Hospital Gangrene (*Gangræna nosocomialis*, Lat.; *Hospitalbrand*, Germ.; *Pourriture d'hôpital*, Fr.) consists of a peculiar decomposition of organic parts appearing under manifold forms. A wound or sore begins to be painful, the edges inflame, the suppuration becomes less and of a serous character. Some days after, on certain parts, or on the whole extent of the wound appears a whitish, thin, semi-transparent membrane pretty firmly connected with its surface, which increases in thickness and extent, and gives the whole surface a grayish-white appearance. This mass cannot be removed, and, if it be attempted, only a part of the whole which is firmly connected with the wound, can be removed. The wound increases in all directions; the edges become still more painful, œdematous, and the œdema spreads. Sometimes hospital gangrene commences also with painfulness of the suppurating surface; but upon it are observed more or less deep cavities, the edges of which are dusky red, and covered with yellowish, white, consistent pus. These ulcerous spots increase and run together; a bloody ichorous fluid is secreted, and the surface of the sore increases in all directions. Lines of inflamed lymphatic vessels commonly stretch to the neighbouring glands. The destruction is often restricted to the cellular tissue; but, in more decided cases, the muscles and all parts without distinction are destroyed. Bleeding often occurs from the destroyed vessels. The bones resist for a long while, but finally give way.

With these local appearances there is always loss of appetite, pain in the region of the stomach, disposition to vomit, costiveness, loss of sleep, a quick and rather weak than strong pulse, hot skin, great anxiety, and restlessness. In the more severe form of the disease all the symptoms of typhus fever come on. These general symptoms often precede the local. The severity and course of this disease as well as its continuance vary in different persons. If it be long continued or often recur, hectic fever and exhausting purging at last set in.

In some cases the hospital gangrene arises in form of a little inflamed pimple or vesicle, without any preceding injury to the part being perceptible (*a*). Hospital gangrene is quite different from the scrofulous complication of sores and wounds.

[Liston (*b*) gives the following brief account of hospital gangrene, as it appeared in University College Hospital, in the year 1841. The case he mentions followed the removal of some metacarpal bones and fingers. "All at once, the stump, which had been healing kindly, assumed a carious appearance; it became enormously swollen within a few hours, and profuse hæmorrhage took place, which there was considerable difficulty in stopping. This might have been, and was sure enough by some who saw it, taken for malignant disease; but it was exactly like what I had seen before in unhealthy seasons, and in badly-regulated hospitals. The season was a very severe one; there had been a great snow-storm, with very cold weather of long duration. Not many days passed over before a number of wounds assumed the same appearance; the parts got puffy round about them, the discharge became slimy and tenacious, very putrid; and bloody fetid gas filled the cellular tissue around them. They extended rapidly, presenting a circular form. Many patients lost a considerable quantity of

---

(*a*) Thomson, as above, p. 460.

(*b*) Lectures on the Operations of Surgery, &c., in Lancet (New Series), vol. i. p. 57, 1844–5.

blood; in fact, we were visited by a rather rare disease, hospital gangrene, one which I trust I may never see again. Luckily, out of a good many patients who were so attacked, and in all parts of the hospital almost simultaneously, not one perished. Many of the wounds and ulcers were frightfully extended; but they speedily got clean, and healed soon afterwards very kindly. * * * After the separation of the sloughs, a *circular* clean granulating surface was left. We were at a loss to account for this invasion: there was nothing as regarded the hospital, its ventilation, or drainage, or management, the dressing of sores, &c., that could be blamed. The disease came upon us suddenly, and as suddenly disappeared; and I need not tell you that we have seen nothing of the kind since."

My friend ARNOTT informs me that in January, 1835, in one of the female wards of Middlesex Hospital three cases occurred which might be classed under the head of hospital gangrene, of which the following is a short account:—

CASE 1.—The disease attacked a common ulcer of the leg; the surface became black and pulpy, with a broad very red margin of integument, a raised edge, and great pain. From the size of half-a-crown, the disease extended and occupied, ere it was stopped, a space of a large wash-hand saucer, exposing the muscles and bone. It was arrested by the application of pure nitric acid, and the removal of the patient into another ward.

CASE 2.—The disease appeared on an ulcer by the side of the anus, presented the same character, but was arrested by balsam of Peru, locally, and a grain of opium every six hours, internally. The disease recurred, and the patient was removed from the hospital.

CASE 3.—A punctured wound of the chest did not heal, but that of the integument enlarged by the conversion of the tissue into a grayish pulpy substance, (not black, and without the fiery margin and intense pain of the other cases,) more like phagedæna. It was stopped by balsam of Peru. "I have never seen," he says, "a similar case in the Middlesex Hospital before or since."

I have mentioned the above cases of hospital gangrene, because they are, as far as I can ascertain, the only instances of the disease which have been seen in either of the London hospitals for many years. Cases occurred many years since in the old Westminster Hospital, and also in the York Hospital at Chelsea, which latter being a military establishment, the disease was believed to have been brought home by the sick and wounded soldiers from abroad. With these exceptions, I have the best grounds for stating that in no other hospital in London has it existed in the memory of either of the present surgeons; so that it is a disease entirely unknown to them, excepting to the few who have seen it elsewhere.

LAWRENCE (*a*), speaking of sloughing phagedæna, observes "that these occurrences generally take place in women of the town under the particular circumstances I have now stated; but it is by no means exclusively confined to cases in which the origin might be supposed to be *venereal.* I remember a very bad instance in this (St. Bartholomew's) hospital, in a case that was under the care of Dr. LATHAM, by whom I was requested to see it on account of the sloughing phagedæna. It was a young woman who had had the small pox very badly. The disease had rendered her very weak, and diarrhœa came on. There was a considerable discharge from the vagina, and a constant moisture of the parts by a discharge from the rectum. Thus the skin of the nates became highly inflamed, and in fact a large excavation of sloughing phagedæna formed on each buttock, and she was reduced to a very low state by the disease. Dr. LATHAM asked me what I thought could be done; and, having examined her, I thought badly of the case, but that we might destroy the excavations in her buttocks, which were nearly as large as a good sized teacup, and possessing all the characters that I have mentioned. They were treated by nitric acid applied with lint wrapped round the end of a probe till the sore was saturated with it, and a brown escar produced; the surrounding parts having been previously well dried, to prevent the spreading of the acid beyond the sore. Port wine was liberally allowed her and she got well. This was a cause of a common kind, in which you could not ascribe the effect to syphilitic disease. Now, as far as I can understand the affection called *hospital gangrene,* it is the same as the sloughing phagedæna I have now described." (p. 454.) I think there is little doubt that this was a case of hospital gangrene and not of the so-called sloughing phagedæna. But it is difficult to make out whether LAWRENCE holds them as distinct or as the same disease; though probably the former, as, in speaking of "the treatment" of hospital gangrene, specially, he says, it, "in other respects, is the same as I have mentioned for sloughing phagedæna." (p. 455.)

(*a*) Lectures, as above.

I cannot agree with **Samuel Cooper**, that the sloughing phagedæna, of which an account, founded on the cases to which **Lawrence** refers in his Lectures, is given by **Welbank** (*a*), "certainly resembles hospital gangrene," as described in books. The sloughing phagedæna was certainly an endemic supervening on venereal excoriations or sores, and *not* hospital gangrene. I shall advert to it hereafter, in speaking of chancre, or venereal ulcers.

The only cases that I have seen, with the slightest resemblance to hospital gangrene, were the sloughy stumps now and then occurring, perhaps more frequently during those years, formerly, when our wards were much troubled with erysipelas. The operation would either seem to be going on favourably for two or three days, the patient comfortable, and adhesion in progress, when a sudden change would set in, the stump become painful, swollen, hard, and red, the un-united part become sloughy, and the united part falling asunder, and soon also becoming sloughy; or, the stump never making any attempt at union, but soon becoming painful, swollen, and sloughy. In either case, the patient himself hot, dry, flushed, with brown tongue, and foul alvine discharges, the pulse quick, irritable, delirium and death supervening. I said such cases occurred, perhaps, more frequently when erysipelas was rife; but they really do happen when no erysipelas is in the ward at the time, nor has been for many months, and they occur not unfrequently in primary amputations in stout persons who have been accustomed to large quantities of beer or spirits, or of both, and from which they are not unfrequently entirely at once (and, as I consider, improperly) debarred; and hence, with a greater call than usual upon the powers of the constitution, are left to meet it with diminished means. Such cases are to be considered merely as resulting from want of power; but they are never epidemic or contagious, and must not be confounded with, hospital gangrene, which, however frequent it may be elsewhere, is, in London, at the present time, and has been for years, unknown by personal experience to most hospital surgeons.—J. F. S.]

36. The characteristic of hospital gangrene is its quick extension and the decomposition of the tissues without any special residue; if the grayish-white mass in certain cases be not so considered. Hospital gangrene is an extension of a wound or of a sore intermediate between ulceration and mortification.

37. The cause of hospital gangrene is the operation of a peculiar contagious matter, either upon wounds and the ulcerated parts or upon the whole body. The contagion develops itself usually in hospitals, where the air is deteriorated, many patients huddled together, and the bandages not kept clean; specially in unhealthy places, as gaols and so on. We know not how long the contagious matter may retain its activity. Probably the constitution of the atmosphere, the weather and climate influence the development and character of hospital gangrene. The susceptibility to contagion is not diminished by its having once been acted upon; on the contrary, it seems to have increased. The contact of the contagious matter with the wound is either the consequence of want of care in dressing it, its long exposure to the action of the air infected with contagion, or its having been covered with bandages in which the poison is retained. The contagion may happen to every person, and in every kind of wound and ulcer: it rarely, however, alters specific ulcers, whilst on the contrary a bilious constitution, mental affections, great feebleness, typhus fever, appear to be most favourable to it. The character of the disease itself may be changed by the constitution of the patient, and by the state of the weather; it may even become inflammatory, in which case the wound is encircled with a red ring, the pain is severe and throbbing, the pulse quick and hard, and the bleeding which occurs produces relief. Hospital gangrene is always a very dangerous complication of wounds and sores. Accidental circumstances may render the danger still greater; for instance, if it be impossible to give the patient

---

(*a*) Medico-Chirurg. Trans., vol. xi. 1821.

attacked with the disease better air and better nursing, and so on. Left alone, hospital gangrene is usually fatal. If it have proceeded to a certain extent, art is rarely of any avail.

For the Literature of Hospital Gangrene, see p. 98.

38. After the appearances and terminations of inflammation, which have been described in general terms, we now come to those variations which inflammation may offer to our notice.

The existence of inflammation depends always on unnaturally raised vital processes: manifold circumstances, however, may change the appearances and course of inflammation, and these changes are only to be considered as modifications of simple inflammation; and the more so, the less they correspond to what we understand by increased vital action. The inflammation may be classed, 1st, *according to its appearances and course;* 2nd, *according to its causes;* 3rd, *according to the structure of the parts attacked.*

39. If the inflammation make its appearance with a certain intensity of its symptoms, and proceed rapidly, it is called *acute;* but, contrariwise, *chronic*, when the intensity of the symptoms is slight and their duration protracted, which condition may be either primitive or consecutive, depending on the constitutional condition. In regard to its character inflammation is further divided into *simple*, *erethitic*, *torpid*, *malignant*, and *obscure*. In *simple inflammation* all the symptoms of inflammation are present in a corresponding degree; it runs a speedy and most commonly satisfactory course; it is almost peculiar to strong persons, who have good health; its termination, if not resolution, is generally suppuration. The *erethitic* and *torpid* character of inflammation are merely modifications according to the *constitution of the patient* and the *degree of the inflammation*. In the *erethitic inflammation* the symptoms have not the same degree of severity as in simple inflammation; the sensibility is, however, distinctly increased, and it therefore especially appears in persons of delicate constitution. The *torpid inflammation* has a remarkably tedious course, and its symptoms seem to depend rather upon a local obstruction of the circulation in the capillary-vascular system than upon an accelerated vital activity; all the signs of active congestion are wanting, the part is not bright red, but dusky and brownish. It occurs specially in weak, reduced, cachectic subjects. Simple inflammation may also, under improper treatment, assume a torpid character. *Malignant inflammation* (*Inflammatio maligna, gangrænosa*) is often painless, or accompanied by an obtuse, heavy pain and dusky redness: its cause is sometimes manifest as the effect of deleterious or contagious matter; at other times, it is unknown: it supervenes on typhus and putrid fevers, and usually runs into gangrene. *Obscure inflammation* (*Inflammatio occulta, clandestina*) is that which is little or not at all indicated by symptoms.

40. Inflammation is divided, according to its different causes, into *idiopathic*, *symptomatic*, *specific*, and *sympathetic*. *Idiopathic inflammation* is the consequence of external violence; it exists as a local disease, and its severity is regulated by the degree of the injury and the condition of the subject. *Symptomatic inflammation*, at least the definite form under which it first appears, depends on internal causes, and the inflammation itself is to be considered only as a reflection of the general disease. If this be of a specific nature, as syphilis and so on, the inflam-

mation is said to be *specific*. *Sympathetic inflammation* is the consequence of a consensual change in the mutual relations which one part holds to another, by which their diseased affections become shared by both. The *metastatic inflammation* which passes from one organ to another is in close connexion with the sympathetic.

Symptomatic inflammation is either the original symptom of general disease, or an originally idiopathic inflammation acquires, through the general disease, a definite character.

41. In whatever part inflammation may occur, its peculiar seat is always in the *capillary-vascular* system. But its symptoms vary according to the different conditions of the affected part.

Inflammation of the *Skin*, if not severe, terminates in resolution with scaling of the cuticle, and not unfrequently also with dropsical swelling. In a more active inflammation a fluid is poured out beneath the cuticle producing vesications and pustules. If the inflammation be tedious without being active, the cuticle is destroyed; the fluid poured out by the exposed vascular net thickens into crusts. If the inflammation extend to the subjacent cellular tissue, it is generally severe and runs into suppuration.

Inflammation of the *Cellular Tissue* is usually accompanied with much ill-defined redness, with firm elastic swelling, much tension and throbbing pain; it does not resolve except it be in a mild form; its usual termination is suppuration, not unfrequently gangrenous destruction of the cellular tissue.

[This important affection of the cellular tissue, which has only within the last twenty years been particularly noticed, though commonly spoken of under the common title of erysipelas, is described more at length by our author, at page 103, "as a metastatic deposit in the cellular tissue, and one of the causes of his *Erythema symptomaticum seu consensuale*. Doubtless, it may be, and occasionally is, metastatic; but, generally it is idiopathic. It has of late years become common, and is a very rapid and dangerous disease, unless early and properly treated. Its importance is so great, that it is as fully entitled to a proper chapter as erysipelas, from which it most decidedly differs. But it will be, perhaps, more convenient to insert what I have to add where the subject comes under consideration in our author's arrangement, rather than to remove and drag his paragraphs into places for which he had not intended them, under pretence of making his meaning more clear, as if the author did not best understand his own view of the subject he discusses; a proceeding which has been occasionally practised in English translations, which I think cannot be too much deprecated, and the least inconvenience of which is, that it is not unfrequently impossible to refer from the original to the translation, or from the translation to the original.—J. F. S.]

Inflammation of the *Glands* mostly exhibits not very acute but rather dull pain, no great heat, very solid circumscribed swelling, which also extends itself into the surrounding parts. Its termination is similar to that of inflammation in the cellular tissue, except that glandular inflammation most commonly assumes a chronic character, and then easily passes into hardening.

In inflammation of the *Mucous Membranes*, their secretion is stopped at the onset; at the same time, increased warmth and sensibility, heavy pain and great redness make their appearance, a secretion of thin somewhat acrid fluid, the thickness of which increases, becomes creamy, and of perfectly mild character. No tissue so readily as the mucous membrane acquires a morbid disposition to inflammation. When affected with long-continued inflammation their spongy cellular tissue becomes loosened, swelled, thickened, and the vegetation on it often is so changed that new formations, polypous excrescences, are developed. In active inflammation, or in long-continued flow of mucus, ulceration and destruction of the underlying parts frequently occur. Very rarely do inflamed mucous membranes become adherent.

[In reference to the kind of inflammation which occurs in mucous membranes, HUNTER says:—"In internal canals, (I make a difference between an internal cavity and a canal; they are very different in their construction, their uses, and also their mode of action in disease are very different,) where adhesions in most cases would prove hurtful, the parts run immediately into the suppurative inflammation, the adhesive inflammation in common being excluded; such parts are the internal surface of the eyelids, nose, mouth, trachea, air-cells of the lungs, œsophagus, stomach, intestines, pelvis of the kidneys, ureters, bladder, urethra, uterus, vagina, and indeed all the ducts and outlets of the organs of secretion, which all these parts mentioned may be in some degree reckoned, and which are commonly called mucous membranes. In such parts, if the inflammation is but slight, the suppurative in common takes place, which is almost immediate, as it is not retarded by the adhesive stage, which accounts for the quickness of suppuration of these parts in many cases. * * * Since those surfaces are, in general, secreting surfaces, suppuration would appear to be only a change in the secretion; and I think I have visibly seen, or could visibly trace, the one change gradually leading into the other; the different parts, therefore, of which the pus is composed, will not always be in the same proportion, so that the matter will seem to vary from true matter towards that of the common secretion of the part, and *vice versâ*; but this does not alter the position, for it is common to matter from a sore, and even common to our ordinary secretions. If this inflammation which produced suppuration on those surfaces becomes more violent, or has something of the erysipelatous disposition, we find that it moves from the suppurative to the adhesive, and throws out the coagulating lymph." (p. 241, 2.)]

The *Serous Membranes* have great disposition to inflame; the inflammation is very painful, usually appears suddenly, spreads quickly, and easily passes into resolution, adhesion, transudation, and mortification, but rarely into ulceration. Serous membranes often thicken, either by the cellular tissue upon their external surface or by plastic membranes, or even in their own proper substance. Chronic inflammation of *serous membranes* appears mostly in the form of dropsical affections.

[Serous membranes are the circumscribed cavities which, with "the cellular membrane or the body in general," belong to the first order of parts into which the body is divided by HUNTER, and in relation to which he observes:—"When inflammation takes place in the first order of parts, it is commonly the adhesive; but it will be according to circumstances whether the suppurative or the ulcerative follows first." (p. 253.) "The adhesive inflammation serves as a check to the suppurative, by making parts which otherwise must infallibly fall into that state, previously unite, in order to prevent its access, as was described in the adhesive inflammation being limited; and, where it cannot produce this effect so as altogether to hinder the suppurative inflammation itself from taking place, it becomes, in most cases, a check upon the extent of it" (p. 365;) of which inflammations of the pleura, or surface of the lungs, presents a good example; "the adhesive inflammation takes place, and the surfaces are united, which union going before the suppurative confines it to certain limits, so that distinct abscesses are formed in this union of the parts; and the whole cavity of the thorax is not involved in a general suppuration." (p. 366.)

The peculiar disposition of serous membranes to assume in preference adhesive inflammation is remarkably contrasted with the equally special preference of mucous membranes for the suppurative inflammation. The construction of closed cavities by the serous, and of canals by the mucous membranes, afford the ready explanation of these peculiarities. Any opening, therefore, in a serous membrane puts it in an unnatural condition, and, consequently, if it were attacked with suppurative inflammation, the pus produced requiring an aperture for its escape, such unnatural state would be induced, and the functions of the membrane interfered with or destroyed: therefore, most commonly, adhesive is the kind of inflammation occurring, which only diminishes the cavity (the lesser evil) without opening it; and when, more rarely, suppurative inflammation ensues, it is most usually shut off from the general cavity by adhesive inflammation, as in spurious empyema; and only in few cases existing without such adhesion. Whilst, on the contrary, were mucous canals attacked with adhesive inflammation, they would be at once blocked up and the most dangerous consequences ensue, as occasionally observed in croup, and so on; but they prefer suppurative inflammation, and no such danger accrues.—J. F. S.

The inflammation of serous membranes sometimes runs on to suppuration. This was noticed by **Hunter**, who observes:—"In spontaneous suppurations, one, two, three, or more parts of the inflammation lose the power of resolution, and assume exactly the same disposition with those of an exposed surface, or a surface in contact with an extraneous body. If it is in the cellular membrane that this disposition takes place, or in the investing membranes of circumscribed cavities, their vessels now begin to alter their disposition and mode of action, and continue changing till they gradually form themselves to that state which fits them to form pus. * * * From hence it must appear that suppuration takes place upon those surfaces without a breach of solids or dissolution of parts, a circumstance not commonly allowed; and, when got beyond the adhesive state, they become similar in their suppuration to the inner surfaces of internal canals." (p. 378.)]

In inflammation of the *Fibrous Tissues* the pain is sometimes very severe, sometimes changeable, deep-seated, increased less by pressure than by the motions of the part, the warmth is much increased, the swelling, according to the difference in structure of the neighbouring parts, sometimes hard, sometimes soft, the redness slight, often scarcely discernible, but often far outspread. Its terminations are resolution, metathesis, gouty concretions, gangrene, and suppuration, which is confined to the cellular tissue connecting the fibres together, whereby a laminated arrangement is produced.

Inflammation of the coats of *Arteries* (1) is either generally diffused, with violent pulsation of the heart and arteries and high fever; or it is confined to one spot, when the symptoms are commonly obscure. The acute *partial* inflammation of arteries commonly runs into adhesion; the *chronic*, which mostly depends on diseases with little power, into thickening, loosening, ulceration, deposition of calcareous masses, whence (2) commonly results the origin of aneurisms.

[(1) Arteritis, as it is now generally called, is, probably, if idiopathic, an inflammation of the internal only, and not of all the coats of an artery, but, if traumatic, arising either from wound, from ligature, or more extensive pressure and the like, or if the inflammation have been communicated to the artery from neighbouring diseased parts then all the coats of the vessel become affected, and may pass through the various forms of inflammation. "The active and violent pulsations," says **Bouillaud** (*a*), which the arteries in the neighbourhood of a very acute whitlow perform are the type of those which characterize general arterial irritation. And he also observes, that there is besides the increased force of the arterial pulsations, a sensation of heat and uneasiness in the region which the inflamed artery occupies." (p. 411.)

Redness, thickening and friability are the appearances described as presented by the internal coat of an artery under acute inflammation; the redness and thickening from swelling of the membrane occurring simultaneously.

Hodgson (*b*) describes four cases, in the first of which the internal coat of the aorta was of deep red colour; a great effusion of lymph had taken place into its cavity, and become very intimately connected with the internal coat, and a plug of the lymph extending into the left sub-clavian artery nearly obliterated its cavity: these appearances accompanied a violent pneumonia. In three cases, viz. of carditis, pneumonia and bronchitis, he also saw it, but the effusion of lymph was less; in one case the aorta was throughout of a deep scarlet colour, and a little above the semi-lunar valves the coats of the aorta were distended with lymph. (p. 5.) He also quotes from **Portal** (*c*) a case of sudden subsidence of measles, in which "the aorta was throughout nearly its whole extent very red, and its walls swollen and soft, especially in the thoracic region, near the diaphragm, where it was covered with varicose vessels; the internal coat was swollen and softened." (p. 127.)

(*a*) Dictionnaire de Médecine et de Chirurgie Pratiques, vol. iii. Article *Artérite*.

(*b*) On the Diseases of Arteries and Veins, &c., London, 1815, 8vo.

(*c*) Anatomie Médicale, vol. iii. Paris, 1803. 8vo.

Redness, however, is not always present in an inflamed artery, and it often exists when there is not any inflammation, when putrefaction has commenced, in consequence of the blood transuding. And Bouillaud says:—"It is right to observe, that the redness of the internal membrane of arteries, even in the case where one is disposed to refer it to acute arteritis, is not produced, at least in the great majority of cases, by a *capillary injection*, but rather by a kind of *tinting* or *fixation* of the colouring matter of the blood on the internal membrane. Under this new point of view the inflammatory redness differs not essentially from that which is called *cadaveric*." (p. 403.) In inflammation of the whole thickness of the arterial walls, the outer coat is generally red, in consequence of the active and free injection of the numerous vessels which everywhere penetrate them; and sometimes there is even a slight infiltration of blood. Bouillaud further observes, that "after the internal coat, or even all the coats of an artery has been some time inflamed, it is easily detached in large flakes, the subjacent cellular tissue becoming friable." I apprehend, however, that what he considers as flakes of the internal coat are really deposits of adhesive matter upon the coat, and not portions of the coat itself. The result of acute arteritis is then deposit of adhesive matter, and, as already mentioned in one of Hodgson's cases, sometimes sufficient to fill up the tube of the artery, though, from the friction of the stream of blood upon the deposited lymph, Bouillaud considers that it is drawn into the stream, and that rather the "inflammation determines the coagulation of the blood circulating in the artery, and thus is easily explained how the secreted matter in addition to the mass of coagulum, may produce arterial obliteration." (p. 407.)

Adhesion of the lining membrane, and obliteration of the arterial tube, is one of the results of arteritis; but, as will be presently shown, the effusion of adhesive matter, and even the coagulation of the blood in the inflamed vessel, do not always cause mortification of the limb, as Dupuytren would seem to consider; that condition depending rather on the number of the vessels affected with inflammation, and the quickness with which the adhesive deposit takes place, so that the supply of blood is cut off before the collateral circulation can come into play. The usual consequences of inflamed artery are seen in the application of a ligature upon an artery, in which case generally the collateral circulation is speedily established and no inconvenience to the limb is sustained, whilst, on the other hand, occasionally the circulation is restored so slowly that mortification to greater or less extent ensues.

The following case of partial arteritis came under my own care, and for its previous history I am indebted to my intelligent friend Crisp of Walworth, whose patient he was.

Thomas Batt, aged 21½ years, a grocer's assistant, about five years prior to the present time, (August 1843,) had an attack of rheumatic fever which lasted six or seven weeks; and since has had several slight attacks of pleuritis, for one of which he was bled, but neither were so severe as to confine him to bed. The bellows sound was always heard over the region of the heart. On the *7th of August* he was seen on account of slight pain in the chest, for which he was ordered some aperient medicine with *vin. antim. potass tart.* The pulse at the left wrist was then felt and *nothing remarkable* observed.

August 9. A. M. Whilst putting on his waistcoat, he was struck with pain like the prick of a pin, about the middle of the left upper arm, and in the track of the brachial artery, which continued for about an hour, and during that time his arm "became dull and cold as low as the elbow." He saw his medical attendant at 10 A.M.; the arm and hand were then cold, and no pulsation could be felt below the arm-pit, at which part the artery was felt beating, but not forcibly, (90 a minute,) and over it great tenderness on pressure. The pulse of the right wrist was 100, and rather more powerful than usual. The ailing arm was ordered to be put in warm water for a quarter of an hour.

4½ P. M. In the same state as the morning; but has had five or six times a sensation of throbbing in the arm, with tingling and numbness of the fingers.

10 P.M. As he continued much the same, six leeches were applied to the arm-pit, and an opening draught given immediately.

August 10, A. M. Caustic was applied to the leech-bites, which had bled all night and were still bleeding, so that he felt rather faint from loss of blood; but the pulse of the right arm is not much affected. No pulsation in the left wrist; but the hand less cold than yesterday. There is great tenderness over the commencement of the brachial artery. ℞ *pulv. colchic.*, *pulv. antim.*, āā gr.v. *hydr. c. cretâ*, gr. x. *quintis horis sum.*

August 11. Much the same: the artery painful on pressure; the powders continued.

August 13. No change since the last report, except that the tenderness over the brachial artery is less and the hand not so cold. His bowels being confined, an aperient draught was ordered immediately, and the powders continued.

August 15. He came under my care at St. Thomas's, and, in addition to what has been already mentioned, he says, that he has long had a sense of weakness as if overworked, and that during the first day of the attack, the dullness and coldness continued extending down to the wrist, but unaccompanied with pain; that for the last two nights his arm has been affected with dull aching pain which has prevented his getting rest, but has subsided during the day. At present he is free from pain, except when the arm is bent or hanging down, under either of which conditions he has pain at the original spot in the middle of the arm. He has much tenderness on slight pressure from the middle of the arm upwards, and the arm-pit in the course of the artery, but none below. The pulsation in the brachial artery below the specially indicated part, is scarcely, if at all perceptible, and above it is slight; at the wrist, in the ulnary artery, there is not any pulsation, but the radial artery pulsates slightly. The pulse of the right wrist is distinct, full and quick. I ordered bleeding from the right arm to twelve ounces, milk diet, and *liq. ant. potass. tart.* ♏ x. *ex mist. potass. citr.* 4*tis*

August 16. He has been relieved by the bleeding; has less pain and more feeling in the arm.

August 17. A careful examination by the stethoscope indicates regurgitation through the aortic valves.

August 22. Complains of having had occasional shooting pain in the fore and middle fingers of the left hand, as if being cut off. No increase of pulsation at the wrist; the upper arm is less tender. He complains of having had pain in the sole of the left foot two days since, which yesterday extended into the great and second toe, so that he could not bend them without much pain; in course of the day the pain subsided at this part and attacked the dorsum pedis, where it yet remains, though less severe than yesterday.

September 5. Pulsation in the left radial artery is now very distinct though small.

September 26. On examination with the stethoscope, distinct bellows murmur with the second sound most decidedly over the aortic valves, and the first loud, short and clear: pulse jerking, regurgitation through the aortic valves, and dilatation of the heart.

October 4. The pulsation at the wrist still continues steady. He complains of having cough with expectoration and want of rest at night; is languid and thin, and his health not improving. ℞ *pil. opii. gr.* 1 *o. n.*, which was, on

October 24. Replaced with *tinct. camph. comp.* ʒj *ex mist. amygd. ter in die*, and, on

October 27. The opium was resumed. He has been gradually becoming more languid without any very distinct cause.

November 3. He spat a little blood, which continued increasing by degrees till

November 5. When he spat a large quantity, and died in the evening. During the last three days he has been so much exhausted, that it was absolutely necessary to keep him up with arrow-root and port wine four ounces daily.

Examination.—*Chest.* Some old pleuritic bands on the left side, but none on the right; the left pleural cavity containing a considerable quantity of serum.

Pericardium universally adherent; its free portion separated from the visceral with great difficulty. Heart enlarged; its apex wide and rounded: both ventricles enlarged; the walls of the left thickened, and those of the right somewhat thinned. Valves on the right side perfectly healthy. On the left the sigmoid valve of the aorta thickly beset or fringed with vegetations. The curtains of the mitral valve thickened and containing points of cartilage and bone. Both aortic and mitral orifices contracted, mainly dependent on the thickening of their individual valves.

Belly. Liver rather enlarged, dark-coloured, and in a state of hepatic venous congestion.

Left Arm. Brachial artery high upon the arm over a space of from half-an-inch to an inch, of a red colour, and its coats thickened, containing at this point a plug of coagulable lymph adherent on one side to the lining of the vessel. Below this part the vessel was much contracted to the extent of three or four inches, beyond which it again resumed its original calibre, and there the orifices of three or four minute vessels were perceived.

Adhesive matter may be deposited between the internal and middle coats of an artery, and even pus, of which an instance is mentioned by Andral. The internal coat of the aorta "was elevated by half-a-dozen little abscesses, each about the size of a hazel nut and situated between it and the middle coat; the pus contained in these abscesses resembled the usual pus of phlegmon." (p. 379.)

(2) The deposit of earthy matter in arteries generally involves only their coats, especially the inner coat; upon the exterior of which the earth is held to be deposited, in consequence of the thin internal coat being usually traceable and separable from it, so

that the earth is not in immediate contact with the stream of blood. This, however, is not always the case, for the lining coat sometimes appears to be deficient, or hangs in shreds into the tube of the artery, so that the blood does actually flow in contact with the earthy matter, and the latter is occasionally deposited in such quantities that it completely fills up the cavity of the artery, rendering it impervious, and converting it as it were into a calcareous rod, the particles of which, however, are not in very intimate union: an excellent instance of such conversion of the femoral artery is in the Museum of St. Thomas's Hospital.

The deposition of calcareous matter in the coats of arteries is not restricted to old persons; for **Portal** observes:—" The vessels of young persons rarely ossify; instances, however, have been noticed of ossifications in the arteries of some children, in whom the ossification of the bones had not proceeded far." (p. 133.) **Hodgson** also mentions, that " George Young possesses a temporal artery, which he removed from an infant of fifteen months old, in which the coats of the vessel are converted into a complete tube of calcareous matter." (p. 23.)

The analysis of the earthy concretions made by **Brande** for **Hodgson** presented 65.5 of phosphate of lime, and 34.5 of animal matter in 100 parts; the latter consisted chiefly of albumen, with traces only of gelatin. No carbonate of lime was discoverable.—J. F. S.

These earthy deposits are not bone as appears from the following statement of **Miescher** (*a*):—" Ossifications of all the arteries very frequently occur which are situated between the innermost and proper tunic, in form of larger and smaller plates, of which the smooth surface turned towards the cavity of the artery, the colour, density and toughness very closely resemble true bone; but, when broken, they always had to me a foliaceous or squamous appearance, very like the scales of an oyster-shell; nor could I ever, though often seeking with the microscope, discover corpuscles or canalicules; the soft substance left after the addition of hydrochloric acid never presented any definite texture." (p. 46.)]

Inflammation of the *Veins*, when partial, manifests itself by the symptoms of inflammation in general; but, when it spreads further and attacks the large venous trunks, then appear violent symptoms, such as a rapid pulse, depression, restlessness, delirium, and so on. The cause of inflammation of the veins is most commonly external injury. Its terminations are, 1st, thickening of the venous coats; 2nd, stagnation and formation of clots; 3rd, effusion of plastic lymph and obliteration; 4th, formation of pulsating swelling; 5th, suppuration and bursting of the venous walls; and, 6th, ossification.

According to **Cruveilhier** (*b*), the symptoms in adhesive phlebitis, as well as in circumscribed suppurative phlebitis, are entirely local, and originate in irritation of the internal coat of the vein, and in the mechanical obstruction, which, by stopping up the veins or the branches of the inflamed venous twigs, opposes the passage of the blood and of the lymph. The pain and fever depend on the inflammation, and the œdema upon the mechanical obstruction to the circulation. In the uncircumscribed suppurative phlebitis, the symptoms depend on infection of the blood. The patient passes suddenly and without intermission from a state not seemingly dangerous to stupor, prostration of power, and to death, like an animal into whose veins pus has been injected.

[Inflammation of the veins or phlebitis as it is now generally called is far from an infrequent disease, and when very active is extremely dangerous. As our author states, the cause of this disease is most commonly external injury; but I have known it to arise spontaneously in the leg, where the veins have had a varicose disposition. The track of the inflamed vein is easily distinguished by its redness, by its feeling like a cord of greater or less length beneath the skin, as thick and sometimes thicker than a goose-quill with protuberances at uncertain distances corresponding to the situation of the valves. This cordlike character depends upon the coagulation of the contained blood, " the coagulating lymph (fibrin) undergoing," as **Hunter** (*c*) observes, " some changes in its passage through the inflamed vessels, which obliges it to coagulate more immediately or much sooner than it would otherwise; for, in those cases of inflamed arms after bleeding, and in inflammations in consequence of other causes, we find that the cavities of the veins are in many places furred over and in others united by means of the coagulating lymph. Now, if this coagulating lymph is similar in its productions to that

(*b*) Anatomie Pathologique. Paris, 1837.

(*c*) On Inflammation, &c.

which we have been describing, it must have been thrown out from the vasa vasorum, these vessels having separated it and poured it into the cavity of the veins, and it must there have coagulated immediately: in this separation, therefore, from the blood, it must have undergone some change, arising from the action of the vessels; for, if this lymph was no more than the coagulating lymph, with its common properties, or the properties common to that which is circulating in the same vein which receives it, it would in such cases only continue to throw in more coagulating lymph, in addition to what was circulating, and therefore probably it would be carried along with the blood to the heart as a part of the common mass. From this we should infer that this coagulating matter is not simply the coagulating lymph such as it was when circulating, but somewhat different, from having undergone a change in its passage through the inflamed vessels, partaking of the disposition of those solids through which it passed. * * * But this may be taken up in another point of view, and upon the same principle; the inflamed vessels may give a disposition to the blood as it is moving slowly along, to coagulate on its surface, and this is probably the more just idea of the two; as we find that the vessels both veins and arteries can give this disposition, and to a very great extent: we find, in the begining of mortification, the blood coagulating in the vessels so as to fill them up entirely, and this, preceding the mortification, seems to be for the purpose of securing the vessel before it is to give way; we, therefore cannot doubt of a coagulating principle being given to the blood from the vessels." (pp. 311, 12.)

Accompanying the redness and cordlike feel there is more or less tenderness, and even actual and severe pain. The inflammation continues to extend towards the heart, presenting, as it proceeds, the same characters. Not unfrequently a chain of little abscesses take place generally at the protuberant valves, which burst of themselves, but are best laid open. The constitutional excitement varies considerably, sometimes is trifling, but sometimes very severe. With constitutional and local antiphilogistic treatment, leeching, fomenting and poulticing, the disease, however, is not unfrequently checked, the inflammation subsides, and the cordlike condition alone remains, which requires some time for its removal. If suppuration in form of little abscesses, as just mentioned, occur, the inflammation oftentimes ceases, and the case does well; but, if suppuration do not occur, then the disease becomes dangerous.—J. F. S.

Attention has long been drawn to the severe form of phlebitis; for, more than fifty years since HUNTER (*a*) observed that "in all cases where inflammation of veins rises high, or extends itself considerably, it is to be expected that the whole system will be affected. For the most part, the same kind of affection takes place which arises from other inflammations, with this exception that where no adhesions of the sides of the vein are formed, or where such adhesions are incomplete, pus passing into the circulation may add to the general disorder and even render it fatal." (p. 26.) And, having seen inflammation propagated along the jugular vein of horses into their chest, and followed by death, HUNTER says:—"But what is the particular circumstance which occasions their death I have not been able to determine; it may either be, that the inflammation extends itself to the heart, or that the matter secreted from the inside of the vein, passes along that tube in considerable quantity to the heart, and mixes with the blood." (p. 25.) This suggestion of HUNTER's was, without having seen a case, converted by ABERNETHY (*b*) into an actuality, when he ascribes the great sympathetic fever occuring in an extensively inflamed vein, not simply to the inflammatory excitement, but also "because irritation will be continued along the membranous lining of the vein to the heart." HODGSON (*c*) copies this statement of ABERNETHY's; for, in the single case of inflamed vein which he gives, he says distinctly, that "the vena cava superior was healthy. The diseased appearances were not gradually lost, but terminated abruptly; the heart was healthy;" whilst "the external jugular and the subclavian veins were filled with pus, and when slit open were found to be much thickened and lined with lymph." (p. 514.) He considers that "the constitutional irritation which is accompanied with symptoms of greater debility than acute inflammation in general, may probably arise from the extent of the inflamed surface, but that it is not unlikely it may be an effect produced upon the nervous system by the pus which is secreted into the vessel being mixed with the circulating blood." (p. 518.) CARMICHAEL (*d*) holds that the symptoms presented in phlebitis "were no doubt owing to the formation of

matter, and the influence which it must produce on the general system when mixed with the mass of blood." (p. 368.) And Bouillaud (*a*) also ascribes the typhoid symptoms to the presence of pus in the system. Travers (*b*), however, does not agree with these writers as to the existence of pus being the cause of the symptoms. He first distinguishes between the inflammation which terminates in the formation of pus, and that which terminates in depositing adhesive matter or lymph, extends to the trunks of the system, and sometimes, it is said, reaching the heart: the former condition is a protracted irritation, causing hectic and ending in exhaustion; the latter a typhoid fever which, speedily producing delirium, terminates within a few days: cases of the first kind, though always dangerous, sometimes recover, but of the second, he believes, never. He then proceeds:—"There have been many conjectures respecting the cause of the fatal termination of these cases, at which I confess I feel surprised; among others, the inflammations, by extension, of the heart or the membranes of the brain and the conveyance of pus into the circulation have been mentioned. Not to insist on the innocuous quality of pus, it should be observed, that the most rapidly destructive inflammation is that which has the true adhesive progress, in which no pus is secreted. But, if we consider the importance of the veins in the economy, the extent of surface which the collective areæ of the venous trunks afford, larger, I imagine, than any of the shut sacs of the body, and the diffused and disorganizing character of the inflammation, we can surely be at no loss to account for the disturbance of the system. It is an error to suppose that any quicker sympathy exists between the constitution and the venous, than the arterial or absorbent system. I say this because I have observed something like that superstitious alarm which is excited by events that we do not expect, and cannot explain, has been produced by the fatal catalogue of tied veins, and a comparison of this with the generally successful cases of tied arteries. All the mystery of veins is, as I have attempted to show, that they are indisposed to inflame, but, when excited, inflame by continuity; and therefore it is that the constitution sympathises so deeply." (p. 286.) In a very excellent paper on phlebitis, Arnott (*c*) deduces from the collation of cases "the total disproval of the assertion, that death results from the extension of the inflammation of the vein to the heart." In none of the ten instances following venesection was the superior cava affected, much less the heart; and, in half this number, inflammation had not reached to the subclavian or even to the axillary vein. In the cases where the inferior cava had become inflamed, the first is the only one in which the heart is represented to have been actually implicated; and here, the deposition of lymph terminating at the entrance of the emulgent vein, the observation is, that there were marks of diffused inflammation extending to the right auricle of the heart, but the signs of adhesive inflammation terminated as above." * * * With the exception of the instance just alluded to, I have only found two others in which it is alleged that the inflammation had extended from the vein to the heart, and in these the description is not very precise. Both cases are mentioned by Ribes (*d*). In one, occurring so far back as the year 1799, where the veins of the arm were inflamed in connexion with gangrene of the hand from chilblain, "traces of inflammation" are stated to have been continued into the superior cava, and even to the interior of the right auricle and ventricle; and, in the other instance, where the saphena evinced some signs of inflammation, in a case of mortification of the leg and foot, it is stated, in the same vague terms, that "the right auricle and ventricle of the heart, as well as the inferior cava at its insertion into this organ, had manifest traces of recent inflammation." It is to be regretted that Ribes has not distinctly specified what the "traces" were which he considered as indicative of inflammation in the lining membrane of the heart. (p. 42, 43.) From Arnott's statement, it appears further that "there are considerable differences in the extent of vein occupied by inflammation in fatal cases of phlebitis. Sometimes the disease has spread into several or most of the veins of a limb from that primarily affected; at others it has not proceeded beyond the vessel in which it originally appeared," sometimes is "limited to a few inches only of a vein," and thus "justifies the inference that the dangerous consequences from phlebitis bear no direct relation to the extent of the vein which is inflamed." (p. 44.) As regards the contents of the inflamed vessels, "in a number of them, where an open wound existed in the vein, pus was discharged from it during life; whilst in fourteen cases out of seventeen, pus, or pus in conjunction with lymph, was present in the vessel after death.

(*c*) A Pathological Inquiry into the Secondary Effects of Inflammation of the Veins; in Medico-Chirurg. Trans., vol. xv. 1829.

(*d*) Revue Médicale for July, 1825.

In two instances, no mention is made of pus, the contents of the veins being described in the one as "adhesive matter," in the other, where the cava was concerned, as "flakes of lymph." In one case only, where the inflammation occurred in a vein previously diseased, or in a vein, the branches of which at least were varicose, neither pus nor lymph was found in the vessel. "It results from this statement, that, although pus is present in the great majority of fatal cases of phlebitis, and that, although it should appear from the character of the general symptoms, and the effects produced upon animals by the injection of a similar fluid into their vessels, the passage of pus into the circulation is probably the principal, yet the circumstances do not justify us in regarding it as the sole, cause of the secondary affection. In addition to the presumed absence of pus in two instances, and its declared absence in a third, it may be remarked that the early appearance of the symptoms in some cases seems scarcely to correspond with the time usually required for the production of pus, as in one which occurred to **Freer**, (quoted by **Hodgson**, p. 551,) where they came on suddenly, four hours after ligature of the saphena." (pp. 44, 45.)

"The secondary affection in phlebitis usually shows itself in from two to ten or twelve days after the receipt of the injury which has occasioned the inflammation in the vein; where the vessel has been previously diseased, sometimes sooner. * * * The duration of this affection offers some variety," (pp. 51, 53,) death taking place at different periods from the fourth day to the end of the seventh week. The remarkable morbid appearances recited by **Arnott** are, "in the chest, effusions of sero-purulent fluid into the cavities of the pleura and pericardium, exudation of coagulable lymph on the surfaces of the heart and lungs, hepatisation of the latter organ, infiltration of pus into its tissue, or small collections like a mixture of pus and lymph, pus also in the muscular substance of the heart. * * * In the cellular substance, intermuscular as well as subcutaneous, pus and sero-purulent fluid have been extensively deposited, sometimes in collections like abscesses, at others, appearing more like an effusion into its cells than as resulting from the common process of inflammation. These collections more frequently occur in the vicinity of joints. * * * In the joints, a most violent inflammation of the synovial membrane, its distension with purulent matter, destruction of the cartilage and baring of the bones. * * * In the eye, opacity of the cornea, injection of its blood-vessels, and destructive changes in its humours or its coats. Besides these affections, there were found in five instances within the cranium opacity and thickening of the tunica arachnoides, effusion between it and the pia mater, and increased secretion into the ventricles. In nine the head was not examined, and in three no morbid appearances were noticed." (pp. 53, 57.) The conclusion at which **Arnott** arives is, "that death in cases of phlebitis does not take place from the inflammation extending to the heart; whilst the history and character of the symptoms which precede this event, the very small portion of vein which is sometimes found to have been inflamed, and the general presence of pus in its cavity, all tend to establish, that the entrance of this fluid into the circulation is the principal cause of the alarming and fatal consequences of phlebitis, a similar influence being perhaps also possessed by any inflammatory secretion from the vein." (p. 61.)

On the inflammation of the femoral and iliac veins, which occurs in puerperal women, which sometimes, but not always, gives rise to *Phlegmasia dolens*, Dr. **Robert Lee** (*a*) observes, that, "whether the inflammation of the coats of the veins be simple adhesive inflammation, or inflammation of a specific kind connected with the puerperal state, and differing, not only in the degree of intensity, but in its essential nature from phlebitis after venesection, it is difficult to determine. The peculiar character of the symptoms seems strongly to favour the latter opinion, though it cannot be denied that the disease occasionally assumes the form of common phlebitis, fatal cases having occurred where pus has been found secreted by the internal coats of the iliac veins, and death caused by inflammation and apostematous deposits of matter in the lungs and other remote organs of the body." (p. 145.)]

In the *Absorbent Vessels*, inflammation arises either from external injuries and so on, or from some morbid matter which they have taken up. It is indicated by painful red swelling of the absorbent vessels up to the nearest gland. It usually terminates in resolution.

[Inflammation of the absorbent vessels may arise without either injury or the absorption of morbid matter, but simply from irritation, as frequently seen in whitlow or other inflamed condition of the fingers or toes, as when they have been chafed or after the

---

(*a*) On the Pathology of Phlegmasia dolens; in Medico-Chirurg. Trans. vol. xv. 1829.

application of a blister. The red streak or streaks which indicate the inflamed absorbent vessel or vessels, is generally little thicker than a stout thread, pale towards its edges, can at first scarcely be called a swelling, but is more like a streak of paint on the skin, and only after some time has a slightly knotted feel. It runs along the limb with great rapidity, and will in the course of a few hours enter the cavities of the trunk. It terminates in suppuration less frequently and less quickly than inflammation of the veins. Generally it subsides as the irritation which has excited it is relieved, and I do not remember to have observed continuance of the cordlike feel long after the inflammation has ceased —J. F. S.

In reference to these red streaks, HUNTER observes:—" These reddish streaks are supposed to be absorbents, becoming inflamed by their carrying a stimulating fluid. I am apt to suppose them to be absorbents; but I do not conceive that this effect arises from absorption. If it arose from such a cause, it should be uniform; the cause should always exist when the effect takes place. It is first to be observed that it only takes place in certain constitutions, in which absorption one way or other explains nothing; and I find upon observation that this effect shall be coeval with the inflammation where no suppuration has taken place. I have even seen it arise from accident, prior to the possibility of inflammation taking place, viz., in the time of the pain arising from the immediate effects of the accident; this was in the finger, from the prick of a clean needle, which had been for some time pricking new buckskin leather; the glands in the arm-pit were sore, sickness attended with its usual symptoms, such as oppression, was nearly immediate. Its direction from the source of the circulation is another strong proof of its not arising from absorption, and its taking place at some distance is also a corroboration of the same opinion. Another strong circumstance in favour of this opinion is, that the morbid poisons do not produce this effect where we know absorption has taken place. Thus the venereal seldom or never produces it." (p. 275.)

I have seen earthy deposits in the absorbent vessels of the skin, and also of the spermatic cord, giving them the appearance of corallines.—J. F. S.]

Inflammation of *Nerves* or rather of their sheaths is no very rare circumstance. As the nerves have but few nutritive vessels, the usual symptoms of inflammation, viz., heat, redness, and swelling, are present only in a slight degree. It begins with formication, torpor, frequently with severe darting pain, which spreads in paroxysms, like electric shocks, along the branches of the nerves; and to these are added febrile excitement, cramps, and convulsions. The inflammation may have either a *chronic* or *acute* course; the former we observe in *ischias nervosa* and many neuralgies, the latter in *tetanus*, *hydrophobia*, and so on. On examination we find the nervous sheaths especially affected, reddened, swollen; the nervous matter is frequently dissolved, as if grangrenous; often there are produced exudations in the nervous sheaths, or degeneration of the nerves.

Inflammation in the *Bones* occurs either in the periosteum or in the medullary membrane, or in the substance of the bone itself. In all these cases the symptoms are different, especially according to the acute or chronic course of the inflammation. In inflammation of the *Periosteum*, (*Periostitis*,) a circumscribed swelling with more or less acute pain is produced by exudation between the bone and the periosteum. If the inflammation do not resolve, it runs on to hardening, gouty thickening, exostosis, into caries, necrosis, and more rarely into fungous degeneration. Inflammation of the *Medullary Membrane* is characterized by deep-seated, gnawing pain, at last the bone itself swells throughout its whole thickness; and, if the inflammation do not resolve, it runs on to closing up of the medullary canal, or suppuration and destruction of the bone from within outwards, in necrosis or fungous degeneration. In inflammation of the *Bone* itself thickening throughout its whole extent (*Hypertrophy*) may occur, with closing of the medullary hole, ulceration, necrosis, and different kinds of degeneration of the bony tissue.

42. The *Prognosis* of inflammation is very various ; it depends specially on its severity and character, on its causes, on the constitution of the subject, and on the parts in which it is situated.

43. The *Treatment* of inflammation generally purposes to effect its resolution, except in certain critical inflammations, in wounds with much contusion, and in furuncles.

The first indication is the removal of the cause, if it continue to operate. If the inflammation be not very great, this alone is often sufficient. If the cause cannot be removed, or the inflammation have advanced to a certain extent, the plan of treatment includes all the means which are implied in the term antiphlogistic mode of cure. In those inflammations which are connected with much fever we must employ bleeding, nitrate of potash, and other antiphlogistic remedies, with cooling diet and rest. If the inflammatory symptoms are thereby diminished, calomel is specially useful to hasten the absorption of the lymph effused into the cellular tissue, and to prevent its coagulation. If the inflammation have an erethitic character, if it be accompanied with greatly increased sensibility, we endeavour after the above-mentioned antiphlogistic treatment to lessen it by opium in connexion with proper antiphlogistic means, such as mercury, hyoscyamus, and hydrocyanic acid, laurel water, and so on. If gastric impurities exist, they must be removed by vomiting and purging. In malignant inflammation the treatment must particularly depend on the kind of accompanying fever; the antiphlogistic treatment is then to be used only with circumspection. If the inflammation have a specific character, if it be connected with a dyscratic affection, we must act according to the degree of the inflammatory reaction, first on the antiphlogistic plan and then against the dyscracy : the antiphlogistic treatment, however, in this case, requires to be pursued with moderation.

[JOHN HUNTER, in treating "of the methods of resolution by constitutional means," makes many very excellent remarks on blood-letting, the object of which, as just mentioned, is to produce the contraction of the vessels, and which is always to go "hand in hand" with the soothing or lessening irritability, or the action of dilatation, by means of sedatives, relaxants, and stimulants, sudorifics, &c. Neither of these proceedings "can possibly lessen the original inflammatory disposition :" they may, however, "in some sense be reckoned direct; for, whatever will produce the action of contraction in the vessels, is counteracting the action of the dilatation. Lessening the power of action belonging to any disposition can only lessen or protract the effects, which, however will be of singular service, as less mischief will be done, and it will often give the disposition time to wear itself out. Means employed on this principle, should be such as give the feel of weakness to the constitution; which will affect the part, and will make the vessels contract; but this practice should not be carried so far as to produce the sense of too much weakness, for then the heart acts with great force and the arteries dilate. Bleeding, then, as a general principle, is to be put in practice: but this must be done with judgment; for I conceive the effects of bleeding to be very extensive. Besides the loss of any quantity of blood being felt, in proportion to the quantity lost, an universal alarm is excited, and a greater contraction of the vessels ensues, than simply in proportion to this quantity, in consequence as it would appear of a sympathetic affection with the part bleeding.

"As many patients that seem to require bleeding have been already bled, it may not be improper to inquire how they bear or are affected by bleeding; for, certainly, all constitutions (independently of every other circumstance) do not bear this evacuation equally, and it is probable, that its effects on inflammation may be nearly in the same proportion; if so, it becomes a very useful caution; for, although the loss of blood may as a general principle be set down as a weakener, and probably the greatest, as we can kill by such means, yet the loss of certain quantities in many constitutions is necessary for health; this is either when there is a disposition to make too much blood, or a constitution that cannot bear the usual quantity; in such, when known, bleeding with freedom is certainly necessary. * * * * * * Every part of the body under inflammation will not bear bleeding alike. I believe that the constitution bears bleeding best when the inflammation is in parts not vital, and those near the source of the circulation: whatever disturbs some of the vital parts, depresses, but not equally in all; and in them it becomes more necessary to be particular, for, in accidents of the brain, bleeding freely, even so as to produce sickness and fainting, is necessary. It is probable that the sickness attending such accidents, is designed to lessen the influx to the head, and occasion the vessels of the brain to contract." (pp. 335, 7.)

"With regard to this evacuation," (blood-letting,) he observes further, "it is worthy of particular consideration, whether or not in all cases, where it can be put in practice, bleeding in or near the part will answer better than taking the blood from the general habit; for certainly less may be removed in this way, so as to have equal effect upon the part inflamed, (and probably upon every disease that is relieved by bleeding,) and yet affect the constitution less; for, although, in many cases, the general habit may be relieved by bleeding, yet the part affected, where it can act, will in all cases require this evacuation most, and local bleeding will keep nearer these proportions, whereas taking blood from the general system is just the reverse. * * * I have observed that there is something similar to sympathetic affection in bleeding. I conceive that all the sympathetic powers, the universal, continued and contiguous, may be brought into action from the local influence of bleeding. Thus, bleeding in the part inflamed, I can conceive, does more than simply emptying the vessels mechanically, for that would soon be restored from the general circulation; but it acts by continued sympathy, viz., the vessels of the part being opened, they contract for their own defence, and this is carried further among the vessels of the part; so that bleeding from the part acts in two ways, viz., mechanically by relieving the vessels of some blood, so as to allow them to contract in proportion as the load is taken off, and also to excite them to contraction in order to prevent the effusion of blood. I suppose, likewise, that contiguous sympathy comes into action; for this would appear from practice and observation to be a principle in bleeding: therefore, in inflammation of contiguous parts it is proper to bleed from the skin opposite to them." (pp. 338, 9.)

"Where the first indication for bleeding takes place, viz., where there is violent inflammation, with strength of constitution, bleeding freely will be of singular service. * * * As it seldom happens that bleeding once will be sufficient in a considerable inflammation, the first or preceding blood taken becomes a symptom of the disease. * * * On the other hand, there may be indications for bleeding sparingly; first, when there is too much action with weakened powers; secondly, when there is a disposition to form but little blood; thirdly, when the part affected is far from the source of the circulation. From the above three dispositions that require bleeding sparingly or with caution, I may observe, that it will most probably be proper in all such cases to bleed from, or as near, the part affected as possible, in order to have the greatest effect with the loss of the least quantity of blood, more so than when the constitution is strong, because the constitution in such cases should feel the loss of blood as little as possible. * * * But in many cases the blood cannot be taken away from the part itself, but only from some neighbouring part, so as to affect the part inflamed." (pp. 339, 40.)

"Bleeding should in all cases be performed with great caution, more particularly at first; and no more taken than appears to be really necessary; it should only be done to ease the constitution, or the part, and rather lower it where the constitution can bear it; but, if the constitution is already below or brought below a certain point, or gives the signs of it from the situation of the disease, then an irritable habit takes place, which is an increased disposition to act without the power to act with. This of itself becomes a cause of the continuance of the original disposition, and therefore will admit neither of resolution nor suppuration, but continue in a state of inflammation, which is a much worse disease than the former." (p. 344.)

44. Different as is the *General* treatment of Inflammation, no less so is the *Local*. The local means are, *abstraction of blood*, *cold*, *moist*, or *dry warmth*, *salves* and *plasters*, *astringent*, *anodyne* and *derivative means.*

["Wherever," says John Hunter, "there has been a violence committed, or some violent action is going on, there is a greater influx of blood to that part. Lessening therefore that influx becomes one mode of relief; for, as the vessels dilate, they should not be encouraged in that action. Although the increased influx is to be considered chiefly as an effect, yet it is to be considered as a secondary cause; and, from our ignorance of the immediate cause, it is probably only through such secondary causes that we can produce any effect; and upon these principles most likely rests, in some measure, the method of resolution; for, whatever will lessen the power and disposition will also lessen the effect; and possibly these will likewise lessen the force of the circulation. If the inflammation is attended with considerable action and power, as it were increasing itself, then the modes of resolution are to be put in practice; the one by producing a contraction of the vessels, the other by soothing or lessening irritability, or the action of dilatation. The first, or contraction of the vessels, is produced in two ways; one by producing weakness, for weakness excites the action of contraction of the vessels; the other by such applications as induce the vessels to contract." (p. 335.)]

45. *Local Bleeding* is more indicated as the inflammation is more simple and active, the redness and swelling greater. Every local blood-letting is connected with a certain degree of irritation which may at once reproduce an increased influx of blood. This is the more certain when general plethora is present. It is therefore necessary in many cases to employ general previously to local bleeding. Local blood-letting is performed by *leeches*, *scarifications*, and *cupping-glasses*. Leeches are most commonly employed; scarifications are restricted to those cases in which the application of leeches is not possible, as, in the mouth, on the tongue, in the throat, on the conjunctiva. Cupping is more especially suited to lingering and deep-seated inflammations, inasmuch as, besides the abstraction of blood, it also operates as a powerful derivative on the surface.

46. The employment of *cold* by the overlaying of cloths dipped in cold water, in water and vinegar, in water cooled by the solution of different salts, in solutions of acetate of lead or sulphate of zinc, the application of ice and snow, is only indicated at the commencent of idiopathic inflammation, when but little swelling has taken place. These means must always be preserved at the same degree of cold. They are specially active in inflammations caused by severe bruises, lacerations, and so on, when there is accompanying weakness of the vessels, and their effect may then be still more increased by the addition of spirituous remedies; for example, brandy, THEDEN's arquebusade, and so on.

[In using ice or freezing mixtures, care must be taken, lest, by their too long continuance, the vitality of the part is destroyed, and sloughing of the skin produced, which has occasionally happened.—J.F.S.]

47. *Moist warm remedies* are employed in shape of fomentations and poultices, which are made of mucilaginous or mealy substances, from linseed-meal, bread crumbs, oatmeal, bran, marshmallow leaves, emollient herbs boiled with water or milk put into linen bags and laid in such way as at once to cover the whole neighbourhood of the inflamed part. Poultices are preferable to fomentations, as their warmth is retained longer, and they need less frequent renewal. Fomentations are therefore only employed in cases where the part is so sensitive that it cannot bear the pressure of the poultice; they must also extend over the whole neighbourhood of the inflamed part, and be covered with a dry towel or flannel by which the heat is longer retained. These remedies are especially applicable to large swellings and painful tensions, as, by their relaxing properties, they diminish the resistance of the cellular tissue. If the tension be less, the poultice may be moistened with lead wash. Many inflammations, as gouty and erysipelatous, do not consort with the employment of moist remedies, but only with *dry warmth*. When the pain is very severe, narcotics, as the fresh hyoscyamus, belladonna, and so on, may be added to the poultices. With these moist warm remedies are usually also employed the

infriction of emollient salves, especially mercurial ointment, in order to further resolution by hastening the absorption.

[" Fomentations, or steams, washes, and poultices," says HUNTER, "are the common applications to a part in the state of inflammation. The first and last are commonly applied to inflammation arising from external violence and proceeding to suppuration; the second commonly to internal surfaces, as the mouth, nose, urethra, vagina, rectum, &c. The action of the first two is but of short duration.

"Fomentations and steams are fluid bodies raised into vapour: they may be either simple or compound; simple, as steam or vapour of water, compound as steam of water impregnated with medicine. * * * * Washes are in general fluid applications, and are more commonly applied to inflammations of internal surfaces, than of the common integuments: there are washes to the eye, called collyria; washes to the mouth and throat, called gargles; washes to the urethra, called injections, and to the rectum, called clysters. * * * These applications, like fomentations, are of short duration, for there is no possibility of applying these powers constantly, except in the form of a poultice, whose operation is somewhat similar, and indeed they are only substitutes for a poultice, where that mode of application cannot be made use of, as I observed with respect to internal surfaces.

"Poultices are constant applications, and like fomentations may be of two kinds, either simply warm and wet or medicated. The greatest effect that a poultice can produce must be immediate; but its power will extend beyond the surface of contact, although only in a secondary degree.

"To the common inflammation, the simplest poultice is supposed to be the best, and that effect I believe is only by keeping the parts easier under the complaint; but I am of opinion that such do not affect the inflammation any other way. A common poultice is, perhaps one of the best applications when we mean to do nothing but to allow nature to perform the cure with much as ease to herself as possible. Poultices may be medicated so as to be adapted to the kind of inflammation." (pp. 361, 362.)

ABERNETHY's observation that "poultices are blessings or curses as they are well or ill made, and that more commonly they only irritate instead of doing good," though it may excite a smile, is borne out by daily observation; for, instead of the highly sensitive surface of an inflamed part being soothed, as it should be by the application of a poultice, "the three properties of which are," to use that excellent teacher's words, "that it should be perfectly soft, perfectly smooth, and perfectly moist," it is too frequently irritated by loading with a heap of hard and lumpy materials which soon dry, and almost as soon become sour.

The *bread and water poultice* is the best, and in general most suited for all circumstances, either as a simple application, or as a vehicle for the employment of the juices of substances which in themselves are too harsh to be applied to very sensitive parts. To make this poultice, ABERNETHY directs:—" Scald out a basin (for you can never make a good poultice unless you have perfectly boiling water) and put boiling water in it; throw in some coarsely crumbled bread crumbs, and cover it up with a plate. When as much water has been soaked up as the bread will imbibe, drain off the rest, and a light pulp (not to be beaten into paste, as usually done, but merely broken with the edge of a fork) is then left, which is to be spread, the third of an inch thick, on folded linen, and applied at the temperature of a warm bath." If it be advisable to medicate the poultice, the juice of fresh hemlock, decoction of carrot, or opium, or any other material in solution, may be added to the sodden bread after it has been well drained; and thus is formed a very soothing application. It is best not to add lard or grease of any kind to a bread poultice, as thereby its relaxing effect on the skin is diminished or destroyed. But as, if left exposed to the air, it soon cools, dries, gets hard, and becomes uncomfortable and irritating, it must be either continually moistened by dropping on it, from a sponge, warm water or the warm medicated solution through the linen, without removing it from the part to which it is applied, and under which circumstances it acts to a certain extent by evaporation, diminishing the increased external heat, and lessening the action of the vessels, though the warmth of the water prevents its reduction to coldness. But, if suppuration have set in and it is necessary to keep up the warmth, then the cloth containing the poultice must be enveloped in a piece of oiled silk, which retains the moisture, and be overlapped with flannel, which preserves the warmth. Milk is often used instead of water for making poultices; but, if the skin be unbroken, water is preferable. No poultice should be boiled, as it is merely converted into paste.

The *linseed-meal poultice* is to be made like the former, by throwing the meal into perfectly boiling water; but it requires well beating to remove all the lumps, and is then to be spread a quarter of an inch thick on linen. It is not a good application for *inflamed parts on account of its weight, and, indeeed, under any circumstances, it is best if made with an equal quantity of bread crumbs.—MS. Notes of Lectures.*

In cases where warmth is most agreeable to the patient's feelings, and in which fomentations are employed, either because thin flannel dipped in them is lighter than the poultice, or because the surface to be covered is so large that a flannel is most convenient, the moisture and warmth are easily preserved by enveloping the overlaying flannel with oiled silk; this treatment has also the advantage of not so repeatedly disturbing the patient as the flannels alone do.—J. F. S.]

48. In the *Torpid* inflammation this character may show itself from the first or during its progress: when the expansion is more passive, and the vessels over distended, with diminished reaction, the congestion of the vessels must first be relieved by local blood-letting, and then the vital activity must be aroused by exciting remedies; by the momentary use of cold, by overlaying with watery or vinous infusions of aromatic herbs, by warm applications of lead wash or THEDEN's arquebusade, by infriction of volatile salves, of mercurial ointment with camphor, by the application of irritating plaisters, of ammoniacum plaister, which we specially use at night, because the applications very readily cool. With these local remedies a corresponding general treatment according to circumstances must be coupled.

The local and general use of stimulating and irritating remedies in many cases of inflammation is not contradictory to the above-mentioned conditions, and does not mislead to the recognition of the so-called *asthenic inflammations.* There is no inflammation depending on weakness; certain states of disease may, however, co-exist with inflammation, or be produced by the consumption of vital activity, caused by the inflammation, by the removal of which alone a cure of the inflammation is possible.

49. The *derivative remedies* are founded on the law of reciprocal action in our constitution; by which means an existing irritation may be lessened or removed by a more severe one. To this class belong blisters, setons, issues, and the rubbing-in of irritating salves. In general these are only to be used when the severity of the inflammation has been moderated by the preceding treatment; they are particularly useful in chronic inflammation.

In how far this general mode of treating inflammation must be modified according to the difference of the structure affected, will be subsequently considered in many places.

["Derivation" says HUNTER, "means a cessation of action in one part, in consequence of an action having taken place in another: and when this is a cessation of a diseased action, then a cure of that action in the original part may be said to be performed: this cure was brought into use from the idea of humors; that is, the drawing off of the humors from the seat where they had taken possession: but I believe much more has been ascribed to it than it deserves. How far it really takes place, I have not been able fully to ascertain in all its parts; that is, how far the real disease has been invited, and accepts of the invitation: but I have already observed that there is such a principle of disease in the animal economy, although we must see from derivation, that the same quantity or perhaps more irritation is retained in the constitution; yet the artificial irritation produced being either such as more readily admits of a cure than the diseased part, or being in parts which are not so essential to life, an advantage by this means is gained." (p. 359.)]

50. If the inflammation have a disposition to recede, every thing must be removed from the inflamed part which can disturb the proper development of the inflammation and favour its recession. The inflamed part must be covered with warm flannel, it must be protected from the approach of the air, and medicines given internally which will act on the skin. If the inflammation have already subsided from the external surface, we must

endeavour to bring it back by mustard plasters, blisters, and cauteries; it must be treated generally according to the severity and character of the inflammation.

51. If the inflammation have run on to exudation, and inflammatory symptoms still remain, antiphlogistic neutral salts must be employed, especially bitartrate of potash; but, if accompanied with weakness and inactivity of the absorbents, then exciting remedies and such as act upon the kidneys must be used, as mercury, squills, digitalis, senega, and so on. If the accumulation be so great that it interferes with the active functions of important viscera, or cannot be removed by the methods already proposed, the fluid must be discharged by opening the cavity in which it is contained. In œdematous swelling of the cellular tissue, bags of warm aromatic herbs, mingled with camphor, must be used; in torpid subjects, flannel fumigated with mastic and amber, and a moderate compression by means of bandages may be employed.

52. If the symptoms described (*par.* 10) indicate a transition of the inflammation to suppuration, nature must be assisted in this process. In strong persons, and with a certain degree of inflammation, suppuration in general is effected without difficulty, and it is sufficient to employ a less active general treatment, emollient fomentations and poultices. If the pain be more severe, narcotic poultices may be used; and, in decided hardness and inflammation, even blood-letting. But if, on account of the weakness of the constitution, or the torpid character of the inflammation, the formation of pus is tedious, it must be assisted by stimulating remedies; roasted onions, yeast, must be mixed with the poultices and applied warm. The diseased parts must be covered with rye flour and honey, with *emplast. de cicutâ c. ammoniaco, emp. galb., emp. diachylon comp.* All these, however, may be dispensed with by the suitable and constant application of warm lotions and poultices.

53. When under this treatment of abscess its *ripening* has taken place, that is, if about its circumference hardness is no longer to be felt, it either opens of itself or it must be opened. Only in small abscesses just beneath the skin, and in those in glandular structures, may the opening be left to nature (1). The early opening of abscesses is not unfrequently required, and specially under the following circumstances: 1. if in sensitive parts severe pain arises from the collection of pus, and the tissue of the part is thereby rendered tough and unyielding; 2. if the pus be collected beneath muscles and firm aponeuroses, in which case its burrowing is to be dreaded; 3. in abscesses in the neighbourhood of important organs surrounded with loose cellular tissue; for instance, abscesses in the neighbourhood of the rectum, or in the neck, where the pus may spread to the collar-bones; 4. in abscesses on the joints, or in the neighbourhood of other cavities, where, however, bursting into these cavities is not so much to be feared as the symptoms resulting from the pressure of the pus; 5. if the suppuration be near a bone or a tendon; 6. if by long continuance of the inflammation the cellular tissue beneath the skin be destroyed to a considerable extent; 7. and in critical abscess.

Abscesses in the neighbourhood of important parts are generally opened rather late, because in a large collection of pus the elevation of the skin ensures against any injury to deep-seated parts.

[(1) This is not good practice; abscesses just beneath the skin should always be punctured early, as otherwise there is great risk of sloughing of the integument and the formation of an ugly scar. Neither should abscesses in glands be left to burst, which is often a very tedious process, as the capsule of the gland does not readily ulcerate, and will not till the whole, or nearly the whole, gland is destroyed; a large cavity is thus formed, which is generally very difficult to heal, as it assumes oftentimes a fistulous character. It is therefore always best to puncture a glandular abscess as soon as the capsule and the skin have become adherent, and the angry appearance of the latter indicates its disposition to ulcerate. But it is not unfrequently advisable to open such abscesses before the skin reddens, or even before it is adherent; for, in scrofulous and chronic abscesses, there is often little and sometimes no redness of the skin, and yet, the collection of pus increasing, the skin becomes stretched beyond endurance, and sloughing ensues.—J. F. S.]

54. The *opening of abscesses (Oncotomia)* is effected either by a *cutting instrument*, by *escharotics*, or by *seton*. That point is preferred for opening where the fluctuation is most distinct and the skin thinnest; but, if the skin is everywhere equally thin, then the lowest part is preferred. The size of the opening depends on the extent of the abscess, and should always be such that the pus will flow without hinderance. An aperture of five to eight lines long is generally sufficient; an opening of an inch and a half must be the extreme for an abscess of large size. It must be recollected, however, that the skin, distended by the pus, will contract after its evacuation, and thereby the aperture will be rendered smaller than was intended.

55. The *cutting instrument* is used in the following manner: the blade of the *lancet* being held with the finger and thumb of the right hand, sufficiently far from the point to permit of its entrance into the cavity of the abscess, and the skin covering the abscess being stretched by the fingers of the left hand, the lancet is to be thrust perpendicularly or obliquely in till the pus, oozing up by its sides, shows that the cavity of the abscess has been opened; and the aperture is to be increased to a proper size by raising the point of the lancet as it is withdrawn.

If the abscess be deep and the coverings thick, it should be opened with a *bistoury*, which, being held like a pen, is to be thrust into the abscess in the direction of the muscular fibres, and the opening is to be enlarged on bringing it out. If the abscess be very deep, and in the neighbourhood of important parts, it is most advisable to divide the parts covering it by repeated cuts, and with the fore finger of the left hand to feel in the wound at which point the fluctuation is most perceptible. This precaution is specially to be recommended in deep abscesses of the coverings of the belly and chest.

After opening an abscess the pus must be allowed to flow out gradually of itself, or it may be assisted by gentle pressure; everything which can interfere with its escape must be avoided, the aperture of the abscesses should not by any means be stopped up, but only covered lightly with charpie and a warm moist poultice, or merely with the latter.

[Pressing and squeezing abscesses, for the purpose of emptying after they have been punctured cannot be too much deprecated. Unnecessary pain is inflicted on the patient by the rough handling, which bruises the distended and still inflamed walls of the abscess. One object in making the puncture is to relieve the tension of the adjacent parts, and the escape of a very small quantity of pus immediately effects this. But the abscess empties itself sufficiently quickly by the simple contractibility of the skin, which gently presses out the fluid contents with little or no pain to the patient.

It not unfrequently happens that if the walls of the abscess be thick, the clean cut edges of the puncture are found adherent, and the aperture closed within twenty-four hours. The adhesions, however, are easily broken through, and the opening re-established by a little gentle pressure on the abscess. But I think it preferable, after making the puncture, to introduce between the lips of the wound a very small portion of lint, with a long end hanging out: this is to be removed when the first poultice is replaced a few hours after making the puncture, which by that time is sufficiently established.—J. F. S.]

56. *Escharotics* are employed in the following manner: a piece of linen spread with sticking plaster, and in which a properly shaped hole has been cut, is to be so laid upon the abscess that the aperture should correspond with the point where it is intended to be emptied. The hole in the plaister is then to be filled with bruised and moistened caustic, and covered with sticking plaster. After six or eight hours the plaister is to be removed, if the caustic have produced a good slough, or the walls of the abscess have been eaten through and the pus escaped. The slough is to be pierced with a lancet and the abscess emptied, or, if the emptying does not seem urgent, the slough may be allowed to separate, and then the lancet is to be introduced. The pus is to be discharged by moderate pressure in an unbroken stream, the aperture to be covered with sticking plaster and a bandage applied. The walls of the abscess frequently at once unite, but most commonly a smaller quantity of pus collects, the emptying of which is to be performed by a second puncture, and the union furthered by a compressing bandage.

57. In passing a *seton* through an abscess an aperture with a lancet is to be made at its upper part, through which a blunt probe, armed with a bundle of several cotton threads some yards long is to be passed to the very bottom of the abscess, till its extremity is felt against the skin. An assistant retains the probe in this situation, and the skin being rendered tense, a cut is made upon the probe, which is then to be drawn out and the seton introduced into the cavity of the abscess. This may be done with a seton needle, in which case the parts covering the abscess are to be raised into a fold and then transfixed with the needle. When the abscess is emptied, the opening is to be covered with charpie and sticking plaster, the seton thread fastened, the whole covered with a compress and supported with a proper bandage. A fresh portion of the thread is to be drawn in daily. When the suppuration has diminished the threads are to be withdrawn and the union of the walls promoted by regulated pressure. In many cases the seton may be removed in three or four days, if the walls of the abscess have acquired a sufficient degree of inflammation to unite by proper pressure.

58. In general the opening of abscesses with a cutting instrument is most preferable. The application of escharotics is accompanied with great pain; a part of the skin is always destroyed, in consequence of which a large scar remains. The seton is also painful and excites more or less severe inflammation. These modes of opening are therefore restricted to those cases in which it is desirable to excite a certain degree of inflammation, as will be presently mentioned in speaking of cold abscess. The employment of caustic in critical abscesses, in order to hasten and bring about their opening at an earlier period, may be conveniently replaced by the proper use of poultices, and the ordinary method of opening with the lancet.

[Puncturing abscesses is in all cases to be preferred. Escharotics are never permissible, as they produce a certain slough, the prevention of which is one object in emptying an abscess. The introduction of a seton is almost as objectionable; for the inflammation of the sac of the abscess which it excites will often be uncontrollable and hasten hectic fever.—J. F. S.]

59. The so-called *Cold Abscess* (Lymph-Abscess) resulting from lingering inflammation, (*par.* 15,) in which the covering skin is but little or not at all changed, may sometimes be dispersed by resolving poultices, infrictions, and plasters, by producing artificial wounds in the neighbourhood, by the application of the moxa, and so on, with simultaneous attention to the constitutional disorder. This, however, seldom happens, and since, after they have been opened in the way of ordinary abscesses, or have opened of themselves in consequence of the diminished vital activity of their walls, and the generally depressed state of the system, a very ill-conditioned and frequently fatal thin and copious suppuration sets in, special modes of proceeding in the treatment of these abscesses are therefore directed, in order partly to prevent the entrance of the air in opening them, partly to excite by the emptying of the swelling, such degree of inflammation as will produce their union, or the secretion of a good plastic pus, and then the cure is effected as in common abscess.

60. The modes of treatment to this end are, the emptying of the swelling with a lancet puncture or with a trochar, without admitting air, after which the opening is to be closed with sticking plaster, a moderately compressing bandage applied, and the opening frequently remade, till the union of the walls of the abscess has taken place (ABERNETHY ;) opening with the lancet after the previous application of caustic (BEINL ;) the introduction of a seton or a bundle of silk threads, to be withdrawn on the third or fourth day, and the cure then perfected by compression (WALTHER ;) tapping with the trochar and injection of red wine, solution of bichloride of mercury, or of nitrate of silver (SCHAACK ;) or of boiling hot water (RUST ;) or a solution of fully neutralized nitrate of mercury (NASSE ;) the laying open of the swelling longitudinally throughout half its length, and filling it with charpie moistened with solutions of caustic (ZANG ;) and the removal of the skin from the whole extent of the swelling (CALLISEN.)

61. The variety of these modes of treatment proves, that neither of them separately taken is sufficient to meet our wishes. The choice of them must therefore be guided by the difference of constitution, by the more or less weak state of the cellular walls and by the size of the swelling. If the tumour be not be very large and the constitution of the patient still tolerably good, perfect closing of the cavity of the abscess may usually be produced by repeated puncture with the lancet or trochar, or at least it may be so much diminished that we may be able to effect a cure by laying it open with a bistoury, and filling it with charpie, moistened with irritating remedies, especially solution of nitrate of mercury. In swellings of larger size it is far preferable to make the opening with caustic, or by the introduction of a seton. If the cure be not in this way effected, and, if suppuration threatening exhaustion occur after artificial or spontaneous opening, it is proper to remove from the front wall of the swelling as much as may be allowable, or to fill the whole cavity with charpie, which, according to the various degrees of irritating, is to be moistened with a stronger or weaker solution of nitrate of silver, or nitrate of mercury, to bring about a good suppuration. I am, however, convinced, that by the employment of these violent modes of treatment, the very worst symptoms are often produced which are dreaded in the common mode of treating abscesses. At least, I have in very many cases of cold abscess made the opening at the proper spot in the usual

way with the lancet, and, without the use of any other local means than moist warm poultices, the cure has been effected more quickly and with less trouble than by other modes of treatment. The opinions relative to the treatment of this cold or lymphatic abscess are so various, doubtless because they are confounded with *congestive abscess* and with the swellings of mucous bags (*par.* 17.) Corresponding general means must be employed with the local treatment; we must use strengthening remedies bark, rhatany, sweet flag, with diluted acids, a strong nourishing diet, and attention must be paid to cleanliness and good air.

According to Kluge (*a*), the lymph should be discharged by an incision, or, if that be not sufficient, the whole front wall of the swelling must be cut away, the opening of the hardened lymphatic vessel must be found, which is usually superficial and easily discernible by the trickling of the lymph; a bristle must be introduced into its open mouth, and then the vessel must be slit up for half an inch or an inch, until the healthy trunk is reached. The bristle is then to be removed, and either a compressing bandage applied, or, if there do not occur a proper degree of inflammation, the opened lymph-vessel must be touched along the part which has been slit open with a pointed piece of nitrate of silver up to the healthy portion, and then the compress applied.

Upon the subject of opening abscesses consult

62. The further treatment after opening an abscess must be quite simple; *we must endeavour to keep up merely a free undisturbed escape of pus, and to preserve a proper vital correspondence.* No further local treatment is required beyond the use of moist warm poultices. The edges of the opening draw together, the walls of the abscess approach and adhere, granulations (*Fleischwarzen*, Germ.) are produced from the bottom of the abscess by the development of fine vessels and delicate cellular tissue, which become more and more solid, are covered with a thin skin, and form a scar (*Cicatrix*, Lat.; *Narbe*, Germ.; *Cicatrice*, Fr.) A more active degree of inflammation, when continued or developed after the opening of the abscess, in consequence of which its edges swell, its neighbourhood becomes very sensitive, and the suppuration diminished, is usually consequent on improper treatment, on the use of tents and so on, and can only be relieved by the aforesaid treatment, which diminishes the irritation.

63. If a proper degree of vitality be wanting in weak constitutions or in abscesses in parts far distant from the heart; if the edges of the

---

(*a*) Zembsch, as above.

abscess be flabby, insensible, discoloured; if a thin lymphatic sanious fluid be secreted; these are indications for the employment of more or less stimulating remedies, the *ung. digestivum basilicum*, the oil of turpentine, decoction of oak bark, bark with tincture of myrrh, filling the cavity of the abscess with charpie, strong solution of nitrate of silver, with which is to be moistened the charpie laid in the cavity of the abscess. But all these means are superfluous; the moist warm poultices are more effectual in raising the vital activity necessary for the secretion of good pus, the pus thereby more readily escapes, and the patient is saved from the troublesome and painful dressings by the sticking of the bandages. If the patient's strength fail and general weakness ensue, strengthening remedies, bark, rhatany, sweet flag, good nourishment, the enjoyment of pure air, and so on, are indicated.

64. If the edges of the abscess-aperture unite, whilst the secretion of pus continues, they may be easily drawn asunder or separated with a probe. Should the opening become too small, so that the pus cannot escape freely, it must be enlarged with the knife. If the granulations are developed too strongly, the *proud flesh (Caro luxurians*, Lat.; *Wucherndes Fleisch*, Germ.*)* must be touched with nitrate of silver and a compressing bandage applied, by which cicatrization is specially encouraged.

65. When the pus does not escape properly, but collects in the abscess, (which may depend on the opening being too small or upon some peculiar situation of the abscess,) it sinks down in consequence of its own weight, or the little opposition which the loose cellular tissue in the interspaces of the part offers to it, or the suppurative process may extend with failure of the adhesive inflammation, and, on the other hand, an ulcerative absorption may favour the extension of the abscess, and form cavities or canals which are called *fistulous passages (sinus fistulosi.)* These fistulous passages are often consequent on improper treatment, if the opening of the abscess be stopped by plugs, and so on, and the due flowing of the pus thereby prevented. Under these circumstances a much larger quantity of pus escapes from the abscess than from its size might be expected; especially if its neighbourhood be pressed in different directions; examination with the probe gives certain knowledge of its extent. If such fistulous passages remain long, their walls are overspread with a soft fungous membrane, similar to mucous membrane, which prevents the healing, and, when still longer continued, assumes a whitish, hard, callous condition.

The membrane of the fistula first pointed out by HUNTER, has been well described by VILLERMÉ (*a*), LAENNEC, and BRESCHET (*b*).

[The passage in HUNTER here alluded to is the following:—"When the parts are unsound, and of course the granulations formed upon them unsound, we have not this disposition for union, but a smooth surface is formed, somewhat similar to many natural internal surfaces of the body, and such as have no tendency to granulate, which continues to secrete a matter expressive of the sore which it lubricates, and in some measure prevents the union of the granulations. I imagine, for instance, that the internal surface of a fistulous ulcer is in some degree similar to the inner surface of the urethra, when it is forming the discharge commonly called a gleet. Such sores have therefore no disposition in their granulations to unite, and nothing can produce an union between them but altering the disposition of these granulations by exciting a considerable inflammation, and probably ulceration, so as to form new granulations, and by these means give them a chance of falling into a sound state." (p. 480.)]

(*a*) In Journal de Médecine, par LE ROUX, July, 1815.

(*b*) Dictionnaire des Sciences Médicales, vol. viii. p. 206. Journal von GRAEFE und WALTHER, vol. ii. part iv.

66. These fistulous passages may be generally avoided by the treatment already mentioned. If the fistulous passage be still recent, the free escape of the pus may be effected by a suitable enlarging of the opening, by the entire division of the fistulous passage, if it be superficial; or, if the bottom of the passage be near the skin, by means of a counter opening; for the latter purpose a probe is introduced, with which the bottom of the passage and the skin above it are raised, and then the probe is to be cut upon. The further treatment is to be according to the preceding rules. In still longer continued fistulous passages, especially when their walls have become callous, we endeavour to excite a proper degree of inflammation of the walls of the passage, usually by the introduction of a seton, or of a bundle composed of many threads, which is tied together externally upon the fistulous passage, and daily drawn tighter (**Langenbeck**) (*a*), or by the injection of irritating fluids (H. **Dewar**) (*b*); for instance, a solution of nitrate of silver, of bichloride, or nitrate of quicksilver, or by the introduction of a bougie, the point of which has been smeared with powdered nitrate of silver (**Cramer**) (*c*), (von **Walther**) (*d*), and so on, and then, by a regulated pressure throughout its whole extent, to produce union of its walls. Where a satisfactory dilatation of the fistulous passage is possible, the cure may be effected without these painful remedies by the careful avoidance of any bandage which might interfere with the escape of the pus, and by close attention to the before-mentioned rules.

According to **Langenbeck**, the introduction of a ligature is, in many cases, preferable to incision, which oftentimes is impracticable without injuring large vessels, and so on. By the ligature inflammation is produced, the surface of the abscess becomes red and painful, the secretion of ichorous fluid is diminished, good consistent pus and near the ligature shooting healthy granulations are produced, and the skin becomes more firm and solid. As these symptoms come on, the ligature is to be gradually drawn tighter. In common cases, the ligature requires to be used only from four to eight days, to produce its effects. If it should be necessary to cut through the wall of the fistulous passage with the ligature, the remaining cavity must be filled with charpie.

67. During suppuration the practitioner must pay especial attention to the condition of the digestive organs; for impurities in the intestinal canal are frequently the cause of unhealthy pus; neither must pure healthy air be forgotten.

If the suppuration be continued on account of any dyscracy, the proper means for its counteraction must be employed.

On the treatment of abscess compare

von **Kern**, Annalen der chirurgischen Klinik zu Wien, vol. i. 1807, vol. ii. 1809.

von **Walther**, über die topische Behandlung und über den Verband der eiternden Wunden, der Abscesse, Geschwüre und Fisteln, in Journal für Chirurgie und Augenheilkunde, vol. ix. part ii.

68. The treatment of the Hardening into which inflammation has subsided has a double object, viz. its *dispersion* or its *removal with the knife.* The resolution of the hardening is only possible when the lymph poured into the cellular tissue has not yet consolidated the walls of the part with each other, and its natural structure is not yet entirely lost; consequently, when the *induration is still recent and not very hard.* If there be also decided dyscracy, the curative treatment must be first directed to it.

(*b*) On the Treatment of Sinuous Ulcers; in Medico-Chirurgical Transactions, vol. vii. p. 487.

(*c*) Beitrage zur Heilung der Fisteln und Geschwüre; in Heidelberger clinischen Annalen, vol. x. part i. p. 71.

(*d*) Über Hohlgeschwüre und Fisteln; in Journal von **Graefe** und **Walther**, vol. v. p. 1.

For the resolution of hardening it is usual to employ the *saponaria*, the *taraxacum*, *gramen*; the *gummi ammoniacum*, *galbanum*; *cicuta*, *belladonna*, cherry-laurel water, various preparations of mercury and antimony; the soaps, alkalies and so on: for external use, warm bathing especially with or without alkalies, infriction of volatile salves, mercurial ointment; various plasters, the *empl. de cicutâ c. ammoniaco*, *de mercurio c. camphorâ* and so on; fomentations of narcotic plants; electricity, and galvanism. The repeated application of leeches, the internal and external use of mercury, and iodine, the employment of derivative remedies, with a better regulated and rather strict mode of living, act most satisfactorily.

69. These means must be used with discretion, and not pursued too long, because, otherwise, the general health will be much disturbed or inflammation and transition of the hardening into other kinds of disorganization, or even into cancer, may be produced. When, therefore, resolution is not effected, or when it cannot be attempted, it is most advisable to remove the hardened parts with the knife. If the patient will not submit to the operation, the hardening must be protected as much as possible from external influences; it must be kept warm, attention must be paid to the secretions and excretions; the patient must live regularly, and specially preserve himself from all depressing emotions of the mind.

70. Gangrene is always the loss of vital activity in some part; but the variety of its causes and of the circumstances connected with it render very different kinds of treatment necessary, *in order to stop the further spreading of the gangrene, to assist nature in throwing off the gangrenous part, and to prevent the operation of the gangrenous juices acting upon other parts of the body.*

71. Gangrene may be specially connected with inflammatory, nervous, or gastric fever, with general debility or increased sensibility and convulsions.

When it is consequent on active inflammation and accompanied with inflammatory fever, which is specially the case in young strong persons after external injury and so on, a moderating antiphlogistic treatment can only be employed, and emollient poultices to hasten the throwing off the gangrene. If the gangrene arise from the confinement of the inflamed parts by unyielding aponeuroses, the removal of these mechanical hinderances, by suitably deep and extensive incisions, can alone prevent the production or further spreading of the gangrene.

In most cases the gangrene is connected with general debility, nervous or putrid fever, and then especially is indicated the use of bark with valerian, arnica; serpentaria, fluid hartshorn, diluted acids; naphtha, wine, and so on; if there be putrid symptoms, bark with mineral acids and alum. It must not be forgotten, however, that not unfrequently, under these circumstances, wine and animal food decidedly increase the febrile heat, the pulse becomes quicker, the tongue coated, and the patient very uneasy. A less irritating diet, and only so much mild, nourishing, and farinaceous food as the appetite requires and the stomach can bear, is then more proper.

Not unfrequently in gangrene there is a loaded state of the bowels, which must be as early as possible removed, and then the strengthening remedies employed. In greatly increased sensibility and convulsions, opium, musk, fluid alkalies, and other antispasmodic means are to be used.

72. The *Local Treatment* of gangrene has the two-fold purpose of supporting nature in throwing off the slough and in diminishing the dangerous operation of the gangrenous juices.

If the gangrene be connected with active inflammation, softening, and in very severe pain, soothing poultices are to be used; but, if the gangrenous part be free from pain and shrivelled, stimulating remedies are required, in order to excite suppuration on the boundary of the slough; with which object it is most advisable to use warm aromatic poultices.

The remedies which prevent the influence of the gangrenous juices, by absorbing or decomposing them, are quinine, oak or chestnut bark, camomile, vinegar, wine, brandy, camphor, hydrochlorate of ammonia, turpentine, diluted mineral acids, pyroligneous acid, carbonic acid, effervescing fluids, powdered charcoal. In moist gangrene, these substances are better used in powder, but in dry gangrene fomentations or poultices. In all cases the stench is best diminished by the employment of aromatic or simply moist warm poultices, and by suitable cleansing at each time of their renewal. It is still further lessened by the very useful strewing of powder, which, by its partial drying, often directly prevents the outflowing of the gangrenous juices.

The operation of these remedies may be promoted by scarification or cutting into the gangrenous parts. The scarifications must not, however, penetrate into the living part, or they will favour the action of the gangrenous juice, accelerate the increase of the gangrene and cause dangerous bleeding; their principal object must be *to prevent the collection of the gangrenous juices.* In the gangrene of old people (*gangræna senilis*) scarifications are always dangerous; so long as the toes are still attached at some parts, they must not be removed.

73. The sloughs having been thrown off by this treatment, the remaining wound must be managed according to the rules laid down for treating abscesses, and the vital activity of the patient must be supported by the suitable employment of bark and a nourishing strengthening diet.

74. In most cases nature, after the gangrene is defined, throws off the gangrenous part, and *amputation is not required.* Amputation *is not applicable* in gangrene depending on an internal cause which is still in operation; for, in such case, after the performance of amputation, gangrene again takes place in the wound. But when the gangrene has affected the whole thickness of a limb, and is defined, and the separation of the dead part cannot be expected; or, when produced by external violence, it is proceeding, but the causes of the gangrene can be removed with the gangrenous part, amputation is to be considered as necessary and likely to save life (1). It is, however, here to be borne in mind that gangrene in the deeper parts commonly makes further progress than the external appearance indicates. The amputation must always be performed in the healthy part.

(1) Such is the opinion of Larrey (*a*); but the opposite is especially supported by Pott.

When the gangrene remains stationary, the greatest danger is over. However desirable it may be to relieve the patient of the mortified part, yet in many cases is he unable to bear the shock of the operation. Here, then, in combination with a treatment suited to the diseased condition of the patient, it is more advisable, if the soft parts are divided down to the bone, to saw the latter through below the limits of the healthy part. Diseased condition of the remaining ulcerated surface, may at a subsequent period render amputation necessary.

[So far as my experience is concerned, I believe that amputation should on no account ever be performed, so long as the gangrene is in progress, whatever be its cause;

(*a*) Mémoires de Chirurgie Militaire, vol. iii. p. 142.

for, if it be, the same action will be set up in the stump, and the patient's condition rendered worse by the shock of the operation. Only when the gangrene is proved to have stopped, by the line of separation having descended to some depth in the soft parts, is amputation to be entertained.—J. F. S.]

75. The treatment of *senile gangrene* must depend on the different modes in which it has arisen (*par.* 26.) When livid redness and swelling set in as a consequence of injury, or any other locally operating mischief, softening, soothing, or dry aromatic compositions must be applied, according to the circumstances; in more active inflammation, and in robust persons, leeches should be used. It is proper to allude to these cases, and especially when occurring in plethoric subjects, as DUPUYTREN (*a*), by the employment of the antiphlogistic method, by bleeding and leeching, professes to have met with successful results. The general treatment must correspond with the local; in very severe pain opium in considerable doses should be given (*b*), and, according to circumstances, with tonic medicines. In the other kind of senile gangrene, which comes on with blackening and shrivelling of the part, tonic means in combination with volatile applications with the addition of opium if there be pain, and the local employment of soothing poultices, can alone produce the limiting and throwing off the slough, and respite life for some time.

I have communicated (*c*) an interesting example of senile gangrene of the hand and fore arm, in a woman of eighty-two years of age, in which by proper support of the powers separation of the slough and healing ensued. Compare also HEIM (*d*).

76. Gangrene from pressure by lying is to be guarded against by suitable preparation of the bed, by lying on a mattress instead of a feather-bed, by proper cleanliness, frequent change of the body-linen and sheets, repeated alteration of position, by putting doe-skin beneath the patient, by frequent washing the compressed parts with cold water, lead wash and camphorated spirit. If the part have become red, it must be laid on a hollow formed by introduction of ring-shaped pads, little bolsters of horsehair, cleft mattresses, and afterwards compresses moistened with lead wash, vinegar, or THEDEN's arquebusade water must be applied, or the part must frequently be smeared with an ointment of white of egg and camphor beaten to a cream. When ulcerative absorption has occurred, softening poultices, ointment of oxide of zinc, or of lead, with opium or camphor, should be applied, and, if the ulceration be spreading and deep, aromatic poultices. If actual gangrene be present, then the ordinary treatment for gangrene must be employed. Of course the treatment of the patient's health should be guided by the state of the disease.

In many cases where it is difficult to move the patient, the application of local means may be assisted by the use of LECAT's suspending mat (*e*), or LEYDIG's (*f*) apparatus for raising invalids.

77. In gangrene after the use of cockspurred rye, vomiting and purging must be had recourse to, and subsequently both internal and external stimulating remedies. In many cases amputation has been performed, which, however, has not always been of service, because, especially in patients who had been much weakened, the same changes took place in the stump. If the gangrene has become defined, it is most

advisable to leave the separation of the parts to nature and saw off the bone.

Full reports of observations on this subject are to be found in THOMSON (*a*) and in SAMUEL COOPER (*b*).

78. The treatment of *malignant pustule* varies according to the accompanying symptoms. The local treatment consists in cutting out the pustule by a circular incision, and afterwards cauterizing the edges of the wound with nitrate of silver or sulphuric acid, (also with the actual cautery,) and placing upon it charpie moistened with oxymuriatic acid. The slough is to be covered with a softening bran poultice, and, after it is thrown off, the treatment of the wound is to be simple. If the pustule be not deep, but the slough much outspread, it is proper to make deep scarifications and employ the remedies just mentioned. If general symptoms are not present, it is only necessary to use sulphuric acid or HALLER's acid mixed as a drink. If there be indications of gastric impurities, emetics must be employed in divided but sufficiently effectual doses, and, if they do not operate, purging, or vinegar clysters must be used. If the powers sink and nervous symptoms appear, strengthening and stimulating medicines are required; bark, serpentaria, arnica, valerian with elixir of vitriol, hydrochloric acid, and so on. But bleeding is rarely required, unless in decided plethora and great determination of blood to the head and chest.

79. It is apparent, from the nature of the causes of *hospital gangrene*, already mentioned in what way this dangerous complication of wounds and ulcers can be guarded against. Care must be taken as much as possible for purity of air and proper diet with a moderate use of wine; the greatest cleanliness of the bandages must be observed, the wound must be washed with a light aromatic infusion or with diluted alkaline solutions, and symptoms of gastric impurity must be removed by vomiting and purging. Emetics are especially advised by POUTEAU, DUSSAUSOY, and others, as the most important remedies at the beginning of the disease. They recommend them as being of themselves capable of stopping the advance of the disease.

If the peculiar changes occur in the wound or in the sore, (*par.* 35,) washing the whole surface with good vinegar, after thoroughly cleansing with charpie, and frequently moistening the bandage with vinegar, is often sufficient at the onset to restore the wounds in a few days to their former condition. For the same purpose also is the solution of arsenic recom-

---

(*a*) As above, p. 538.

(*b*) Dictionary of Surgery, article Mortification.

mended. If the surface of the wound do not improve in appearance, its entire extent should be touched with nitrate of silver, or conical pieces of caustic laid in the viscid mass. But, under these circumstances, the most important remedy is the free application of the actual cautery to the whole surface of the ulcerated part. The slough is to be covered with powdered bark and turpentine or some stimulating salve, and when the slough has separated, the appearance of the wound must determine whether the application of the cautery is to be repeated or not. Besides these means, the following may also be recommended ; decoction of bark, diluted mineral acids, especially hydrochloric acid, yeast poultices, spirituous lotions, brandy and myrrh, aloes and camphor, hydrochlorate of ammonia with water and vinegar, *spir. terebinth*, *ung. styrac.* and *Egyptiacum*, balsam of copaiva, solutions of bichloride of mercury and nitrate of silver, butyr of antimony, pyroligneous acid, lemon juice and so on.

80. General treatment, suited to the different condition of the patient, must also be connected with this local treatment. At the onset, if symptoms of irritation and active febrile excitement are present, acid drinks, especially dilute mineral acids, are serviceable ; in impurities of the stomach, emetics ; in great weakness, bark and other tonic remedies ; only in rare cases is a strict antiphilogistic plan of treatment called for. The diet must of course correspond with the general treatment, and care should be taken for purity of air and keeping the patient apart from others.

81. Under the terms *Erysipelas*, *St. Anthony's Fire*, (*Rosa*, *Erysipelas*, Lat.; *Rose* oder *Rothlauf*, Germ.; *Erysipèle*, Fr.,) is usually understood an inflammation of the lymphatic vascular network overspreading the surface of the cutis, in which, not unfrequently, the skin, glands, and Malpighian mucous net, but more rarely the cellular tissue and muscles lying beneath, partiticipate. Under this general notion are included a number of diseased conditions which are considered as modifications of erysipelas, but in their nature are entirely different from it. RUST has the merit of having pointed out their special points of difference, and recognises a *True Erysipelas* (*Erysipelas verum* seu *exanthematicum*, Lat.; *ächte Rose*, Germ.) and a *False Erysipelas* (*Erysipelas spurium* seu *Pseudo-Erysipelas*, Lat.; *unächte Rose*, Germ.)

[HUNTER long since observed, that "most inflammations that are not of the true adhesive and suppurative kinds are called erysipelatous, although, probably, they do not in the least belong to it." (p. 269.) And CHELIUS has echoed him in the above observation, that "a number of diseased conditions, which are considered as modifications of erysipelas, in their nature are entirely different from it." But he has not at all, by his arrangement, mended the matter, and I have, therefore, pointed out, first, the different applications of the terms erysipelas and erythema, which are employed by him very contrarily to our ordinary usage of them; and, afterwards, I have shown that one of his forms of erythema is really that important disease, inflammation of the cellular tissue, which, by other writers as well as by him, is confounded with inflammation of the skin, and often mentioned as gangrenous erysipelas. It is, however, right to observe that our author has, at the end of paragraph 83, shown that he is not unaware of the impropriety of considering this disease as an affection of the skin.—J. F. S.]

82. The *True Erysipelas* appears without any local disposition to disease, but with previous general indisposition, which is usually shown by

weakness and heaviness of the limbs, listlessness, pain in the region of the stomach, loaded tongue, nasty taste in the mouth, disposition to vomit, more or less active fever, head-ache, wandering, lethargy, or madness,—as a pale uncircumscribed redness of the skin, fading into yellowish, which spreads unequally, is shaded off towards the edge, disappears on pressure with the finger, but returns when the pressure is removed. After the appearance of the erysipelas the fever generally diminishes or disappears; but every fresh attack is accompanied with fever. The seat of this erysipelas never extends beyond the lymphatic-vascular net overspreading the surface of the cutis. The severity of the disease is as various as is the condition of the part first attacked; it, however, usually subsides under critical discharges of perspiration and urine, and with scaling of the skin; it never runs into suppuration, but only, with weakly constitutions and other concurrent circumstances, into ulceration and gangrene, in consesequence of which the destruction of the surface of the body extends to the parts beneath, and there ensues, not a bounded fluctuating abscess, but an open, wide-spreading, putrid, ulcerating surface. If the scaling of the skin, critically following the erysipelas, be disturbed by moist remedies, by cold and so on, dropsical swelling ensues. This erysipelas is very fugitive; it subsides of itself; but more commonly after the external use of moist remedies, of cold, or on mental emotions, and so on, it suddenly quits the surface, and causes inflammation of the brain, chest, or belly, madness, convulsions, paralysis, and so on. The true causes of this erysipelas are biliary irritation, disturbance of the functions of the liver, collections of gastric impurities, use of indigestible food, obstruction in the portal system, and a prevalence of peculiar atmosphere and temperature, in consequence of which it seems to be commonly epidemic, especially towards autumn and during summer.

Compare BALLING, das Akklimatisations-Erysipelas; in Heidelberg Klinischen Annalen, vol. vii. p. 176

The *Vesicular Erysipelas (Erysipelas vesiculare, bullosum)* is a variety of this kind of erysipelas, in which either at the onset, or in the course of the disease, vesicles of various size arise, sometimes like a miliary eruption, sometimes like peas or hens' eggs, which often run together, and, after bursting, form crusts, or, frequently, spreading sores.

[(1) The disease here described as true erysipelas by CHELIUS, is the *erythema* of English practitioners, and which has been well described by WILLAN (*a*) as "a nearly continuous redness of some portion of the skin, attended with disorder of the constitution, but not contagious" (p. 472;) and BATEMAN (*b*) observes, that "it differs from erysipelas inasmuch as it is a mere rash or efflorescence, and is not accompanied by any swelling, vesication, or regular fever." (p. 119.) RAYER (*c*) speaks of it as a superficial inflammation of the skin, characterized by morbid redness and heat. and the absence, for the most part, of papulæ, vesicles and pustules. (vol. i. p. 98.) Elsewhere he observes, that "it is the first stage of a number of cutaneous affections, but when permanent it constitutes a disease in itself." (p. 95.)

The vesicular erysipelas, which CHELIUS considers merely as a variety of his erysipelas, is a distinct and definite disease, the acute erysipelas of WILLAN and BATEMAN, which "most frequently occurs in the face, affecting usually one side of it only; sometimes it seizes one of the extremities, and in both cases it is ushered in by a smart feverish attack. The colour is higher than in the other species of the disease, and the burning heat and tingling in the part are exceedingly distressing. The swelling generally appears on the second night or third day of the fever; the vesications rise on the fourth and fifth, and break or subside on the fifth or sixth, when the redness changes to a yellowish hue, and the swelling and fever begin to diminish; and on the eighth day

---

(*a*) On Cutaneous Diseases. Lond., 1808. 4to. according to the arrangement of Dr. WILLAN.
(*b*) A Practical Synopsis of Cutaneous Diseases London, 1819. 8vo. 15th Edition.
(*c*) Traité Théorique et Pratique des Maladies de la Peau. Paris, 1826. 2 vols. 8vo.

both disappear; on the tenth the new cuticle is commonly left exposed, the old one having separated, and the brownish or dark scab, which had formed where the fluid of the vesications had been discharged, having fallen off." The disease runs its course more quickly in the young than in those of more advanced age; and "the vesications, in the latter instances, are often succeeded by a profuse discharge of acrimonious lymph for several days, so that scabs do not form. Suppuration very rarely occurs in this species of erysipelas, especially when it affects the face." (pp. 126, 7.)

From this description it is quite evident that CHELIUS is incorrect in making his vesicular erysipelas a variety of his true erysipelas; the latter being really erythema, and therefore an exanthematous disease, whilst the former, which is our acute erysipelas, is a bullous disease. It was necessary also to make these observations to prevent the confusion which would otherwise arise from the acceptation in which CHELIUS uses the terms erysipelas and erythema, differing so entirely from that in which they are employed by English writers.—J. F. S.]

83. The *Spurious Erysipelas* or *Pseudo-Erysipelas* is a continual inflammation of the skin with some redness, (*Erythema*,) which has nothing in common with the true erysipelas but its external appearance, and is produced by any pretty strong irritation of the skin. Influences of this kind are, scorching by the sun, slight burning, cold, irritating ointments and plasters, cantharides, mustard plaster, horse-radish, the juice of toxicodendron, hard rubbing, wounds and injuries of all kinds, stagnant humours, swellings, hardenings, and so on. Hence inflammation of the skin is produced, either directly or indirectly; in the first case appearing immediately, in the second as a consequence of some other disease, which has been excited by inflammation. The inflammation of the skin, thus produced, is either superficial, or it penetrates deeper into the substance of the skin. The former is more like erysipelas, but the latter has rather the character of phlegmonous inflammation, and the more the cellular membrane and muscles are attacked by it, so much the less does the disease deserve the name of inflammation of the skin.

84. According to its various causes, *Pseudo-Erysipelas* is divided into two kinds:—

First. The *Erythema idiopathicum*, which is merely consequence of external irritation (from cold, heat, corrosive substances, slight injuries, and so on.)

[A very frequent form of idiopathic erythema is that caused by friction, and commonly known as *Intertrigo*, which is well exemplified in the chafing of the skin in fat persons; often also noticed in the folds of the skin of the neck, groin and hams, and behind the ears of infants, and resulting from inattention to cleanliness, the moisture and sebaceous secretions which are left on the delicate skin of these parts irritating it, so that often the character of the perspiration is changed to clamminess, and its quantity increased, and, where it can dry, superficial thin scabs are formed, even before excoriation of the skin occurs, which soon takes place, and, if left alone, runs on to gangrene. Erythema may also originate from the flow of other natural secretions over the skin, as the spittle over the chin and neck, if the lower lip be imperfect, or do not retain its proper place; the urine, in incontinence or in perineal fistula; the tears over the cheek; and so also the increased and altered mucous discharge from the nostrils during catarrh, will cause severe erythema of the upper lip.—J. F. S.]

Second. The *Erythema symptomaticum, consensuale*, which is the simple reflection of another disease of the structures lying deeper beneath the skin. This other disease may be,

A. An inflammatory or serous distension of the tendinous expansions, and aponeuroses, with the intensity of which the accompanying inflammation of the skin increases, and oftentimes spreads very far, as, for instance, in œdema, in injuries of the head, in whitlow, and so on.

[This is the "erysipelatous inflammation" which, HUNTER says, "often arises from accident; but then it is commonly a secondary inflammation, although not always; for, the first shall have gone off, and, when the suppuration was to take place, it shall have come kindly on, but afterwards the erysipelatous shall take place. * * * It is more commonly a cutaneous inflammation than situated in the deeper-seated parts; although, in some constitutions, every inflammation, wherever it exists, will most probably be of this kind; however, the skin appears to be most susceptible of it, because it will spread over a prodigious surface of skin, while it does not affect even the cellular membrane underneath. * * * It is more common in the summer than in the winter, more especially in hospitals; and, I think, takes place oftener after wounds on the head than any other. I have often seen it begin round a wound on the scalp, extending itself over the whole head and face; the eyelids being very much swelled, the ears thickened, and it has advanced to the neck, shoulders and body; creeping along both arms, and terminating at the fingers' ends: that which attacks the body, often goes along the body to both thighs, down the legs, and terminates at the ends of the toes; and, while this is going on, it is as expeditiously cured behind, and the skin peels off the cured parts: however, this is not always the case; it often stops, and where it proceeds so far, it is commonly becoming milder." (pp. 270, 1.)

The form of the disease just described by HUNTER, is the *erratic erysipelas* of WILLAN and BATEMAN. It, however, more commonly occurs on the limbs and body, than on the head, and frequently accompanies punctured wounds, or poisoned wounds in dissection. In the latter cases, it is often extremely troublesome, and continues for weeks; making its appearance in the neighbourhood of the wound, after the more severe symptoms, either without or with suppuration and sloughing, have subsided, and the patient seems nearly convalescent: it will run up and down finger after finger, consecutively, and I have known the fingers thus affected twice or thrice during the same attack.

That form of the disease which sometimes follows scalp-wounds is rather the *œdematous erysipelas* of WILLAN and BATEMAN than the erratic. It is described by those writers "of a paler red, or of a yellowish-brown colour, is accompanied by less heat and local distress" than true, or even erratic erysipelas; "its surface is smooth and shining, and, if it be strongly pressed with the finger, a slight pit remains for a short time." The scalp swells enormously, and the disease spreads more or less slowly and extensively, till "the whole face is much enlarged, so that the form of the features is scarcely recognised, and the appearance is not unaptly compared by WILLAN to that of a bladder distended with water." (p. 127.) Generally, as far as I have observed, this œdematous erysipelas is not accompanied with vesication.—J. F. S.]

B. A metastatic deposit in the cellular tissue, periosteum, and glands, in gastric, rheumatic, arthritic, and puerperal diseases. In such cases, when the masses deposited are fluid, the parts attacked quickly die, and are given up to the ulcerative process. Often, within a few hours, in a previously healthy part, (mostly of the thigh or leg, especially on the right side in persons advanced in years,) a redness of the skin comes on with fluctuation and diffused pain, in which, after opening the abscess, whole sheets of dead cellular tissue may be withdrawn; and, if the periosteum be involved, the bone may be felt bare. Usually, however, its course is not so quick; the local pain is preceded by more or less severe shiverings which, from their repeated accessions, resemble an ague. The fever continuing, the skin is rosy red at the painful parts, and somewhat œdematous, so that it retains the impression of the finger. The fever becomes more active, the swelling harder, the rèdness bluish, the skin grows shining and blisters, the cellular tissue is hard and firm, the urinary and fecal discharges are changed and suppressed; with accompanying restlessness, and great agitation. At this point the disease seems to stand still; the heat, tension, and pain are unaltered; the vesicles have the same appearance. If at this time the skin and cellular tissue be cut into, a quantity of whitish fluid with a little pus escapes, a few days after, less of the thin fluid, and more pus; and, still later, a whitish lard-like substance, and upon pressure only a very little pus; the cellular tissue is dead. When it has gone thus far, the skin is destroyed, the vesicles burst, a whitish ichorous fluid is discharged, whitish or blackish spots appear which quickly spread, the cellular tissue is thrown off in large patches, the skin is entirely separated from the underlying parts, all the connecting cellular tissue between the muscles is destroyed, the skin becomes gangrenous, the suppuration is very plentiful and offensive, the destruction spreads and exhaustion follows with copious sweats, purging, and so on. If the patient's powers revive, and the disease be arrested, the formation of granulations and cicatrization is always very tedious, on account of the great destruction of the cellular tissue (1). If the masses deposited be solid, they sink into the substance of the cellular tissue, inflame and harden it, and destroy its vital relations, without causing actual death. This degeneration frequently does not occur until after several weeks, and appears with accompanying redness of the skin and with a somewhat painful, far-spread, deep-seated hardening (2). The termination of this disease (which KLUGE has commonly observed in the scrotum, and which I have seen upon the hand and fore arm) is either a tedious resolution with gradual subsidence of the redness and hardness, or death of the degenerated organ, in which the size of the part is increased, the previous hardness becomes doughy, fluctuation takes place, and the above-described destruction and *ichorousness* ensues (*a*).

[(1) This is the *inflammation of the cellular tissue*, to which I slightly adverted at p. 72; and, although very commonly confused with erysipelas, or, as by CHELIUS, with erythema, it is decidedly different from either, although both occasionally run into it. JOHN HUNTER was well acquainted with it, as will be presently seen, though he included it with erythema, under the common title erysipelatous inflammation, which he does not describe at all. He says:—"The erysipelatous inflammation is very peculiar; and most inflammations that are not of the true adhesive and suppurative kind are called so, although probably they do not in the least belong to it; and this may arise more from the want of terms, than the want of discrimination." (p. 269.) After describing erythema, which it is quite certain he means, restricting it to the skin, he proceeds:—"When it (the inflammation) goes deeper than the skin into the cellular membrane, it often suppurates; but then I suspect it is not the true erysipelatous; for, in such cases, it commonly produces mortification in the cells, by which air is let loose; this gives a strange feel, neither of fluctuation nor crepitation, and, as there are no adhesions, the matter finds an easy passage into the common cellular membrane, increasing the same kind of suppuration wherever it comes; and, as mortification is a consequence of these inflammations, putrefaction ensues, and the discharge becomes very offensive. * * * * When it produces suppuration in the cellular membrane it is often dangerous, both from the disease itself and the consequences of the matter diffusing itself much farther. * * * The sores seldom ulcerate; they should be opened early, or the matter either gets into the cellular membrane from the want of adhesions, or it separates parts that are only attached, as the periosteum from the bone, muscles from muscles, etc. Whereas the true suppurative ulcerates briskly, which therefore should not be opened early, but allowed to burst." (pp. 271, 2.)

So far as it goes, HUNTER has well described this disease; but he speaks of it as if invariably consequent on erythema, which is more rare than its following erysipelas, which he does not mention at all. It is perfectly true that, from both these diseases, the inflammatory action may descend, and attack the cellular tissue; but very commonly the inflammation begins in that tissue; and the redness of the skin is only secondary, and symptomatic of the mischief going on beneath.

Inflammation of the cellular tissue arises frequently without any apparent cause, but sometimes follows a graze or slight wound or contusion of the skin. It commences with swelling, tension and dusky redness of the limb, (almost invariably attacking the extremities,) is very painful, and has a doughy feel; it spreads very rapidly, downwards as well as upwards if it have commenced on the upper or on the middle of the lower member of the limb. The pain and tension increase, the redness becomes darker, and, if not interfered with, large patches of the skin assume a gangrenous character, sometimes accompanied with large vesications loaded with dirty serum, but very often without

---

(*a*) KLUGE; in RUST, as above, p. 525.

them. Pressure upon the skin not unfrequently gives a crackling sensation. The gangrene of the skin continues spreading, and, generally, in the course of forty-eight hours or less, the greater part, or the whole, of the skin is sloughy. If there be sufficient power, ulceration takes place at the edge of one or other slough, and a little ichorous exudation is observed, which subsequently is followed by fetid pus, and sloughs begin to separate, simultaneously with which the character and quantity of suppuration are improved and increased, till the whole of the dead parts are thrown off; but this is a result which can scarcely be expected, for the patient is generally worn out before this can take place. The constitutional symptoms in this disease are at first those of great excitement and general disturbance; the skin burning hot and dry; the pulse quick and full; the alvine secretion unhealthy and the tongue dry; the patient becomes restless, soon wanders, becomes delirious, often violently, and then drops into a typhoid state, in which condition he speedily sinks. The disease is easily distinguishable from erysipelas, by the absence of vesication at the onset, and by its darker redness; also by its usually occurring in the limbs. But, as I have already mentioned, erysipelas may subside into it, as it not unfrequently does when attacking the scalp, and occasionally also when the face is affected, specially when the regions of the orbits are concerned, in which cases I have seen some very fearful sloughing of the cellular tissue in those cavities.

The disease generally attacks adults, and more especially persons accustomed to large quantities of beer and spirits, and gross feeding. In such persons the disease often seems to occur spontaneously, and at other times from the slightest cause, as a mere scratch. But I do not agree with CHELIUS that metastasis is generally, if ever, the cause of the disease.—J. F. S.]

(2) I have once or twice seen this degeneration in the scrotum; and I think I have noticed it occasionally in the legs of people addicted to drinking, in whom it seems to have been a commixture of adhesive deposit with the serum of œdema. But, many years ago, I had under my care a woman, between twenty and thirty years of age, whose face was thus affected, consequent on repeated attacks of erysipelas previous to my seeing her. Her forehead, and face especially, were considerably swollen and fiery red, having the appearance of skin distended with œdema, and threatening to burst; but it had not any such disposition. When pressed, it was found firm and but little yielding. She did not suffer pain in any material degree, but was principally inconvenienced by both eyelids being included in the disease, and so swollen that their apertures were little more than narrow horizontal slits, so that without bowing her head much forwards she could see nothing immediately below her for a considerable distance. All sorts of constitutional and local remedies having been employed without avail, it was proposed to her that some slices (they could only so be properly called) should be taken out of the swollen eyelids. To this she readily assented, being anxious for the slighest chance of relief; and, performing an operation similar to that for entropium, I removed a .horizontal slice from between each tarsus and the corresponding edge of the orbit of both eyes, digging down to the bone, to the depth of half an inch, and cutting through cellular tissue literally converted into brawn; the gaping edges were then brought together, and, at first, she seemed a little benefited; but the wounds soon healed, and no advantage was derived. In a second operation, I removed some short vertical slices from the lower lids, but not with much immediate advantage. I have constantly seen her up to the present time, and, probably from the contraction of the scars, the apertures of the lids are increased but are still small. The face is also somewhat less, but it is still very full and deformed.—J. F. S.]

GULLIVER (*a*) mentions two peculiar affections of the cellular tissue which he has observed, and which he believes by no means uncommon among soldiers on service, who frequently "complain of inability to sustain the fatigue of marching, in consequence of swelling and pain in the feet and ankles, produced by this exercise. In many instances the cause of the affection is very obscure, and in some it may probably be ascribed to simulation; but I have seen cases in which the complaint was evidently connected with a change of structure in the subcutaneous cellular membrane of the legs, generally presenting itself in one of two forms.

"In the first and most numerous class of cases, after the patient has been long subjected to the inconvenience of swelling around the ankles and back of the feet, the disease assumes a more inveterate character,—that of thickening and induration of the subcutaneous cellular texture, so as to leave no further doubt of the incapacity of the man for active service. In one instance, in which the disease attacked the right leg, the part was

---

(*a*) Remarks on certain Affections of the Cellular Tissue of the Legs; in Edinburgh Medical and Surgical Journal, vol. xlvi. 1836.

constantly bedewed with perspiration, emitting a peculiarly offensive odour. The affection sometimes occurs in both extremities, and frequently in one only.

"In the second description of cases, although the soldier assigns the same cause of disability as in the preceding, the anatomical character of the disease offers a marked difference. There appear simply to be induration and rigidity, without thickening of the subcutaneous cellular substance. I know of no specific term by which it could be appropriately designated. The lower part of the leg, and frequently the back of the foot, appears hide-bound, the limb feeling hard and smooth, from loss of extensibility in the filamentous web, which no longer possesses that yielding looseness necessary to the due performance of its functions, so that the smallest fold of the skin cannot be grasped between the thumb and finger. The affection is unattended by swelling, except incidentally from unusual exertion. The examples which have come to my knowledge have been invariably confined to one extremity. * * * Of the first, which, in its advanced stage, may be considered as a species of compact œdema, we find no account in the accurate Treatise of Dr. CRAIGIE, and only a doubtful notice by Dr. OTTO; of the second, I am unaware of any description." (p. 309.) "The chronic induration and thickening of the cellular substance may probably arise from a variety of causes, of which repeated attacks of erysipelas appear to be one; but the first two cases described in this paper, as well as others which I have seen, were not preceded by inflammatory symptoms. Nor was there any swelling or pain in the tract of the absorbing vessels." * * * It would appear merely conjectural to refer the affection to a change in the veins; but the following circumstances are worthy of remark in connexion with the subject,—viz., the examples of phlegmasia dolens, from inflamed veins; of œdema of the lower extremities, from the accumulation of clots in the veins of the limb, without their obvious inflammation, and of chronic œdema from the irregular congestion of the capillaries, without any discoverable alteration of the venous trunks during life.

"But we have no reason to suppose that the induration without thickening of the cellular substance is dependent on any change in the veins; and, until the precise anatomical character of the disease has been shown by dissection, the descriptive appellation should be admitted with reserve. From the unaltered size of the limb, it is difficult to ascribe the hide-bound condition of the part either to hypertrophy or atrophy of the cellular substance; for which reason it appears most probable that the affection is simply an induration or rigidity of this texture,—an effect probably of very slow inflammatory action, sometimes arising from local injury, and not unfrequently without any assignable cause." (pp. 311, 12.)

This latter form is very curious, and I believe entirely undescribed, nor does it readily admit of solution. The former kind seems to me very similar to the brawny condition above mentioned.—J. F. S.]

85. *Symptomatic pseudo-erysipelas* is distinguished from the *idiopathic* or *common* inflammation of the skin produced by irritation; the inflammatory redness is not so distinctly spread; at some little spots it is more intense, here and there inclining to violet; the affected part is less hot, more doughy, sometimes also hard and knotty, and often at the very beginning of the disease, distinctly fluctuating to the touch. The patient does not complain of such burning, but of a gnawing or beating pain, not proportioned to the degree of inflammation, and situated deeply in the limb. The swelling also bears no proportion to the degree of inflammation, but is in direct relation to the pain. Painful and knotty hardening of the skin frequently precedes its inflammation. When the inflammation has taken place, it always spreads farther, usually, however, more slow than quick, creeping, as it were, towards the affected parts. The ordinary means of resolution are of little use; in most cases, the disease is chronic, and single spots are often observed, which suddenly become more sunken, more or less distinctly fluctuating, mortified or destroyed in some way or other. All the external causes which could have given rise to ordinary inflammation of the skin are deficient also at the beginning of the disease.

86. The etiology of pseudo-erysipelas is clear from what has been already said of its several kinds. In reference to the necrotic hardening of the cellular tissue, which is the most usual cause of pseudo-erysipelas, it must

be remarked that, although its origin is in many cases obscure, yet a peculiar state of atmosphere, specially the operation of severe cold and a certain change of temperature, must contribute much to it. Hence this disease occurs more frequently in winter and in the coldest months, than at any other time of the year, more frequently in weakly people and on the lower limbs, more commonly in advanced age and in the male sex.

87. The *Treatment* of simple erysipelas requires especially action on the biliary and cutaneous systems. Emetics have generally here the best effect if employed early, and cannot be replaced by purgatives. If after their operation the fever continue, cooling acid purgatives with suitable antiphlogistic diet must be employed. Not until the fever has entirely or for the most part subsided and no further indication for depletory remedies exists, can sudorifics alone be relied on. Only if the erysipelas, especially on the face, be accompanied with high inflammatory fever, the head thereby attacked, the erysipelatous parts swollen, burning, and painful, accompanied with confusion and determination of blood to the head, should blood-letting or bleeding with leeches behind the ears be employed before the use of emetics, and at the same time the blood should be withdrawn from the head by warm foot-bathing, mustard poultices upon the calves of the legs, and so on. It is always, however, to be remembered, that erysipelas, even when connected with inflammatory fever, will not bear the same active antiphlogistic treatment as other inflammations, and is specially prone to return after any exhaustion.

[Two very different plans of constitutionally treating erysipelas are employed in this country, and, curious as it may appear to be, with success. The old method, still largely practised, is that on the antiphlogistic plan, first clearing the bowels, and then employing salines and antimonials; and, when the inflammatory action has subsided, administering gentle tonics, as tincture of calumba and the like. This treatment, which formerly I have seen constantly practised, and to which I have been personally, often in my youth, subjected, was generally very successful, and is, by many practitioners, still considered the best. The second mode is directly the reverse, and was, I believe, first introduced, fifteen or twenty years since, by my friend and colleague, Dr. WILLIAMS. It consists in the entire reliance on wine (port wine usually) given often to the amount of eight and twelve ounces a day, varying according to the age and condition of the patient's constitution, but without any consideration of the stage of the disease. And this practice has certainly been very successful, and is at our hospital now almost invariably followed. I prefer, if the case come under my care early, besides administering a dose of calomel and rhubarb, (which should never, under any circumstances, be omitted,) to give some saline and antimonial for twenty-four hours; rarely beyond that time do I defer giving the wine, the effect of which in checking the progress of the erysipelas is, generally, soon very decided. Bleeding, either from the arm or by leeches from the head, is, I believe, very unadvisable. The disease almost invariably occurs in constitutions without power, and therefore bleeding favours rather than diminishes it.—J. F. S.]

88. The *Local Treatment* of true erysipelas has no other object than to defend the diseased part against external injury, which may be effected by the use of dry warmth, by bags of camomile and elder flowers, by warm flannels, and so on. All moist, especially wet or greasy remedies, are injurious, as they repel the erysipelas, or produce œdematous swelling of the part. If, after the fever and swelling have for the most part ceased, there remains an œdematous, colourless swelling, the herb bag must be smeared with camphor, or the swelling covered with green-oil cloth, and swathing of the part made use of. According to RUST, only the vesicular erysipelas and its varieties, especially if they exhibit a more chronic than acute course, require the application of moist warmth in a proper vehicle, for which purpose GOULARD's lead wash with a small addition

of laudanum is best. If the erysipelas run into ulceration or gangrene, attentión must be paid to giving free escape to the ichor; the general and local treatment must be regulated, as before mentioned, according to the character of the fever, and the rules given in reference to abscess and gangrene, and clearance of the bowels, must be especially remembered.

[The local treatment of erysipelas is very simple; warm or cold washes, as may be most agreeable to the patient's feelings, consisting of water with a little spirits of wine, are best, and I think preferable to either warm or cold lead wash, which renders the cuticle harsh and unyielding.

If there be much tension of the skin, the practice recommmended by Dobson of making a dozen or twenty punctures with the point of a lancet is very beneficial, and agreeably relieves the hide-bound sensation which the patient feels.—J. F. S.]

89. In *idiopathic erysipelas* the treatment must be guided according to the degree of the inflammation. General antiphlogistic treatment is rarely necessary in this case; usually the application of leeches and of cold water or lead wash are sufficient for resolution.

[Leeches should never, under any circumstances, be applied locally, as the irritation resulting from their use itself frequently excites erysipelas or rather erythema. If absolutely requisite, puncture with the lancet is to be employed.—J. F. S.]

90. In *erythema consensuale* the treatment varies according to its original cause. If it depend on the tension of aponeurotic expansions, incisions, warm bathing, friction with mercurial ointment, warm fomentations and poultices must be applied. If the erysipelas appears only as a reflection of deeper disease of the periosteum, of the tendons, or of cellular tissue, so long as the disease continues purely inflammatory, abstraction of blood, leeching, applications of cold lead wash and free mercurial friction, and, in metastasis especially, mercurial laxatives and warm aromatic fomentations, must be used; in gastric symptoms, with loaded tongue, heartburn and the like, a vomit should be first given, by which principally the course of the disease is rendered less severe. But, if gangrene or ulceration have occurred in the deeper parts, and there appear a spot particularly discoloured or fluctuating, it must be opened and the wound dilated with the blunt-ended bistoury upon the finger in every direction where the destruction of the cellular tissue has occurred, in order to discharge the pent-up ichor and the often large pieces of completely dead cellular tissue. The further treatment consists in supporting nature to throw off the destroyed parts, to sustain the sinking powers, and to produce good suppuration. According to Rust, there may be applied locally bark, camphor, myrrh, charcoal, camomile flowers, turpentine oil, camphorated spirit, pyroligneous acid, spirituous aromatic fomentations, and so on; internally, powerful tonic remedies are to be used in connexion with mineral acids, and, if thereby a good suppuration is produced, the healing may be aided by the application of a moderately compressing bandage. I have, however, noticed, that under this stimulating local treatment, the destruction and unhealthy suppuration as well as the general irritation have increased, and that by the use of warm fomentations and a suitable general treatment improvement has been much more quickly produced; I, therefore, only use warm applications locally. In great hardening of the skin and of the underlying cellular tissue, I have always effected a perfect resolution by mercurial infriction and malt baths.

[Neither leeches, cold washes, nor mercurial friction are, according to my experience, of any material advantage, and therefore hurtful, as causing waste of time. The best local treatment, and which I almost invariably adopt, is, when the skin is tense, shining, and deep red, to make several incisions, according to the extent of the disease, from an inch and a half to three inches in length, which I think preferable to very long cuts, just through the skin into the cellular tissue, which should be so disposed that every four should have interposed between them a sort of diamond-like space, and thus, when several cuts are made, the skin has a net-like appearance, and yields in every possible direction. The object is not to obtain blood, which, indeed, I generally endeavour to avoid by bathing for a few minutes with cold water, if there be any disposition to bleeding, but to allow the cells of the cellular tissue to empty themselves of the fluid with which they are loaded, the effect of which is, that the skin, being further relieved of tension, is less likely to slough, and the tissue itself being no longer squeezed by the effused serum, the blood passes freely through its capillary vessels, and its life is preserved, instead of it becoming strangulated. If the tension be not sufficiently relieved, or if the disease be continued up the limb, it will be necessary to make additional cuts from day to day, which is the only chance we have, that I am aware of, to prevent the death of the cellular tissue, and it each time relieves the patient's sufferings most remarkably. In one instance of a man who had inflammation of the cellular tissue of the back of the hand, resulting from a strain, and which travelled up to the chest, I made about thirty cuts, mostly three inches in length each; during the course of the week, nearly the whole cellular tissue of the arm sloughed; but he completely recovered, his arm, however, closely resembling a piece of scored pork.

In these cases brandy, wine, porter, general good feeding, and humouring the appetite, are absolutely necessary, and infinitely preferable to medicine, which should be restricted to an opiate, or an occasional dose of castor oil, as needed.—J. F. S.]

91. In the treatment of the various kinds of erysipelas, we have given the treatment proper for each, and which has been proved by experience. The opinions, however, of the most distinguished physicians differ from each other in many important points on this subject. Thus the incisions should only be made in pseudo-erysipelas, and of the suitable length and depth, according to Rust, Dupuytren and Lawrence; while, according to Hutchison (*a*), they should be made early and in considerable numbers; but Dobson (*b*) employs numerous punctures with a lancet in all kinds of erysipelas and on all parts of the body. In pseudo-erysipelas Dupuytren (*c*) professes, in some cases, to have effected a satisfactory resolution by blistering the diseased part: he, however, considers this remedy as doubtful, as in other cases he noticed deterioration and sloughs occurring after its use. But, in all cases of common erysipelas, if the tongue be moist and little red, the skin moderately hot, and slight general reaction connected with the local inflammation, he considers the suppuration produced by one or more blisters upon the inflamed part as the best mode of effecting resolution. Some (*d*) would arrest the extension by the application of a blister at the margin of the erysipelas; but others (*e*) entirely reject their use. Bretonneau (*f*) and Velpeau (*g*) have had the happiest results from moderate compression of a limb attacked with inflammation, even when the transition to suppuration seemed unavoidable and all other remedies had failed. Lawrence and Duncan have, on the contrary, observed bad effects resulting from this practice (*h*).

[Another mode of attempting to check the spread of erysipelas, is that of enclosing it, if small, within a space bounded by a belt, a quarter or half an inch wide, made on the skin with nitrate of silver; or, if a limb be affected, by gartering it in the same way

(*h*) Lawrence, as above.

with the nitrate of silver some inches above. I have sometimes seen the erysipelas extend up to the belt and there stop; at other times I have observed it move on without having met with any check. I am therefore doubtful of the efficiency of the nitrate of silver; but, if used, it should be carefully applied, even to blistering the skin, otherwise it is certainly useless.—J. F. S.]

92. As various also are the opinions as to erysipelas consequent on wounds, (*Erysipelas traumaticum,*) in which the most opposite fomentations, blisters, incisions and scarifications, cauterization with the red-hot iron, (Larrey,) antiphlogistic treatment, emetics, and so on, have been recommended. If the above-described different kinds of erysipelas and pseudo-erysipelas be borne in mind, and, if it be remembered that the traumatic erysipelas, which in four or five days accompanies wounds, is produced by different causes, as too great irritation of the wound by improper bandaging, foreign bodies, the application of greasy, too stimulating or too hot softening remedies, cold moist air, a bruised and torn condition of the wounded part, wounds of fibrous structures, gastro-biliary affections, mental excitement, improper food, and the like, it may be easily perceived, how a proper observation of the various causes can alone prevent a merely routine treatment of so important a disease (*a*).

93. *Burns* (*Combustiones, Ambustiones,* Lat.; *Verbrennungen,* Germ.; *Brûlures,* Fr.) are produced by fire or heated substances touching our bodies. The action of caustic substances, especially of the concentrated mineral acids, corresponds precisely with that of fire. According to the degree of heat, in fluids therefore according to their consistence and capacity for heat, according to the duration of the contact and the delicacy of the part touched, different degrees of burns are produced, which may be thus distinguished: 1. *as superficial inflammation* (*Erythema;*) 2. *as more*

(*a*) Compare Larrey, Clinique Chirurgicale, vol. i. p. 21; Balling as above.

severe inflammation with rising of the cuticle into blisters (Vesication ;) 3. *more deeply penetrating, higher inflammation, with the destruction of the cuticle and of the mucous net;* 4. *gangrenous destruction at different parts and to various depths.*

Degrees of burns are variously distinguished, as they are considered not merely as to their intensity, but also with reference to their spreading into deeper parts. Many point out but three degrees. DUPUYTREN has described six; of which the latter, however, only differ in proportion as the gangrenous destruction is more or less deep, or involves the whole bulk of the limb. The four above-mentioned degrees are based on the corresponding steps of inflammation, viz., the erythematous, exudative-inflammatory-vesicular, the phlegmono-suppurative and gangreno-sphacelous. According to the variety of causes producing burns are these degrees of burning frequently blended with each other; for instance, in burns with hot fluids.

94. The *first degree* of burn, arising from hot vapour, from the momentary or lengthened touch of a more or less hot body, produces a bright uncircumscribed redness of the skin, as in erysipelas, which for the moment disapppears on pressure of the finger, without swelling, and is accompanied only with increased turgescences of the skin and a little pain. Febrile action only sets in if this degree of burn be much spread and in sensitive persons. The redness of the skin either disappears after some hours or days, when the cuticle scales off.

95. In the *second degree*, which is most commonly produced by hot fluids, the cuticle rises either at once or gradually into larger or smaller blisters, filled with clear or yellowish fluid, the redness and swelling of the skin is more distinct; the pain severe, burning; and, according to the degree of these appearances and the extent of the burn, do febrile symptoms set in. These blisters either shrivel together and dry, the fluid being absorbed and the skin thrown off, or, if they burst and are opened, the fluid is discharged, the blister falls together, dries, and after some days either a new cuticle is produced or the exposed part suppurates. The healing leaves no scar.

96. The *third degree* of burn is usually produced by the flame of fire or by the lengthened touch of hot bodies, especially of hot fluids, and is characterized by gray, yellowish, or brown spots, which are thin and soft, insensible to light pressure, but are painful if the pressure be increased; at the same time generally appear blisters full of brownish or bloody fluid; the surrounding parts are very red and much swollen. The general reaction corresponds to the degree of the inflammation. After six or eight days, and frequently later, the remains of the destroyed cuticle and mucous net are thrown off, and the cure is effected by granulations and the formation of a white glossy scar.

97. In the *fourth degree* of burn the destruction penetrates either through the entire thickness of the skin and cellular tissue, or deeper into and through the muscles to the bone, or the whole part is destroyed and charred. This degree is produced by long contact with fire, red hot or molten metals, boiling fluids. The sloughs differ in thickness, are completely insensible; soft, gray, or yellow if produced by hot fluids; brown or black, dry, hard, and sounding when struck, if caused by fire or dry hot bodies. In the immediate neighbourhood of these sloughs the skin is drawn into radiating folds; the surrounding parts are extremely red and swollen, very painful, and frequently beset with blisters. The slough is thrown off by the suppuration which takes place around it, and a more or less deep suppurating space is produced, which commonly has a

much larger extent than the slough, because in consequence of the severe inflammation its immediate belt is destroyed by gangrene. The granulations most usually are developed very quickly and luxuriantly, the edges quickly draw together, and shapeless, hard, contracted, tough scars are produced, whereby the direction and motion of the part is often changed and impeded, and the latter even perfectly destroyed. After the throwing off of a part which has been entirely charred, a more or less uneven stump is produced.

98. More or less severe symptoms ensue according to the different degree and extent of the burn, according to the importance of the burnt part, and the constitution of the patient, and not merely does the degree, but also the extent of the burn, determine its danger. In the first two degrees the inflammation is easily resolved, and only if it affects a large extent of the body, and still more in the higher degrees, does febrile reaction set in, when, on account of the disturbed functions of the skin and the changed relations between the external and internal skin, the mucous membrane of the intestines is quickly affected, and uneasiness, loss of sleep red dry tongue, nausea, vomiting, high nervous excitement, delirium, and the like come on. From the severity of the pain cramps and convulsions occur, especially in sensitive persons. In extensive burns death may ensue rather suddenly from the greatness of the pain, from the quick stopping of the functions of the skin, from the excessive flow of blood to the internal parts where on dissection either no internal derangement is seen, or where a gorging of the brain and mucous membranes with blood and even effusion into their cavities is observed ; or from the severity of the fever, especially if accompanied with inflammation of internal parts, of the stomach intestines, brain, more rarely of the lungs and of the pericardium ; or from the very copious and continued suppuration, by which the powers are exhausted. The production of unsightly hard scars, or the growing together of neighbouring parts, may cause disturbance or complete stoppage of their functions.

[Burns, from whatever cause, are generally more dangerous than scalds, as they are rarely unattended with destruction of the skin and subjacent parts, whilst, on the contrary, scalds more usually produce only vesication. If, however, a person be completely immersed in boiling water, even for two or three minutes, of which I once saw a frightful instance, of a dyer who fell into his copper, he will be destroyed in ten or fifteen minutes. But I have several times, on the contrary, seen persons, whose entire surface has been charred by fire, live for many hours. This remarkable difference may, perhaps, be accounted for by presuming that the hot water, passing through the mouth and nostrils into the pharynx, causes speedy effusion into the loose cellular tissue connecting the skin with the laryngeal cartilages, and so, by narrowing and closing up the aperture of the windpipe, producing suffocation.

Both burns and scalds, however, are dangerous, more in reference to the part which they attack, than the extent of surface they injure; thus, scalds or burns on the chest and belly especially are far more dangerous than on the limbs, although the injured part be twice or thrice as extensive; and children who are burnt or scalded on the chest most commonly die in two or three days after the accident; in a few instances they may live a week, but they rarely ever recover. I recollect only a single instance of recovery, after severe burn on the trunk, in a child about six years old, in whom the whole front of the belly and flanks were burnt and a considerable part of the skin destroyed. I do not recollect to have observed convulsions in these severe cases, as mentioned by our author and other writers; but, if they be fatal in a few hours, the patient generally, almost at once, drops into a state of stupor from which he never after rouses; and examination after death shows the brain loaded with blood, or, if life be prolonged, effusion of serum is observed on the membranes, and in the cavities of the brain, and, less commonly, also in the serous bags of the chest.—J. F. S.]

99. The slighter degrees of burn require merely the application of cold water, or the dipping the part in cold water; all other of the prescribed remedies, lead wash and so on, act only by their coldness. If fever be present the internal use of antiphlogistic remedies and a suitable diet must be combined with the local treatment. If the cuticle have been raised into blisters, they should be opened with a fine lancet, without removing the skin, so that the contained fluid may escape. If they be small, they often, under the use of cold, fall together and dry. If the part be deprived of its cuticle, generally it will not bear the cold application, which irritates, and increases the pain; but simple, mild, soothing remedies, mucilaginous, mild poultices or fomentations, a liniment of pure oil and yolk of egg, fresh butter, and other mild salves may be spread on pieces of soft linen, which should be applied over the burnt part, and often changed, or they should be frequently sprinkled with the remedies, to prevent their drying and sticking, so as to soften and cool by their frequent renewal. Cold is always to be applied to the neighbourhood of the parts deprived of their cuticle. When suppuration is established, and the extreme sensibility of the affected part reduced by the use of mild remedies, astringent and drying applications are to be gradually had recourse to: linseed oil, with lime water, zinc ointment, and so on. Lead ointment is said to produce ugly ill-shapen scars, which, however, I have not observed. If much proud flesh occur, it must be kept down with nitrate of silver. If mortification be produced at the instant of the burning, cold application, or, if the parts are very sensitive on account of the destruction of the cuticle, merely softening and soothing applications must be used till the slough is thrown off by the suppuration, when the remedies aforesaid must be employed. Sloughing rarely extends in this case, if not accompanied by deterioration of the juices. In other respects its treatment, even when resulting from the inflammation depending on the burn, is to be after the same general rules laid down for gangrene.

The remedies especially recommended for burns are very various, and in part completely contrary to each other in their operation. 1. Popular remedies, such as poultices of scraped potato, apples, moist earth, and so on, which are cooling by their proper renewal. 2. Applications of spirituous fluids, æther, alcohol, brandy and so on, if used cold, act also coolingly by quick evaporation; if warm, they can only act as counter irritants: but all burns in which the *rete cutaneum* is exposed must be protected from irritation. 3. The burnt part is brought near to the fire immediately after the burning. 4. Wraps, by which the burnt parts are kept perfectly closed against external influences. The overlaying of fine cotton or wadding, to be kept moderately tight with bandages till it falls off. If blisters are present, they must be first punctured. The strewing with flour and bandaging with dry linen. If pain recur, the linen should be removed and the flouring repeated again and again till it is a quarter or half an inch thick. In very severe burns, after a fortnight, a fourth of calamine powder is added to the flour and applied moist. Covering with chalk, smearing with amber-varnish or tragacanth mucilage spread on blotting paper or fine linen. The watery solution of lunar caustic, recommended by FRICKE, operates in a similar way, by defending the sensitive surface and furnishing it with a covering beneath which speedy healing takes place. In like manner is the operation of kreosote to be explained, from which, when diluted with water, or mixed with grease as a salve, I have frequently observed the best consequences. 5. Various ointments for burns, consisting of fat, butter, wax, cream, and the like. LARREY forbids all cold and cooling remedies, and uses saffron ointment and ointment of styrax. 6. Solution of chlorate of lime, wherewith the bandage is to be frequently moistened during the day, causes a slight itching for about ten minutes, and is, according to LISFRANC, useful in slight degrees of burn, producing new skin in twenty-four hours; in higher degrees the suppuration is diminished and improved.

Much difference of opinion has existed and still exists among English surgeons, as to the choice of remedies for burns and scalds. Whilst some prefer moist applications, cold or warm, either as washes or liniments and ointments, others advocate the use of dry substances, as cotton or flour and the like. I shall first mention some of the more prevalent plans of treatment, and afterwards describe my own ordinary practice, without, however, claiming for it any great degree of originality.

James Earle was the principal supporter of cold moist applications in form of very cold water or even ice, pounded and applied on clothes or in a bladder. Hunter observes:—"Cold lessens all inflammations, and is a very good application where it can be applied; but it cannot be applied so universally as others. However, cold has this disadvantage, that the pain, although removed while under the application, occurs with double force when it is removed, much more than from any of the applications; and the reason is evident, for, as the warmth returns, the pain is increased by the warmth, even in sound parts." (p. 218.) Henry Earle (*a*), also, although he advocates both cold and warm applications on certain conditions, notices the objections which exist in reference to the use of cold, at the same time that he mentions its advantages. He says:—"The advantages of the plan (the application of cold) are, that it may generally be resorted to without delay, and that it has the effect of affording immediate relief. The disadvantages attending it are, it is necessary to continue or renew the application of cold for a considerable time, as the heat and pain will return, unless the diminished temperature be steadily maintained. On this account it is that, in certain delicate constitutions, and especially when the injury extends to the chest or trunk, this cooling plan of treatment cannot be employed without risk. (p. 301.)

The treatment recommended by Kentish (*b*), and consisting of the primary application of warm and stimulating remedies, is generally practised in the coal districts of the North of England, and therefore, if for no other reason than that it has been there found successful, is well entitled to notice. I have had a little experience of its effects, and do not think it less advantageous than most other plans of incipient treatment, which is the principal point of difference in the practice. Kentish's theory of the treatment of burns and scalds is founded on the mode of treating frost-bite, the very reverse of which he considers, with a fair show of reason, is here indicated. Nor are his views to be set down as "visionary, as amusing the fancy, but never capable of improving the judgment;" nor are they "nearly unintelligible, nor unsupported by any sort of rational evidence," as they have been asserted to be by Samuel Cooper. The question "the effects of heat above the freezing point, carried to the extent of what is termed burning," being the converse of its effects "below the freezing point, commonly called the effects of cold," it will be, on the whole, more convenient to leave the discussion of till we treat of frost-bite.

Kentish's object consists in "restoring the unity of action," as he calls it, in these "local injuries from increased action," * * * *first*, by gradually diminishing the excitement or action of the part; and, *secondly*, by increasing the action of the system to meet the increased action of the part; holding this law of the system in view, *that any part of the system having its action increased to a very high degree, must continue to be excited, though in a less degree, either by the stimulus which caused the increased action, or some other having the nearest similarity to it, until, by degrees, the extraordinary action subsides into the healthy action of the part.*" With this view, holding the part to the fire seems the best mode of relief; but, as parts of the body are injured where this cannot be done, the most stimulant applications must be had recourse to; for, in this class there is little fear of any of them being greater than that which originally caused the accident; the strongest rectified spirits made still stronger by essential oils; add to which they may be heated as much as can be suffered on the sound parts; these, and many more applications of the same class will give the speediest and most effectual relief. These are only to be continued for a certain time, otherwise they may afterwards cause the very ill they were given to cure; and should be succeeded by less stimulant applications, until the parts act by the common natural stimuli. The internal mode of relief will be to give those substances which soonest excite the system to great action, such as æther, ardent spirits, opium, wine, &c., by which means the solution of continuity of action is allowed to continue the shortest time possible, and the unity of action restored, which constitutes the cure." (pp. 112–14.)

The mode in which Kentish sets about the primary dressing of burns is as follows:—

"Take a teacup and put some of the best rectified spirit of wine, or spirit of wine with camphor, or spirit of turpentine, into it; then place it in a basin of hot water, so as to heat it to what you can bear with your finger; then, by means of a rag dipped in this, or a probe armed with a good deal of lint, wash and bathe the whole of the injured sur-

(*b*) On Burns, &c.

face, which when done two or three times over, apply plasters to the whole, formed in the following manner:—Take of the common yellow basilicon, *ung. resinæ flavæ*, according to the occasion; let it be mixed up with as much spirit of turpentine as it will take to make it of the consistence of a liniment, which, when spread upon thin oiled cloth, is to be applied to the part: the wax and oil of the basilicon will fill up the pores of the cloth so as to prevent evaporation, by which means the strong stimulant powers of the turpentine, or alcohol, or camphor, or all together, are so confined upon the surface as to excite the absorbents to the very increased action we wish; and, when this has taken place, the small quantity of oil is sufficient to preserve the cuticle in a pleasant state." (p. 132.)

KENTISH disapproves of frequent dressings; "for the very quick evaporation that takes place on exposing or uncovering the surface any time during the first four-and-twenty hours is pernicious; I therefore only dress the patient once a day even at first, unless in some instances. * * * But it will be better to allow him to remain for the first twenty-four hours without being disturbed; if the plasters are spread tolerably thick with the ointment, there will be no need of using any further means till the next dressing." The parts are to be exposed to the air as little as possible, and therefore the plasters are to be prepared before the dressing is commenced. The heated pure spirit is generally not again required; therefore, at the second dressing, the redness or seeming inflammation appearing less vivid, "proof spirit or laudanum with the coldness taken off, will be sufficient for this dressing, and the plasters immediately applied." Within the next twenty-four hours, "generally the appearance of inflammation has disappeared, and where there had been any small vesication in the first instance, there will be seen such a secretion of pus as may be noticed the second day after the application of a blister; the stimulants will now have performed their office, and, if continued on, they will produce unpleasant effects themselves, somewhat resembling the complaint they were meant to cure. * * * For which reason, as the equilibrium of action will appear nearly to be restored, it will now be necessary to apply less irritating substances; therefore, instead of basilicon made into a liniment with spirit of turpentine, it may be rendered into a proper consistence with camphorated oil; should even this be too strong and any appearance of irritation take place, the cerate with *lapis calaminaris* or GOULARD'S cerate, will answer every purpose, and abate any irritation that may have arisen from the former applications. What I have found very effectual in such cases, is an ointment made with the addition of a scruple of flowers (oxyd) of zinc to an ounce of the white ointment, *ung. ceræ*; this, continued until the part heals, is in general sufficient; but, if the skin should, after healing, remain very tender and likely to crack, a liniment formed of lime water and linseed oil would be useful. I have frequently found much advantage from camphorated oil in this stage. These means properly attended to, and keeping the tender skin covered from the too great action of the external air, I have found effectual in curing, and quickly restoring the cuticle to a healthy state, after most severe cases." (pp. 133–36.)

Raw cotton has of late years been used in America. GIBSON (*a*) says:—"The best application I have ever tried is *raw cotton*, thinly spread out or carded, and laid directly over the burn. The value of this remedy was ascertained accidentally, a few years ago, (previous to 1824,) by a lady living in Hartford County, Maryland, whose child was scalded by boiling water, nearly over its whole body. The mother was carding cotton, in an adjoining room, at the time of the accident, and, having no medical assistance within reach, undressed the child as quickly as possible, and covered the whole burned surface with masses of the cotton. The effect was wonderful; for the child soon became perfectly quiet, fell asleep, and, upon removing the cotton, a few hours afterwards, no inflammation whatever could be perceived. Dr. DALLAM (*b*), to whom we are indebted for an account of this case, has furnished others of a similar character, in which the cotton proved equally efficacious, and my own experience enables me to confirm his statement of its usefulness. It is only, however, in the superficial burn that this remedy can be relied on. (p. 51.)

Dr. ANDERSON (*c*) is a strong supporter of the use of cotton in burns; he says:—"The utility of cotton is most conspicuous in simply vesicated burns, where one or at most two renewals of it are sufficient; and it is to these cases that I believe its application has generally been restricted. But I have used it in a great variety of cases, recent and old, vesicated and sphacelated. From the state of the parts after a deep burn, the

(*b*) On the Use of Cotton in Burns; in POTTER'S Medical Lyceum, p. 22.

(*c*) On the Treatment of Burns; in Glasgow Medical Journal, vol. i. 1828. 8vo.

cotton generally requires renewal about every six or eight days, until the sloughs have long separated and the discharge has been diminished. The comfort enjoyed during such intervals should go far to recommend this practice, even if, in other respects, it had no advantage over that by a daily renewal of the dressings. But I am now quite satisfied that a persevering use of this remedy, even in the chronic state of burns, and in many other ulcerations, is in every respects preferable to the practice usually adopted. (p. 211.) Some care is necessary, both in preparing and in applying the cotton. For this purpose it should be finely carded, and disposed in narrow fleeces, so thin as to be translucent, by which means it can be closely applied in successive layers, and is thus made to fill up and protect the most irregular surfaces. The burnt parts, if vesicated, are to be washed with tepid water, and the fluid evacuated by small punctures; or, if more deeply scorched, they may be bathed with a spirituous or turpentine lotion. The cotton is then applied, layer after layer, until the whole surface is not only covered, but protected at every point, so that pressure and motion may give no uneasiness. On some parts it will adhere without a bandage, especially when there is much discharge; but, in general, a support of this kind is useful. Where the vesications have been broken, and the skin is abraded, or where there is sphacelus, more or less suppuration always ensues, and in such cases the discharge may be so great as to soak through the cotton and become offensive, particularly in summer; so that it may be necessary to remove the soiled portions. This, however, should be done as sparingly as possible, taking care to avoid uncovering or disturbing the tender surface. (pp. 213, 214.)

"There appears," Anderson further observes, "to be a twofold effect from this kind of treatment. The primary effect arises from the exclusion of the air and the slow conducting power of cotton, by which the heat of the part is retained, whilst a soft and uniformly elastic protection from pressure is afforded. The secondary effect depends entirely on the sheath or case formed by the cotton absorbing the effused serum or pus, and giving the best possible substitute for the lost cuticle. But, in order that the full benefit may be derived from this substitute, and to ensure an equable and continued support to the tender parts until the new skin is formed, it is absolutely necessary that this new or *cotton cuticle*, as it may be called, should not be removed except under particular circumstances, until the real cuticle is sufficiently formed to bear exposure. (pp. 217, 218.)

The use of flour as an application for burns was, I believe, first recommended by Dr. Ward (*a*), formerly one of the surgeons of the Manchester Infirmary, who appears to have employed it accidentally at first; for, finding a young woman who had been scalded from the elbow to the fingers' ends, screaming with pain and shivering as if in the cold stage of an intermittent whilst her mistress was rubbing in goose grease, preparatory to the application of scraped potato, he absorbed the grease with soft linen, and then with a flour-dredger, which happened to be at hand, sprinkled the scalded parts as completely and expeditiously as he could, which almost immediately and entirely relieved the pain. The same application was used by Ward in several other cases (p. 619.) His mode of proceeding he thus describes:—"The first object will be, (after having laid the patient upon a bed or sofa,) without a moment's loss of time, to take off the clothes and apply bread flour, by means of a common kitchen dredger, plentifully, and as expeditiously as possible, to the whole of the burned or scalded surface, and this being properly and sufficiently done, carefully applying clean dry linen cloths immediately over the flour, and such bed-clothes or other coverings as may be required to keep the patient comfortably warm, but not too hot." He strongly advises "avoiding the application of liquids of whatever kind, including oil, and liniments, ointment, and salves containing oil, all of which are extremely pernicious." If the pain be removed by this first application, it is advisable that the patient should go to sleep, even though he have no nourishment. "If pain return we must commence by removing the linen coverings or bandages from those parts where the pain is the most considerable, without attempting to remove any of the flour previously applied, except such portions as do not adhere, and then proceed as before to apply flour equally and copiously to the painful parts, by means of the dredge, which is the easiest and best method of effecting it. * * * It would also be a good general rule, particularly at the first and several of the succeeding dredgings or sprinklings, to continue the process for a certain time (longer or shorter, according to the extent of the violence, and the degree of pain complained of) after the parts become easy, (with a view to keep them in that state as long as possible,) and steadily to persevere in it either until the last-mentioned object be attained, or the parts affected shall have received a coating or covering of this invaluable article of from a quarter to nearly half an inch in thickness, and then apply

---

(*a*) A New Method of Treating Scalds and Burns. Two Papers; in Lancet, vol. ii. 1828.

the bandages, as before: and, secondly, not to disturb those places which still continue easy in consequence of having undergone one or more sprinklings or dustings, until the return of pain or uneasiness shall indicate the necessity of repeating it. And, in this manner we must proceed the first two or three weeks, or until that period shall arrive when it will be necessary to make some addition to the flour." (p. 176.) This addition consists of one portion of calamine powder to three of flour, gradually increasing the calamine till the proportions are equal, and then by degrees diminishing the flour till the calamine alone is applied, except some calamine ointment with an increased quantity of the earth, spread very thinly on linen, and laid over the powder. A moderate diet is allowed, commencing first with milk, puddings, broth, and soup. Medicines are to be used sparingly; but, if sleep cannot be obtained, then opiates,—Dover's powder, perhaps, in preference to laudanum, in proper doses every four or six hours, rather than one large dose; or an opiate friction on any uninjured but sufficiently extensive part to be effectual. Ward's explanation of the *modus operandi* of flour is, "that, by its instantaneous operation as an absorbent powder, in allaying the irritation, and partly by its coldness diminishing the temperature of the inflamed parts, it immediately arrests the rapid progress of the inflammation, and forms a fit medium or covering to prevent the access of the atmospheric air to a part of the body which is at all times peculiarly susceptible of its action (especially upon a large and extended surface of it) but which is now rendered a thousand times more susceptible than before.

Marshall (*a*) makes the following observations on the *modus curandi* of the remedy:—"This mild substance," says he, "is doubtless pre-eminent to all others hitherto in use, by imparting immediate ease to the inflamed and irritable surface; it rapidly heals by the scabbing process, in uniting with the discharge from the abraded cutis; and almost instantaneously forms a temporary semi-transparent covering, thereby assisting the natural functions in restoring the epidermis. The advantage becomes evident by stopping a profuse discharge, and the tedious progress of ulceration. That remarkable substance the animal (vegetable?) gluten, peculiarly contained in wheat, seems, in this instance, to assist the rapid regeneration of the scarf-skin, and thus protects the *cutis* and *rete mucosum*. The surface of the body being wonderfully supplied by the extension of the cutaneous nerves, in the form of a soft pulpy membrane, somewhat resembling the expansion of the optic nerve on the retina, readily affords, it is presumed, an explanation of the great violence offered to the system in all cases of extensive burn or scald. The topical remedy is equally suitable to either of these accidents, and perhaps, eventually, will be found useful in many other cutaneous affections. * * * When the flour has formed the artificial covering, the further application becomes comparatively superfluous, which is perceived by its rolling off." (p. 298.) Beyond a single slight case, which did very well, I have no personal knowledge of the effects of flour; but I know some of my friends think it a good application.—J. F. S.

On the primary treatment of these accidents Hunter says:—"Whatever will abate inflammation arising from accident, will have the same effect upon a scald or burn; and, from the diversities of applications, we have opportunities of knowing the best. Oil was long an application, but which has no virtue; spirits have also been long applied, and with very good effect. The common application, which is a soap made with lime water and oil, seemed to answer better; and now vinegar (*b*) is strongly recommended, and I think with justice as far as I have seen." (p. 218.) The best secondary treatment Hunter considers to be that by scabbing, of which he says, "the mode of assisting the cure of wounds by permitting a scab to form, is likewise applicable, in some cases, to that species of accident where the parts have not only been lacerated, but deprived of life." And then observes:—"This practice is the very best for burns or scalds, after the inflammation has either been considerably prevented, or subdued, by proper applications or by time, for which there probably are more remedies than for an inflammation arising from any other cause, as if there was something specific in such causes." (p. 217.)

The two French surgeons, Bretonneau of Tours and Velpeau, who have been already cursorily noticed as employing pressure in pseudo-erysipelas, have also recommended it in the treatment of burns. Bretonneau (*c*) advises the application of circular bandages, either dry or moistened with a discutient or narcotic wash, the vesicles, if any, having been emptied by one or more punctures. He considers that the pressure, besides preventing exhalation of the serosity, keeps the cuticle on the *rete mucosum*, and thus

(*c*) Already quoted, *par.* 91, p. 108.

protects it from the air and external agents. But, if the burnt part be stripped of its skin, oiled silk carefully fitted is to be first applied. VELPEAU (*a*) recommends strongly the employment of compression in burns, by the application of diachylon plaster spread on strips of cloth, although he very candidly admits that further experience is yet requisite to perfect this mode of cure. He lays great stress on the composition of the plaster; that it should contain neither too large a proportion of grease nor of diachylon, but that there should be a pretty large quantity of litharge, and that it should be of a softish consistence, as the effect is produced not merely by the compression, but varies according to the composition of the plaster." (p. 187.) Adopting the four degrees of burns mentioned by our author, VELPEAU says that—

"1. In those of the first degree characterised, by erythema or even tumefaction, with itching or slight pain, all modes of treatment succeed, and that it is not, therefore, in this case he hopes particularly to recommend his own. 2. That, in those of the second degree, characterised by the coming off of the epidermis or phlyctænæ, without alteration of the mucous body, the effect of the straps shows better. 3. That, in those of the third degree, that is to say, those where the mucous net-work has been partially destroyed, and in those of the fourth degree, where the skin is completely converted into eschar, his mode of treatment is almost indispensable." And he then proceeds:—"In burns of the first degree very good results are obtained from cold water, camphorated brandy, solutions of chlorures, and compression especially, but that the efficacy of the latter varies according to its application. Thus, I am persuaded that the straps are preferable to simple compression, because their employment is easier; because they do not fall off, and may remain a much longer time; that in those of the second degree, cold water, refrigerants, chlorurated solutions, especially, may cure, the phlyctænæ being first removed; for I hold much with this little operation, without which I never employ any application." (p. 186.)

His mode of proceeding is thus described:—"1. Strips of cloth spread with diachylon are to be applied upon the injured surface. 2. Indispensable that they should be applied very equally on every part of the wound to prevent strangulation. 3. They must be so applied as not to loosen, and it is therefore necessary they should make at least one turn and a half round the leg. 4. When the regions upon which they are applied are irregular, the hollows must be filled with charpie or cotton; thus, for instance, if there be a wound on the foot, the sole is to be thus padded, so as to form a rouleau. 5. The strips require different directions according to the form of the limb on which they are applied; thus, on the leg, which forms a cone, they must be placed spirally, commencing from below upwards. 6. Each strap should cover two-thirds of the width of that below it, to render the compression uniform." (p. 187.) The advantages derived from this plan of treatment are, according to VELPEAU's views, the following:—

"1. In burns of the first and second degree, the application is followed by a more prompt cure, *i. e.*, it is completed after one or two applications at most, or in a day or two. 2. That in those of the third degree three or four applications are needed, which require eight days at most, whilst other modes require fifteen days or a month. 3. That the cure of burns of the fourth degree depend on the depth of the wounds." (p. 186.)

In now proceeding to give an account of my own mode of treatment, I would premise that HENRY EARLE's observations on the careless mode in which clothing is too commonly removed after burns and scalds, are well worthy attention. "It unfortunately happens, too frequently," says he, "under these circumstances, that the first thing done is to remove the stocking, which often brings away with it large portions of the cuticle, leaving the inflamed cutis denuded; for, although in these cases sufficient time may not have elapsed for the occurrence of inflammation and the production of vesications, yet the application of the hot liquid will cause sufficient separation between the dermis and epidermis to cause it to come away on pulling off the stocking. If, instead of this forcible removal of the clothes, such limbs were to be immediately immersed in the coldest water, this most serious result would generally be prevented. The same clothes which were the medium for retaining the heat may be made the readiest means of abstracting it and of diminishing the inflammation; and, should it become necessary, in consequence of the formation of vesicles, to remove them, they should be cut away with the utmost caution, and the vesicles preserved unbroken; by which the serious consequences which follow the exposure of the highly inflamed cutis, will be prevented." (p. 301.)

The justness of these observations, as regards not merely the increase of the patient's sufferings, but also as to rendering his situation much more dangerous, especially if the vesications be large, must be sufficiently obvious. It is, therefore, scarcely necessary to

---

(*a*) His Clinique—Brûlures, Traitement par les Bandelettes de Diachylon; in Lancette Française, vol. ix. 1835.

observe that the removal of the clothes should be effected with great carefulness, and **Earle's** advice as to thoroughly soaking them in water, either warm or cold, according as the practitioner may prefer applying his remedies in one or other state, is very excellent and highly deserving of being acted on. After soaking, it is better to cut the clothes through with scissors, till the whole will drop off or the patient can be lifted out of them, rather than to drag him about as is frequently done for the purpose of saving the clothes at the expense of the patient's skin.

My own observation and experience lead me to consider the local treatment of scalds and burns as very simple, the great object in view, if there be vesication, to whatever extent, without death of the skin or subjacent parts, being to defend the exposed highly sensible surface of the true skin from the air, by affording it an artificial sheathing, and thus relieving the irritation of the nervous system. If the vesications be unbroken, I think it best to leave them undisturbed, as adhesive matter is speedily effused over the surface of the true skin, directly after the effusion of serum has ceased; an observation which may be daily made in watching the progress of an artificial blister. After a time, about forty-eight hours, the serum within the vesication becomes irritant, and this circumstance is indicated by the margin of the uninjured skin bounding it presenting a red line. The skin must then be punctured in several parts, varying according to the size of the blister, and near its base, so that the serum may escape, which it generally does slowly, the serum now holding in solution a large quantity of albumen, and not unfrequently seeming as it were contained in large cells, resembling those containing the vitreous humour of the eye, although much larger. If when the patient be first seen the blisters are found already burst, the cuticle should not, on any account be removed; for, wherever it covers it forms too good a sheathing to be taken away. In either of these cases I generally first apply linen soaked in warm lime water and linseed oil, keeping it continually wetted with a sponge, without removal for forty-eight hours, after which, suppuration having by that time usually commenced on those parts of the wound which require it for their cure, I have the lime water and oiled cloths gently removed, and all the injured parts, whether to little or great extent, enveloped in bread and milk poultices, which are renewed twice or thrice a day, according to the discharge. This application is very bland, a delicate film from the coagulable part of the milk, and the mucilaginous portion of the bread soon covers the exposed tender surface, or keeps the remaining cuticle supple and moist, thereby rendering the patient extremely comfortable, at the same time, also, that he is kept very clean, and free from offensive smell, which are points of extreme importance in the treatment of scalds and burns, as regards both the health and comfort of the patient. I rarely find it necessary to employ any other treatment; for, if the accident be not extensive, in a few days it heals, and, if it be more spread, though the time of cure is necessarily longer, yet, the same result ensues. Sometimes, however, more to relieve the patient from the strict rest which the poultice requires than for any other cause, after five or six days, the poultice is left off, and zinc ointment spread on lint or soft linen is applied.

If the true skin, or together with it more or less of the subjacent parts be destroyed, I still consider a poultice the best, most cleanly, and most comfortable application, made either simply of bread and milk, or bread and linseed meal, which are to be continued till all the sloughs have separated and granulations have been fully produced. After which wax and oil, or zinc ointment, or calamine ointment, spread on lint, may be gently bound on with a roller.

If the granulating surface be very extensive, it is generally long in cicatrizing; the granulations become pale and flaccid, or even disappear, and the pus thins and becomes limpid on the slightest disturbance of the digestive organs, thus putting a temporary stop to the cure; but, the irritation removed, things revert to their former channel, and healing is resumed. These alternations occur frequently in the course of a long cure, and must always be carefully watched and tended, as often the suspension of suppuration for a few hours causes determination to other parts, as the brain, lungs, and mucous membrane of the bowels, and the patient is cut off at the very time when there is every reason for his recovery.

From the observation I have made of the various modes of treating scalds and burns, it appears to me that it is matter of little consequence what the primary application is, provided it be warm or capable of preserving the warmth of the part. Cold washes I do not approve of, especially if the injured surface be large, as then a considerable portion of the body or limbs is suddenly cooled, and very frequently severe shivering is excited which adds much to the patient's discomfort; or if, as is often the case, the patient be already shivering, that condition is increased by the application of cold.

If stimulants be at first applied according to **Kentish's** plan, or, if cold washes be used immediately after the accident, the important point is to determine how long they shall be continued. This, in reference to stimulants, has, as already mentioned, been determined by KENTISH; and, with regard to the cold, is generally continued either till suppuration or sloughing is decidedly set up, and then, as the case may be, simple dressings, either with ointments, or absorbing powders, or poulticing, are resorted to. But I think my plan of poulticing throughout is preferable.

With regard to the vesications in burns and scalds, unless they be very extensive and attended with destruction of the underlying parts, it will have been observed from what I have already stated that I do not consider them of very material consequence if properly attended to. But many persons think it important to prevent them, and endeavour so to do by their treatment, whatever it may be. HIGGINBOTHAM (*a*) of Nottingham speaks in favour of using nitrate of silver for this purpose, and says:—"I have found that by slightly passing the nitrate of silver once over a burnt surface, the pain is increased for a short time, but then totally subsides, vesication appearing to be prevented; the black cuticle peals off in a few days, leaving the part well." And further:—"In cases in which the cuticle has been removed, the nitrate of silver applied on the surface induces an adherent eschar, and prevents the consequent ulceration." (p. 149).

The complete charring of the skin of a limb is no proof that the subjacent parts are destroyed or that they will slough and the case terminate, if there be sufficient strength of constitution by spontaneous amputation. The removal of the limb under such circumstances, immediately, is not advisable. But if it be fully ascertained that the entire mass has perished, immediate amputation is inadmissible; for the limb is under precisely the same conditions as if under gangrene from any other cause, or gangrenous spontaneously. There is always inflammation in the neighbourhood, either resulting at once from the extended influence of the destructive agent, or very shortly after set up to bring about the separation of the dead from the living part; and if, whilst either of these exist, amputation be performed, there is every probability of a sloughy stump and increase of danger to the patient. It is, therefore, necessary to wait till a line of demarcation between the living and dead parts be formed, simultaneously with which, if the progress of the case be favourable, the inflammation begins to subside, and ceases as suppuration is established, and then is the time to perform amputation if needful. Cases of this kind are not frequent (*b*).

Sometimes it happens that the destruction of skin on a limb has been so great that large wounds remain for weeks or months without any disposition to heal, and with great draught on the patient's powers, from the large suppuration which is kept up. If the use of absorbent powders, as calamine or chalk or the application of nitrate of silver in lotion upon soft rag or lint be insufficient to check the discharge, and to induce the formation of skin, then, if the patient's constitution begin to droop, and not till then, I think, should amputation be performed.—J. F. S.]

100. In burns with gunpowder, which, from the black crust covering the part, often seem much more dangerous than they really are, the grains of powder often penetrate the skin, and, if they remain after the cure, grow in and produce a bluish-black discoloration. In parts commonly uncovered, as the face, they must either at first or during the suppuration be removed with a lancet or with a needle; in other respects, the burn is to be treated according to the ordinary rules. If the grains of powder heal in, each must be removed by a little cut.

101. The employment of internal remedies in burns must be guided by the constitution of the patient and by the severity of the symptoms. If the inflammation be high, powerful antiphlogistic remedies must be employed; thereby only can the spread of the inflammation and gangrene be prevented. The great pain and nervous symptoms so commonly accompanying severe burns require at the same time opium both internally and externally in connexion with the ointments mentioned, cherry-laurel water, extract of hyoscyamus. If there be a bad state of the juices, or great weakness, these must be specially attended to in the treatment.

(*a*) An Essay on the Use of Nitrate of Silver in the Cure of Inflammation, Wounds and Ulcers. London, 1829. 8vo. 2nd Edition.

(*b*) Two cases of mortification resulting from burn, in which amputation was performed, are mentioned in the Lancet for 1840, 41, vol. ii. p. 687.

[The internal treatment of scalds and burns is too often overlooked, or little thought of, till it be too late, though it is a very important item in the restorative proceeding. If, soon after the accident, as commonly happens, the patient be attacked with shivering, which is severe in proportion to the extent of the part injured, some stimulant must be given internally, and I think a little hot brandy and water, even to children, is preferable to physic. It must be of course given with discretion: for a young child a teaspoonful of brandy mixed with seven or eight of hot water, and then a teaspoonful or two of the mixture given every quarter of an hour till the shivering subsides; for an adult half a glass or a glass of brandy to two of hot water may be given immediately, and repeated twice or thrice at intervals of a quarter of an hour, as may be needed. The patient should be quickly put to bed, covered with blankets, and warm bottles or hot bricks wrapped in flannel applied to the feet, for the purpose of re-exciting warmth.

It is matter of dispute among surgeons, as to the propriety of admistering opiates or other sedatives, an objection being made that the action of the opium interferes with the symptoms, so that it is impossible to determine whether the brain be affected by the irritation of the injury or by the action of the opium. I do not think this is matter of much consequence; but I am quite certain that soothing the patient's sufferings and dulling his nervous irritability, are most important indications in the constitutional treatment. Therefore I invariably prescribe laudanum for an adult or syrup of poppies for a child, if there be any disposition to restlessness; and, if it continue, the opiate is repeated a few hours after. The advantage derived from sleep, even for a short period, is very great, and cannot be too strongly recommended, as during that time the stinging of the burn diminishes, and the patient suffers less. If sleep at night be deficient or much disturbed, I think it better to give laudanum in sufficient quantity to procure it; in less quantity it irritates, and is hurtful, and this may be continued for some time, as may be found necessary.

In severe burns and scalds sickness and vomiting very frequently occur after the accident, and require to be checked by brandy and laudanum; but when they continue it is to be considered a very unfavourable symptom.

Till suppuration is set up, which usually is established in forty or fifty hours, the patient suffers more or less from febrile excitement; cooling drinks and saline medicine in a state of effervescence may then be given, and light farinaceous food if the patient be disposed to take it, which, however, is generally not the case. But immediately suppuration, or the separation of sloughs commences, the constitution must be supported proportionally to their degree; easily digestible animal food is then to be taken, and beer, porter, wine, or brandy, in proportion to the patient's age, habits, the degree of suppuration and extent of the slough must be used. Care, however, must be taken that the patient be not overloaded with support, which is indicated by quickened pulse, heat of skin, restlessness, and flushing of the countenance. When such occurs, this treatment must be suspended, and it not unfrequently happens that under this excitement the suppuration is suspended, and effusion of water on the brain, indicated by drowsiness and stupor or irritation of the mucous membrane of the bowels, and watery purging set in, which are very dangerous, and frequently destroy the patient. If sufficient support be not given, typhoid symptoms come on, and the patient rapidly sinks from that cause.—J. F. S.]

102. In all burns in which there is suppuration, care must be taken, especially during cicatrization, that no unsightly scar be produced; the parts must be kept in their natural place, and the contact of neighbouring parts, as the fingers and toes, be prevented by layers of linen or charpie smeared with salve.

[A most important circumstance in reference to burns and scalds is the character of the scar, in those cases where the skin has been extensively destroyed, in consequence of not merely the uncontrollable disposition of the granulations to contract during the progress of cicatrization, but also of the contractile habit of the scar itself, long after the wound has healed, when it is presumed that no further attention to the case is requisite. And even though every precaution has been taken to guard against the effects of this contractility, yet very often do the most deplorable results ensue, not only as regards personal appearance, but also in relation to diminution and restriction of the motion of the limbs. "These contractions are," as Henry Earle (a) observes, "a source of blame to surgeons;" but I cannot agree with him that even "in some instances, perhaps, such reproaches are merited, as much may be done to prevent them by proper and strict attention to position during the progress of the healing process;" and, indeed, his own subsequent observation is a complete and satisfactory refutation of this statement; for, he continues, "frequently, however, such contractions do not depend on any inattention on the part of the surgeon, but are the result of a natural process which follows cicatrization, and which has often baffled all the efforts of art to control. This process consists in an absorption of the granulations on which the new skin has been formed." (p. 97.) The surgeon, therefore, is not blameable for the results of this natural process, which not merely follows cicatrization, but actually proceeds with it *pari passu*, or even commences before the formation of new skin; for the granulations, as HUNTER observes, "being endowed with such properties, they soon begin to contract, which is a sign that cicatrization is to follow. The contraction takes place in every point, but principally from edge to edge, which brings the circumference of the sore towards the centre; so that the sore becomes smaller and smaller, although there is little or no new skin formed. (p. 483.) Besides the contractile power of these granulations," he continues, "there is also a similar power in the surrounding edge of the cicatrizing skin, which assists the contraction of the granulations, and is generally more considerable than that of the granulations themselves, drawing the mouth of the wound together like a purse. * * * This contractile power of the skin is confined, principally, to the very edge, where it is cicatrizing, and, I believe, is in those very granulations which have already cicatrized; for the natural, or original, skin surrounding this edge does not contract, or at least not nearly so much, as appears by its being thrown into folds and plaits, while the new skin is smooth and shining. (p. 484.) Whether this contraction of the granulations be owing to an approximation of all the parts by their muscular contraction, like that of a worm, while they lose in substance as they contract, or, if they lose without any muscular contraction, by the particles being absorbed, so as to form interstices, (which I have called interstitial absorption,) and the sides afterwards fall together, is not exactly determined, and perhaps both take place. * * * After the whole is skinned, we find that the substance, which is the remains of the granulations on which the new skin is formed, still continues to contract, till hardly anything more is left than what the new skin stands upon. This is a very small part, in comparison with the first formed granulations, and it in time loses most of its apparent vessels, becomes white and ligamentous." (p. 485.)

(a) On Contractions after Burns or extensive Ulcerations; in Med. Chir. Trans., vol. v.

From this constant tendency of scars to contract, even from the very beginning of their production, they almost invariably, when the wound extends over the bending surface of a joint, as, for instance, the front of the elbow, wrist, or ankle, produce gradual and permanent flexion to a greater or less degree, and, by the unconscious efforts of the patient to overcome this restriction, and the unyieldingness of the scar itself, the scar is lifted up from the surface on which it was originally formed, the elasticity of the surrounding skin being (if the expression may be permitted) presumed upon, so that it yields to the forward movement of the scar till, becoming tense, it can yield no further, whilst the scar assumes a thick web-like character, doubling on itself as it rises, and stretching from the upper to the lower member of the limb, its edge being rounded and usually thicker than the rest of its extent, so that it has an appearance very similar to the skinny expansion between the upper and fore arm of birds upon which the covert feathers are arranged.

If the burn or scald have been on the chest it is not uncommon to find the skin on the front of the arm-pits dragged inwards by the transverse contraction of the scar, and the arms pinned to the sides. The skin of the neck, also, is drawn down, so as to cause more or less deformity, and instances are not wanting where, if the burn or scald have extended on the front of the neck, the skin of the face has been pulled down, the lower lip more or less completely everted, and the lower jaw constantly depressed, except when the head is bowed forwards, which it is even sometimes permanently. Indeed, I can fully admit the truth of H. EARLE's statement:—"I have known this gradual contraction draw down the chin upon the sternum, and approximate the shoulders so much as to cause a partial absorption of the clavicles, and completely alter the dimensions of the thorax." (p. 98.)

From what has been stated it is clear that, after destruction of the skin by severe burns and scalds, the contraction of the scar, as a natural consequence, may be expected, however careful the surgeon may have been in his endeavour to prevent it, and therefore he is not blameable.

But it becomes a question, whether any thing can be done to set free the limb restricted in its motions, and sometimes rendered useless by the contracting scar. Formerly the scar web has been cut through to the bend of the joint, which at the time permitted increased extension of the bent limb; but, as the wound healed, the contraction was reproduced. I believe the whole of the webbed portion of the scar has also been removed, leaving, however, the small part which lay flat on the limb, but, when cicatrization had taken place, the contraction again appeared. HENRY EARLE, therefore, "proposed to remove the whole cicatrix, and to endeavour to approximate the integuments from the two sides of the arm, which was to be kept extended on a splint, not only during the healing of the wound, but for a considerable time after the cicatrix had formed, until, indeed, those changes which I have above described had been fully accomplished. By such practice I conceived that the contraction, which I knew must follow so extensive a wound, would take place in a lateral direction, and not in the long axis of the limb." (p. 100.) On this principle **Earle** operated on a boy of six years old, whose fore arm was contracted to a right angle by the contracting web-like scar of a burn which he had suffered twelve months before. He did not remove the scar entirely, but left it connected with the skin above, hoping it would adhere to the bared parts as far as it would cover, and so lessen the extent of skin required; but, in four days, it was found to have sloughed, not being sufficiently vascular to preserve its vitality. Directly after the scar had been detached at the operation, attempts were made to extend the arm; but "considerable resistance was met with from the forcible contraction of the flexor muscles, which had been so long accustomed to a more limited sphere of action, that they with difficulty admitted of any extension. By degrees, however, they yielded considerably, and the arm was brought nearly to a right line. When the arm was so extended, the extreme point of the cicatrix, which still remained attached to the upper arm, was deficient nearly three inches of reaching the part from whence it had been removed." The operation was performed on the 12th November, 1813, and on 20th December following the wound was healed. The splint was continued for six weeks longer; after which, the arm continuing straight, it was worn only at night for three months, and motion permitted, and, at the time of reporting the case, five months after the healing of the wound, **Earle** says:—"His arm continues perfectly straight, and he enjoys the free and perfect use of it as much as of the other." (p. 102.)

I have recently performed this operation with modification in a very severe contraction. Up to the present time (March, 1845) it has succeeded equal to my most sanguine expectations; but months must elapse before the actual result can be obtained. The description of my proceeding will appear in the following account of the

Case.—E. F., aged 21 years, a healthy country girl, had her clothes set on fire twelve years ago, in consequence of which her shoulders, chest, and arms were very severely burnt, and she was confined to her bed for nineteen weeks; but the wound did not fully heal for some time afterwards. At first there was no contraction; but, soon after, the scar began to contract, the skin over the front of the chest being first drawn towards the right shoulder, so as to form a fold across and below the front of the arm-pit; a similar process followed on the left side, and both sides of the back also soon took on the same disposition. An incision was made through the fold on the right arm-pit soon after the contraction had taken place, but without benefit, and she has since remained in her present condition.

A large scar now occupies the whole front of the chest, involving the breasts, which are not developed, and of which the very small nipples are scarcely perceptible among the coarse meshes which the intersecting transverse rays of the scar form, as they continue on either side, across and below the arm-pits to the middle of the upper arm, deepening the axillary fold by a thick skinny web, about an inch below the edge of each pectoral muscle, with a rounded thickened margin on which the cuticle is scaly, and the cutis cracky. The contracting scar draws the skin tightly on the upper and outer part of the limbs, in consequence of which the upper arms are almost closely tied to the sides of the chest. A large triangular web extends from the axillary web nearly to the radial side of the wrist of each fore arm, with a thick rounded edge confining the right arm at less than a right angle, and the left at about a right angle with the upper arm, beyond which neither can be extended.

Dec. 7, 1844. The following operation was performed on the right arm, which I had purposed performing according to **Earle**'s method, but with complete removal of the scar, and with making a second long incision through the sound skin at a distance from the scar wound, so as to diminish the dragging of the skin in bringing and pinning the edges of the scar wound together, on the same principle, that of relieving tension, with which **Dieffenbach** makes incisions in his plastic operations. It will be seen, however, that I proceeded very differently, and much further.

By an incision through the sound skin on each side of the scar web, commencing through the scar on the front of the arm-pit, and terminating below the point of the scar on the front of the wrist, I removed the whole of the scar skin which bound the fore to the upper arm, producing a long gaping wound, the skin edges of which could scarcely be approximated. I then made a second cut from the outer edge of the wound, at the front of the elbow, carrying it downwards and outwards nearly to the outside of the wrist, so that it had a lance-like shape, pointed above and wide below, and, by partially dividing its cellular connexions with the fascia of the fore arm, freed it so as, without difficulty, to bring its inner edge in contact with the corresponding edge of the scar wound. I hoped, also, by detaching the slip that the skin on the outside of the arm, which I also separated from its subjacent connexions, might be shifted upwards, might participate in forming the principal cicatrix on the upper arm, and by its wavy direction from the arm-pit to the outside of the wrist, might, when hereafter its contraction shall commence, render the drawing up of the fore to the upper arm less probable, as the scar, not being straight but wavy, would be of greater length, and, being unequally acted on, would ultimately become straight, though without shortening, so as to restrict the straightening of the fore arm.

Having proceeded thus far, I presumed I had done with the knife, and then attempted to extend the fore arm; but, having used as much violence as I thought advisable, although it was not much, I found not the least yielding, but the fascia around the front of the elbow-joint being rendered very tense and raised, I thought this might be the obstacle, and therefore, having divided it carefully upon a director thrust beneath it, I repeated the attempt at extension, with no better success.

By the division of the fascia the muscles passing over the front of the elbow-joint were exposed, and when the hand was pulled on the *m. supinator radii longus* becoming extremely tense, and seeming to be the principal resistant, I passed a director between its belly and that of the *m. flexor carpi radialis longior*, and cut the former across. Nothing was gained by this, and I then, with the concurrence of my friend and colleague Green, passed a director under the tendon of the *m. biceps flexor cubiti*, and divided it as it crossed the front of the joint. Attempts, though not violent, at extension were then repeated; but, being unsuccessful to any material extent greater than a right angle, we determined to rely on passive extension, but not to be commenced at once.

In the course of the operation the internal and external cutaneous nerves were divided as they crossed the front of the elbow and each gave a smart shock to the patient. I may observe also that I very nearly divided the brachial artery by accident, as, after the division of the tendon of the biceps, it started up, and the slight yielding which the fore arm had allowed, putting it on the stretch, had stopped its pulsation, so that it escaped me, although I had sought for it and for the median nerve, for the purpose of avoiding them, and I mistook it for a band of fascia and cellular tissue till, the pull on the fore arm being discontinued, its pulsation returned and discovered its character.

The edges of the inner wound were now brought together and connected with seven twisted sutures, beginning from the wrist and pinning upwards; but there was considerable stress on the skin, so that I feared the pins would ulcerate through, and that adhesion would not take place, as the interspaces would not completely meet; but they together with the outer wound on the fore arm were supported with some adhesive circular straps.

The patient was then sent to bed, a wet cloth applied over the whole arm; and a circular bandage carried round her chest having been fastened to the head of the bedstead, to prevent her trunk slipping down, a bandage was wound round the wrist, and, its ends being carried down over the foot-board of the bed, a four-pound weight was attached, which pulled the hand so as to promote extension of the fore arm, by tiring the flexing muscles, without giving the patient much pain. ℞ *tinct. opii* ℨss. *ex mist. camph. stat.*

Dec. 8. She had passed a tolerable night, and when seen this morning was free from pain, the weight not pulling heavily, and she is without fever. Towards night she was very restless, and the arm becoming very painful and uneasy from the pull upon it, the weight was removed. ℞ *morph. mur.* gr.ss. *stat.*, which was given at 2 A.M.

Dec. 9. After taking the sedative she had a good night, but is feverish this morning; her pulse quick and skin hot. The weight was reapplied, and the uneasiness seeming to have depended principally on the slipping to the arm-pit of the bandage confining the trunk, it was readjusted.

Dec. 10. She could not go to sleep till the weight was removed, but afterwards passed a good night without taking any sedative, and is tolerably well. The dressings and pins were removed, each strap of plaster being replaced by another before a second was removed. No union at any part of the edges of the wounds, which are angry; most of the pins had nearly ulcerated through, and the remaining bits of skin by which they held are sloughy. The weight was reapplied, but is to be removed as often as the pulling becomes painful. There does not appear any material increase of extension. She is to have a couple of eggs daily.

Dec. 13. Has continued going on well; but, last evening, being restless, she took *morph. mur.* as before, and had a tolerable night. Her bowels have been relieved this morning with castor oil; she is altogether comfortable and has a good appetite. The arm was dressed to-day with adhesive plaster; the sloughy edges are cleaning and the discharge is healthy, but the skin about the elbow is very loose. The fore arm is certainly more extended, though not considerably. Is to be dressed daily, and the extension kept up with the weight as she can bear it. To have a mutton chop to-morrow.

Dec. 20. Has been improving since the last report; the wounds are granulating kindly and the edges of the skin becoming adherent. The fore arm has been gradually coming down, and now forms, with the upper, an angle of 135°.

Dec. 24. The extension of the arm still continues increasing. The wounds are healing, but in front of the elbow and above it there is still a pretty large patch of granulations. She seemed so well that I thought she might get up, and directed that the extension should be persisted in, by tying a four-ounce weight to her hand, and leaving it to hang unsupported by her side for ten minutes or a quarter of an hour frequently during the day as she could bear it without much distress. This weight, however, was rather more than she could manage, and a medicine-spoon, about half the weight, was used instead, and was found quite sufficient to tire the muscles and keep up the extension. Is to have a pint of porter daily.

Jan. 24, 1845. Has been going on well, and is capable of carrying the spoon for a greater length of time without annoyance; the wounds much diminished and still granulating kindly. She was yesterday attacked with slight head-ache, and is to-day feverish and has a quick pulse. ℞ *pulv. rhei c. hydr.* ℈j. *stat.*

Jan. 25. Tolerably well again, and the wound not disturbed.

Feb. 26. Still going on well; the wound healing slowly; the arm still straightening, and, as she has not yet made any attempt at bending, it is pretty stiff. I therefore desired that she should begin to do so, and also that she should carry occasionally heavier weights, which, indeed, she is disposed of her own accord to do.

March 7. Is beginning to bend the elbow a little, and since the last report carries with the right hand a two-gallon can of beer up a flight of stairs with little trouble. Is to exercise her arm by pulling a weight over a pulley fixed above her.

March 11. The long wounds upon the fore arm are all but healed. Upon the inside of the upper arm from the elbow upwards is a granulating wound, about two inches long and an inch and a half wide, which is granulating kindly; but its healing seems retarded by the pull of the broad scar which deepens the back edge of the arm-pit. This I propose soon to set at liberty, by cutting vertically through its connexion with the trunk, and inserting a piece of skin from the back.

In mentioning this case it must not be supposed I consider its success decisive; whether it be so or not requires many months to prove, and depends, I believe, considerably on the favourable result of the proposed plastic operation. It has, however, gone on so very satisfactorily, that I have ventured to relate it here, and I hope in a future part of this work to mention the result.—J. F. S.

Professor Mütter (*a*), a very intelligent surgeon of Philadelphia, has proposed the performance of plastic operations for the relief of deformities from burns, and has thus operated successfully in six out of seven cases, the first three of which he has published. All these were cases of forward contraction of the neck, with depression of the lower jaw, and eversion of the lip. His operation consisted in cutting across the middle of the scar, commencing in the sound skin on one and terminating in the sound skin on the other side of the neck, so that it was "about three quarters of an inch above the top of the sternum," * * * his object in making it so low down being "to get at the attachments of the sterno-cleido-mastoid muscles," both of which it was necessary to divide in the first, and one only in the second case, before the head could be raised to its natural position; but the head could be raised without dividing either, in the third case. A large gap was thus formed, into which was inserted a corresponding flap of skin, raised from the side of the neck, and from the deltoid muscle, without detaching it above, and fixed by several twisted sutures and adhesive straps. The edges of two-thirds of the wound on the shoulder were approximated with twisted sutures, and over the remainder, which could not be covered by the skin, a warm water pledget applied. The head was kept back by a bandage, and the patient then put to bed. She was not permitted to take "any kind of nourishment, in order that adhesion or union by the first intention might be accomplished," till the third day after the operation, and then only a few spoonfuls of barley water every hour or two. On the third day after the operation the

---

(*a*) Cases of Deformity from Burns successfully treated by Plastic Operations, Philadelphia, 1843. 8vo. Also, in American Journal of Medical Sciences, July, 1842.

dressings were removed, "the wound found united, with the exception of here and there a point and a small pouch of pus at the most depending part of the flap," which was punctured and the pus evacuated. Some of the pins were removed, and fresh straps applied. This the first case succeeded admirably, and the history of the other two which he has published, were nearly counterparts of it. After the incision had healed, the head was supported by "a stiff stock on which her chin rested, and this instrument also served to press the integument back, by which the natural excavation or depth of the neck, in front was readily effected."

With the view of determining the propriety of the operations, such as those reported by him, MÜTTER makes some very interesting and valuable observations on, "1st, the nature of the tissue to be divided or removed; 2ndly, the thickness or profundity of the cicatrix; 3rdly, its location; 4thly, its extent; 5thly, its age; and, 6thly, its peculiar deformity."]

When large burns scar, there not unfrequently arises abdominal disorder, and frequent watery evacuations, which must not be suppressed.

III.—OF FROSTBITE.

Anweisung, alle erfrornen Glieder aus dem Grunde zu heilen, auch dann noch, wenn sie seit mehreren Jahren erfroren sind. 2nd Edit. Pirna, 1804. 8vo.

103. In *Frost-bite*, (*Congelatio*, Lat.; *Erfrierungen*, Germ.; *Congélation*, Fr.,) the severe and continued cold produces numbness of organic parts, so that sensation and motion are diminished, and, if its influence be continued, all sensation and motion are lost, the pulsation of the arteries ceases, and death ensues, in consequence of which the part is shrivelled and dried (1). If the whole body be subjected to such influence, the skin becomes gradually pallid and insensible; from the collection of blood in the internal parts especially in the brain and lungs, arise anxiety, weakness, disposition to sleep, and, if these symptoms occur and the cold continue, death is the result (2). This particularly happens after the use of spirituous drinks without sufficiently active exercise.

[(1) The parallelism of the effects of great degrees of heat and cold upon the animal body is very remarkable; for, though the causes are so opposite and unlike, yet are their results precisely similar, in almost whatever degree they are applied. Thus heat and cold produce only agreeable sensations when not advanced beyond a certain degree; but, if exceeding that, then both become painful without, however, exciting inflammation. A further degree of heat causes vesication, without death of the part, by merely exciting at first sufficient inflammation, or at least sufficiently increased action, to produce immediately the effusion of serum necessary to the formation of a blister. An increased degree of cold acts differently, inasmuch as its primary effect is to suspend the passage of the blood through the vessels, whence arise the blueness and puffiness of the cooled part, which is still painful, and has its motions restricted. But, if the cold be continued, the part becomes pallid, or yellowish-white, as if the blood were squeezed out of it, and its vessels emptied; the pain now ceases, the part becomes numb and motionless, but it does not vesicate. When the coldness subsides, the heat not only returns, but exceeds the natural standard; the pain also recurs and becomes more severe; inflammation being thus set up, its termination depends on the mode of treatment followed out. A still greater degree of heat or cold produces mortification, which, when depending on heat, except in the very rare cases where the part is actually incinerated, is most commonly, and at once, superficial, even in burns which are always more severe than scalds. But mortification from severe cold is almost invariably of the whole mass affected, rarely seems to be produced immediately, at least not in this country, but requires the lapse of several hours for even its appearance, and many more before the whole extent of the injured part declares itself dead, the mortification, if of the extremity, commencing with the tips of the fingers and toes, and gradually creeping up so far as the vital powers have been either totally extinguished, or have been so disturbed as to be unable to resolve the inflammation, depending on either the congestion of the vessels, or their acquired imperviousness, into the natural condition of the part.—J. F. S.

Müller (*a*), in drawing a comparison of the effects of heat and cold on the body, observes:—"Both can produce as well a disturbance of the excitability as irritation, inflammation, and mortification. A sudden violent operation of cold upon warm animal parts acts destructively. An extremely cold state is painful, and then numb. In still greater degrees, mortification, local death ensues. In less degree cold, destroying by abstracting heat, produces symptoms of inflammation and irritation in the efforts made by the parts for restoration of their equilibrium. In a moderate degree cold operates momentarily as an excitant; thus, cold water at once reddens the skin, as I have myself experienced in bathing in the river in October; but this was only momentarily, and slight signs of internal disturbance from the abstraction of heat ensued. Cold water, also, in fevers, with a very hot, dry skin, acts often mediately as an enlivening stimulant, and produces that turgor on the skin which warmth excites in cold parts. The secondary effect of continued cold is always a disturbance of the nervous system. The gradual operation of cold up to a high degree throws man into a condition of seeming death, and hybernating animals into their winter sleep by withdrawing their irritability; whilst a great degree of warmth gradually, also, disturbs the functions of the nervous system, but probably by a change; and in sandy deserts, where there is at the same time want of water, produces asphyxia, and causes the summer sleep of amphibians, and of the tenrec in hot climates." (vol. i. p. 86.)

The length of time, during which a part remains cooled, has material influence in regard to its immediate mortification, its deferred mortification resulting from the degree of inflammation excited by the cold, or simply to its inflammation which resolves without mortification. This is proved by **Hunter's** experiments in freezing rabbits' ears (*b*). In one case "the ear remained in the mixture (of salt and ice) nearly an hour, in which time the part projecting into the vessel became stiff; when taken out, and cut into, it did not bleed; and a part being cut off by a pair of scissors, flew from between the blades like a hard chip. It soon after thawed, and began to bleed, and became very flaccid, so as to double up on itself, having lost its natural elasticity. When it had been out of the mixture nearly an hour it became warm, and this warmth increased to a considerable degree; it also began to thicken in consequence of inflammation, whilst the other ear continued of its usual temperature. On the day following, the frozen ear was still warm, and it retained its heat and thickness for many days after." (p. 123.)

I have already mentioned the case of sloughing of the scrotum following the continued use, for a few hours, of ice to further the reduction of a rupture. We have in St. Thomas's Museum, also, the cast of a soldier whose scrotum having been frost-bitten in Flanders, during the campaign in 1793, under the Duke of **York**, both testicles, and a portion of the spermatic cord, were exposed, and long remained without skin, though completely covered with granulations.

Actual frost is not absolutely necessary to produce mortification; cold wet is quite sufficient if continued sufficiently long to reduce the natural heat of the part below a certain standard, and there retain it, as will be presently seen in a case of mortification of the hand from laying out hides, and this more especially when evaporation is going on quickly.—J. F. S.

(2) The interesting account given by Sir **Joseph Banks** (*c*), of the sufferings of himself, of Dr. **Solander** especially, and other of their companions, from exposure to cold is well known, and is quoted by **Thompson**, (p. 619,) who also mentions (p. 620) another remarkable case of Dr. **Kellie's**, which had been previously reported (*d*).]

104. When a limb or active body becomes frozen, the living activity is depressed by the torpidity of the juices, a state of asphyxia is present,

(*a*) Handbuch der Physiologie.

(*b*) Observations on certain parts of the Animal Œconomy. London, 1792. 4to. 2nd Edition.

(*c*) Captain Cook's Voyages, vol. ii. Hawkesworth's Edition.

(*d*) Duncan's Edinburgh Medical and Surgical Journal, vol. i. Edinburgh, 1805.

which is yet susceptible of reanimation, but which, if left to itself, must necessarily run into gangrene or death. Those parts are most commonly affected by the dangerous effects of cold which are most distant from the heart, and in which the evolution of warmth, under natural circumstances, is slight, as the hands, ears and nose; especially if the circulation through them be hindered by accidental pressure.

Hunter (*a*) observes that, in frost-bite, "the effect of the cold is that of lessening the living principle. The powers of action remain as perfect as ever, but weakened; and heat is the only thing wanting to put these powers into action; yet that heat must at first be gradually applied and proportioned to the quantity of the living principle, which increasing, the degree of heat may likewise be increased. If this method is not observed, and too great a degree of heat is at first applied, the person or part loses entirely the living principle, and mortification ensues." (p. 137.)

Astley Cooper (*b*) says:—"In this climate, destruction of the life of the part does not, in general, immediately succeed" the application of a great degree of cold for a considerable time to a part; but "the part will become numbed, that is, its nervous power will be diminished; and, when it is thus enfeebled, it will be unable to bear a very slight degree of inflammation, and the destruction of its life follows. * * * It generally happens that inflammation succeeds the application of cold after an interval of two or three days." (pp. 215–16.)

Larrey (*c*) does not consider, in frost-bite, "the cold as the determining * * * but merely the predisposing cause" of mortification; and observes, in support of this opinion, that, at the time of the battle of Eylau, the French soldiers "did not experience any painful sensation during the severe cold (varying from 10° to 15° below zero of Réaumur's thermometer) to which they had been exposed on the night-watches of the 5th, 6th, 7th, 8th, and 9th of February, 1813; and that it was not till the night of the 10th, when the temperature had risen from 18° to 20°, (a great quantity of sleet having fallen," as he mentions previously, "on the same morning, and been the forerunner of the thaw which took place in the course of that day, and continued in the same degree for several days,) that they felt the first effects of the cold;" and "applied for succour, complaining of acute pain in the feet, and of numbness, heaviness, and prickings in the extremities. The parts were scarcely swollen, and of an obscure-red colour. In some cases, a slight redness was perceptible about the roots of the toes, and on the back of the foot; in others, the toes were destitute of motion, sensibility, and warmth, being already black, and, as it were, dried." (pp. 60–2.) Larrey's objection to the cold being the determinate cause of the mortification, is not borne out by this account; for it is well known that the cold produced during a thaw is much more severe from the accompanying evaporation, than whilst freezing continues. It may be also observed, that a greater degree of dry cold than of wet cold can be borne without inconvenience or danger, as our daily experience proves in dry frosty and cold wet weather.—J. F. S.

The two following cases, for which I am indebted to my friends and colleagues Green and Solly, under whose care they were, present good examples, the first, of the usual result of frost-bite in this country, and the second, of mortification from continued application of cold moisture in an excitable constitution, arising from the use of beer and spirit:—

Case 1.—J. W., aged thirty-nine years, was admitted into St. Thomas's Hospital.

Dec. 15, 1829. He has followed various occupations, but has, in general, lived poorly; and has now mortification of both feet, of which he gives the following account:—

About a month since, being very destitute, he lay for four successive nights in the open air, at which time the weather was very cold. On the morning following the fourth night, he found himself, on rising, unable to stand from loss of sensation in his feet, and unconsciousness of touching the ground. He was removed by the police to Cold Bath Fields' Prison, where he states that, for some time, he was fed on gruel and on soup on alternate days. Soon after his arrival at the prison, the numbness of his feet was succeeded by a warm pricking stinging heat, and this soon followed by redness, swelling, and throbbing of the parts. He does not remember what treatment he was subjected to, but these symptoms, accompanied with great pain, continued for eight days; after which, in the course of a single night, both feet mortified, assuming an ashy-black colour, and here and there having small vesications. Simultaneously with this change, the pain remitted, and, in a day or two after, the line of separation between the dead and living parts appeared. He continued in the prison infirmary, the separation advancing, and his health varying but little, until his admission here.

(*a*) As just quoted. (*b*) Lectures on Surgery, vol. i. (*c*) As quoted above.

The entire soles of both feet, and the front of both as far as the tarso-metatarsal joints, were completely mortified. A line of healthy granulations divided the living from the dead parts in both feet nearly alike; in both, commencing from the metatarsal bone of the great toe, it crossed the bases of the other metatarsal bones to the outer edge of the foot, along which it stretched backwards beneath the outer ankle, around the heel inwards, and thence forward to the base of the great metatarsal bone. The sloughs were very offensive, and he complained of great pain and want of sleep. Pulse 90, feeble; appetite good; bowels confined; tongue moist and slightly furred. ℞ *ammon. carb.* gr.v. *conf. aromat.* ℈j. *tinct. opii.* ♏x. *mist. camph.* ℥jss. 6*tis.* He is to have meat, with half-a-pint of porter; sago, with a glass of port wine daily. The feet are to be wrapped in rags steeped in *lot. calc. chlor.*, and a poultice to be applied over.

Dec. 16. Has had a restless night; has a quick full pulse, head-ache, and a furred tongue, probably from repletion, he having been allowed to take meat, porter, sago, and wine at once, and his bowels being unmoved. The meat was, therefore, ordered to be discontinued; and a dose of *mist. senn. comp.* to be taken immediately, and repeated three hours after, if necessary.

Dec. 19. Has been relieved by the clearance of his bowels, and is better; but he complains still of want of rest. *Omitt. mist.* ℞j *opii.* gr.j. *t. d.*

Dec. 22. Still complains of great pain, but the separation is proceeding rapidly, and the dead parts seem held only by two or three of the metatarsal bones.

Dec. 26. To hasten the cure, it was thought advisable to remove the right foot, which having separated at the tarso-metatarsal joint of the great and little toes, the three middle metatarsal bones were sawn through about half-an-inch from their base, following the line of demarcation. The knife was carried along the sole of the foot, dividing two tendons, to the heel-bone, the tuberosity of which was divided by ulcerative absorption; and, with a few slight touches of the knife, the whole of the mortified parts were removed. A slight arterial bleeding occurred at the heel, but was soon arrested by pressure. A poultice applied. ℞ *ammon. carb.* gr.viij. *conf. aromat.* ʒss. *mist. camph.* ℥jss. 6*tis. op.* gr.j. *sexta quaque hora.*

Dec. 28. The left foot removed nearly as the right, but the three inner metatarsal bones, and the tuberosity of the heel-bone required sawing through.

Jan. 25, 1830. Continues improving in health; cicatrization goes on slowly. *Omitt. mist.* ℞ *opii.* gr.j. *quin. sulph.* gr.ij. *ext. gent. comp.* gr iij. *ter in die*, a pint of porter daily.

Feb. 8. Cicatrization in the left foot has proceeded rapidly, the stump having nearly skinned over; but, on the right foot it is tardy, and the exposed part of the heel is about to exfoliate.

Feb. 28. The exfoliated bone was removed.

April 3. The left stump is healed. The right has varied a little, according to the state of his health; but to-day three dark spots, corresponding to the points of the sawn-off metatarsal bones, have appeared. By the beginning of

October, A very indolent ulcer occupied the plantar surface of the remaining part of the foot; and, showing no disposition to heal, amputation is talked of. Superficial indolent ulceration of the extreme part of the left stump had taken place, but seems now disposed to improve.

Dec. 10. The right leg was amputated, by the circular incision, below the knee, and three ligatures applied.

Dec. 14. Stump first dressed; going on well.

Jan. 2, 1831. The wound nearly healed, but the ligatures have not come away. They separated, however, on

Jan. 4, One; on 10th, one; and on 13th, the last came off.

March 30. The ulceration on the left foot, which, at the time of the amputation, was only as large as sixpence, circular, and surrounded by a hardened edge, has recently spread over the whole sole, without any obvious local or constitutional cause.

June 1. The ulcer healing, but not reduced to its first size. Amputation was proposed, but declined.

Case 2.—T. B., aged thirty years, a tanner, was admitted

Feb. 3, 1845. He has been accustomed to live freely, and taken largely of beer, with the addition of spirits occasionally; but has enjoyed good health till within the last three months, in which he has head-ache, and been under the care of the out-patient physician, by whom he has been cupped on the neck and purged freely, but without benefit.

On the 24th of last month he was engaged, under cover, during a cold day laying out fresh hides till dinner-time, an occupation which kept his hands continually cold and wet. His dinner did not occupy him ten minutes; and his hands during that time having continued still cold, he returned to his work, and for five hours during the afternoon was engaged cutting off the horns from the hides, whilst he held the latter in his left hand. Towards the latter part of the afternoon he felt cold all over, and, when he had returned home, feeling his left hand very cold, and being unable to straighten his fingers, which had stiffened as he held the skins; but neither the fingers nor hand were yet discoloured. He put his hand into lukewarm water; but could not bear it immersed on account of the great pain excited, which was also brought on by holding the hand to the fire. Indeed, he was only easy when the hand was cold, and could not even bear it beneath the bed-clothes, but was obliged to keep it out upon the counterpane. Before putting his hand and arm into warm water, there was not any apparent change in colour; but, after the first and every succeeding dipping into warm water, the hand became red and redder, and more painful.

On the 25*th ult.*, when he awoke in the morning he noticed the nails were blackening about their roots; but he was free from pain, though the hand was very cold and numb, and was not prevented going about a little job.

On the 26*th* he again tried immersion in warm water; but the pain recurred, and the terminal joints of all the fingers and thumb had now become black. The mortification continued spreading; repeated applications of warmth always excited pain, and he was more easy in proportion to the part being kept cold.

On the 30*th* the mortification, having continued along the fingers, just entered the palm, and he began to suffer constant pain.

On *Feb.* 2, the hand had mortified up to the wrist; the pain was so gnawing and severe that he could not rest, and was accompanied with severe head-ache. He applied to a medical man, who bled him twice in the same day from the ailing arm, but did not get more than a pint of blood, and ordered warm applications.

Feb. 3. During the last night the gangrene had extended about one-third of the forearm upwards; has a dark colour, which terminates abruptly; is perfectly cold and insensible. He complains of pain in the head, aching and weariness of the limb, loss of rest at nights, general weakness, and failing appetite; he suffers much from thirst; his tongue covered with white fur, and the bowels confined; pulse 120, regular and weak, but perceptible at both wrists. A dose of infusion of senna with sulphate of magnesia was ordered forthwith; meat, and a pint of porter daily; warm fomentations and linseed-meal poultice to be applied to the hand.

Feb. 4. Altogether more comfortable. The bowels have been freely relieved; his tongue is cleaner, and the head-ache lessened. Is to have four ounces of brandy and two pints of porter daily.

Feb. 5. Is much the same; but feels very weak, though his appetite is improving. No pulsation can to-day be felt in the wrist of the ailing arm. The heart was carefully examined to-day, and its action and sounds ascertained to be natural. Is to have a mutton chop and two eggs, with three pints of porter, daily. ℞ *tinct. opii* ♏xx. *sp. ammon. comp.* ʒj. *ex mist. camph. 6tis.*

Feb 15. The gangrene has not spread since the last report; the line of demarcation between the living and dead parts is now apparent, and some vesication has occurred round the arm. The ulcerative process has continued steadily, and has now,

March 8, completely passed through the soft parts down to the bones, forming a regular well-shaped stump, the whole of which is granulating kindly. The gangrenous part has much the appearance of brown paper, and, though a little shrivelled, keeps its form, but is very offensive. It was therefore thought advisable to saw through the dead bones and remove it, which was done accordingly. His health has been steadily improving; he has scarcely had an untoward symptom, his head only aching occasionally; he sleeps well, and enjoys his food.

March 31. Wound cicatrizing, and there seems every prospect of his doing well.]

105. If a part frozen or benumbed by cold be too suddenly warmed, severe inflammation is the result; the part swells, becomes red and blue, and active throbbing pain ensues—*chilblains;* pouring out of fluid into the cellular tissue, suppuration, and, in actually frozen parts, *gangrene.* Corresponding appearances occur on the whole body if warmth be applied after exposure to severe cold; the skin swells, becomes red and painful, red spots, gorging with blood in different parts, and, in consequence, swimming of the head, swooning, spitting of blood, inflammation of the lungs, and so on. The hasty warming of a thoroughly benumbed body produces death and rapid putrefaction.

[**Astley Cooper** observes on this point:—"Great care must be taken in these cases not to apply heat very suddenly; even the common heat of the bed frequently occasions inflammation, which is extremely liable to gangrene, in consequence of the diminished nervous influence of the part:" and he mentions the case of a person who "had been shooting, and had exposed himself to severe cold; and finding his feet benumbed on his return, he immediately put them into warm water. The consequence was that a gangrene took place, of which, notwithstanding every care, he died." (p. 216.) **Larrey** also observes that those soldiers who had been exposed to severe cold, and had opportunities of warming themselves, suffered most. The cases just related confirm these statements.]

106. In reanimating a frozen person we must always commence with the lowest degree of warmth. The frozen person should be brought into a cold room and covered up (after he is undressed) with snow or with clothes dipped in ice-cold water; or he may be laid in cold water, so however that his mouth and nose are free. When the body is somewhat thawed, there is commonly a sort of icy crust formed around it; the patient must then be removed, and the body washed with cold water mixed with a little wine or brandy. When the limbs lose their stiffness and the frozen person shows signs of life, he should be carefully dried; put into a cold bed in a cold room; scents, and remedies which excite sneezing, are to be put to his nose; air is to be carefully blown into the lungs if natural breathing do not come on; clysters of warm water with camphorated vinegar, tickling the throat with a feather, dashing cold water upon the pit of the stomach. He is to be brought by degrees into rather warmer air; mild sudorifics, elder and balm tea, with solution of acetate of ammonia, warm wine and so on, are to be given, in order to cause gentle perspiration.

107. In a similar way a frozen limb is to be thawed; it is to be rubbed with snow or dipped in cold water, till sensation and motion return, when it may be washed with camphorated spirit, brandy, petroleum or essence of amber; cold, mild sudorific tea may be given to the patient, who is to be put to bed in an unwarmed room, with a view to keeping up a gentle perspiration for several hours.

Frozen parts must always be handled with care, and no violence used, because they easily break.

108. When by hasty warming a frozen limb becomes much swollen, painful, red, blue, or in some parts even black and shrivelled like a mummy, and to outward appearance is mortified, it may, however, still be oftentimes recovered by the application of cold, and by gradual transition to warmth. But, if *mortification* have already taken place, its usual treatment must be employed. If superficial, the slough separates; but, if the whole mass of the limb be affected, so soon as the mortification is defined, amputation must be performed.

In many cases the mortified limb drops off, of itself, or the bone only has to be sawn through at the point of demarcation. It does not, however, follow that in this mortification amputation is to be rejected. My own opinion as to the fortunate results of amputation performed at the proper time, and the disadvantage of delaying it, agree with those of **Larrey** (*a*).

109. *Chilblains* (*Perniones*, Lat.; *Frostbeulen*, Germ.; *Engelures*, Fr.) are erysipelatous inflammations of the skin, which, according to their degree, are accompanied sometimes with slight swelling and sensation of heat and pricking, which after a little time often subside of themselves. Sometimes they are connected with considerable dusky-red or bluish swellings and severe pain; sometimes with excoriation, arising from

---

(*a*) As above, 72.

little blisters or risings of the skin, and are often converted into wide-spreading obstinate sores. Chilblains may also, by great neglect, become mortified. They produce, only in winter, especially in change of weather, annoyances which are often great, and even interfere with the use of the limb; but, in summer, they subside. In any dyscracy of the body they often assume a corresponding character.

[Hunter mentions "another inflammation very like chilblains, which is not very lively and is often in blotches, some the breadth of a shilling, others of the breadth of half-a-crown, and even broader, &c. This inflammation certainly arises from irritable debility; the blotches look more of a copper colour, and the skin over them is often diseased." (p. 265.) I have seen this appearance several times, and, in two or three instances, long streaks in the course of the superficial veins of the same character.—J. F. S.]

110. Chilblains usually occur in young weakly persons, and women who are not accustomed to cold, have a sensitive and delicate skin, most commonly on the feet, hands, ears, nose, and lips, by a sudden alternation of cold and heat, especially if the part be moist and sweating. In many persons there seems a peculiar disposition for their production.

111. The treatment of chilblains of a mild kind consists in frequently rubbing them with snow, in repeated washing with ice-cold water, with brandy and water. camphorated spirit, lead wash, vinegar, acetate of ammonia, solution of hydrochlorate of ammonia, tincture of amber, diluted hydrochloric or sulphuric acid, petroleum, oil of turpentine, a mixture of rectified spirit of ammonia and laudanum, nitric acid with cinnamon water, solution of chloride of lime and so on. If they are very painful, more soothing remedies must be employed, leeches on the diseased part, cocoa, butter, deer-suet, poultices of chamomile and elder flowers, of rotten apples,bruised houseleek, various softening ointments, smearing with warm glue, and so on. Rubbing in soap liniment with a portion of tincture of cantharides upon the chilblain once or twice a day and keeping it warm, and, if it be ulcerated, the rubbing is to be applied in the immediate neighbourhood (*a*). The diseased part must be kept warm and quiet during the employment of these remedies.

[One of the best stimulants for chilblains is our hospital mustard liniment, consisting of one ounce of flour of mustard to a pint of turpentine.—J. F. S.]

112. Ulcerated chilblains require drying salves, lead oinment, zinc ointment, with myrrh, camphor, opium and Peruvian balsam, red precipitate of mercury ointment, and, if the flesh fungates, it must be touched with lunar caustic. In old sores of this kind, issues must be employed before they close, and, if connected with any general disease, it must be properly counteracted. Many speak favorably of electricity.

Gangrenous chilbains must be treated after the general rules.

113. The occurrence, as well as the recurrence of chilblains, must be guarded against by accustoming oneself to the cold, by avoiding warm coverings, and all hasty warming of cold parts, by frequently washing with cold water, and afterwards brushing and carefully drying them.

114. The *Boil* or *Furuncle* (*Furunculus*, Lat.; *der Blutschwär* oder *der Furunkel*, Germ.; *Furoncle*, Fr.) is a hard, bounded, deep red, raised and very painful swelling, situated in the sebaceous follicles of the skin, occurring on all parts of the body, and usually terminating in suppuration.

A slight pain first attacks some one part of the skin, and a little swelling appears, which, as the pain increases, becomes elevated, hard, and of a deep red colour, and attains various degrees of size, rarely, however, exceeding that of a pigeon's egg. In delicate persons, and in children, or, if the boil be seated in a sensible part, febrile symptoms often arise, loss of sleep, want of appetite, convulsions and so on. The swelling becomes white at the top, it breaks, some pus mixed with blood is discharged, and then the bag of the gland together with the destroyed cellular tissue is thrown off like a grayish-white core, or *set-fast*, as it is vulgarly called, (*Eiterpropf*, Germ.; *Bourbillon*, Fr.,) after which the surrounding hardness subsides.

The sebaceous glands of the skin are not contingently attacked by the inflammation in boil, if the furuncular inflammation of the cellular tissue occur in its neighbourhood (**Walther**); but the sebaceous glands are originally the seat of the inflammation, and from them the inflammation spreads into the surrounding cellular tissue, as is proved by the little hard knot out of which the boil is always developed. The boil is only one link in the changes of the sebaceous glands, produced by inflammation, and only a gradual variation from the pimples and red spots so frequent on the face. These pimples, the mere inflammation of the excretory ducts of the sebaceous glands, may be always easily removed and their passage into a little pustule prevented, if they be squeezed early, which discharges a tallow-like substance from the duct. As the pimples are connected with the boil, as inflammatory affections of the sebaceous glands and their ducts, so also the maggots (*commedones*) are plugs in the excretory ducts, and the little pearl-like, almost transparent vesicles, which often occur in great numbers on the face of persons with tender skin, and which, if cut into or pulled out, present a tallowy substance enclosed in a bluish-white bag beneath the skin, to the sebaceous tumours—as chronic changes of the sebaceous glands.

[**Gendrin** (*a*) denies that cores are sloughs, but says they are morbid secretions or pseudo-membranes, the product of the inflammation of the inter-areolar cellular processes; and that they consist of a viscid semi-transparent homogeneous yellowish-white substance without any vessels and without the least trace of organization. (p. 19.)

Boils are divided by **Alibert** (*b*) into four kinds, each presenting special characters. 1. The *Common Boil* (*Furoncle Vulgaire* or *Clou*) described above. 2. The *Wasp's-Nest Boil* (*Furoncle Guêpier*) is also called by some the *Malignant Boil*, and by others the *Mild Carbuncle*, though they only described *Malignant Carbuncle:* the two diseases, however, appear to **Alibert** decidedly distinct, and justify their separation and the arrangement of the so-called mild carbuncle with boils, of which, indeed, it is merely an agglomeration, indicated by a hard tumour surrounded with a red and inflamed zone, and having its top covered with one or more vesicles which shew its serous character: the pain is severe, the heat pungent and burning; pulsation and fluctuation are soon felt; the skin thins, and, numerous perforations being formed, a kind of grayish sanious skin separates in flakes, or may be removed in pieces, and the tegument covering the tumour separates during its course. This form of boil generally attacks the nape and region of the neck,

---

(*a*) Above cited, vol. i.

(*b*) Quoted at the head of the article.

sometimes extends to the back and rump, and even occasionally attacks the upper limbs. When the parts confining it are set at liberty, large ulcerations occur. It is generally critical; specially occurs after gastric and adynamic affections; rarely attacks other than elderly persons, and hence has been called *Old People's Boil.* According to MALVANI, its course is less quick than that of the common boil; it suppurates more slowly, for vesicles do not appear on it till the third or fourth week. 3. The *Pustular Boil* (*Furoncle Panulé*) is a slightly elevated but wide swelling similar to a pustule. It is acccompanied with pain, distension, and often with slight fever. It proceeds very slowly, requiring many months, and even a year to bring it to perfection. The aperture on its top resembles that of a weaver's shuttle; subsequently the boil dries up, and, if scratched, falls into powder. It occurs in all parts of the body, and, on its subsidence, leaves an ecchymosed spot, similar to that which ushers in its appearance. Its tip is generally red, hard, very shining, and gives place to a slight serous exudation, which ceases for some time, is repaired at intervals, but the hardness continues and is only resolved by furfuraceous scales. 4. The *Asthenic Furuncle* of Dr. COPELAND (*a*) (*Furoncle Atonique* of GUERSENT) (*b*) was described in the spring of 1823 by both those physicians. They agree in having observed it in children previously much weakened by disease; in persons who are subject to gastro-enteritis with adynamic symptoms; in latent pneumonia, during the course of small pox, and so on, according to GUERSENT, and where the weakness has been caused by chronic disorder of the bronchi, or asthenic inflammation of the substance of the lungs, according to COPELAND, who adds that coma generally comes on before death, in addition to the well-marked symptoms of adynamia noticed by him and GUERSENT. The eruption appears chiefly on the trunk, the lateral parts of the neck and thighs, but, GUERSENT says, more rarely on the limbs. COPELAND states, that in the cases he has observed, " the number of furuncles has been considerable, not fewer than five or six, and in two cases they were about twenty. GUERSENT'S paper, however, does not lead to the supposition that in his cases the furuncles were numerous. Both describe them to begin as circumscribed swellings, of little extent, but resistant to the touch, of a livid violet colour, but sometimes without any remarkable change in the colour of the skin. In the second stage, a very small purulent phlyctæna appears on the top of the swelling, and, when it tears, the true skin shows beneath a little grayish patch, softened and perforated through and through like a common boil. At first a bloody serous fluid exudes, the swelling softens, and the aperture in the skin enlarges, which in two or three days, and sometimes even in twenty-four hours, forms a perforation from five to six lines in diameter, completely round, and exactly like a hole which has been made with an auger. During this time the swelling rapidly subsides. The cellular tissue does not separate like a core, and rarely detaches some fragments. The bottom of the ulcer presents a grayish sanious and dryish appearance, and whilst its edge is well defined, the surrounding skin, paler and softer than natural, is entirely separated from the cellular tissue to the extent of several lines. This atonic furuncle very commonly follows leech-bites; the perforation in the skin then seems to have been made with a trocar, but this triangular form soon rounds as it spreads, and becomes completely circular, as if it had arisen spontaneously. If the leech-bites have been grouped together, and each bite have given rise to a little furuncle, the skin after a few days appears perforated at every bite, and resembles a suppurating carbuncle, but with this difference that there is neither fulness nor swelling, and that the holes are larger and more regular than in carbuncle, such as might be made by small shot. The ulceration, which is the third stage of atonic boil, is generally indolent; in some cases, however, it is painful. It remains stationary for eight or ten days, more or less, according to the general condition of the patient. When the ulcer is disposed to heal, the cellular tissue becomes moist, brightens, and becomes slightly reddened, the skin gradually attaches itself to the subcutaneous tissue; some fleshy granulations rise from the bottom of the ulcer; the aperture in the true skin diminishes a little, and, as in all ulcers of the skin, a soft scar, slightly depressed, is produced, and which, in its extent only may be compared to that succeeding a large vaccine pustule." (pp. 337, 8.) In addition to these observations of GUERSENT, it is noticed by COPELAND that the cellular tissue is destroyed by rapid ulceration or phagedenic absorption; that the ulcers have no discharge nor any tendency to scab; that, in the two cases he examined after death, no attempts at reparation were visible in the ulcerated perforations, nor any injections nor inflammatory appearances in the margins: the chief alterations were moderate emaciation, congestion, and injection of the membranes of the brain with slight serous effusion, congestion of the substance of the lungs, with limited hepatization in an early

---

(*a*) Above quoted.

(*b*) Du Furoncle Atonique; in Archives Générales de Médecine, vol. i. Jan., 1823.

grade; patches of injection in the digestive mucous membrane, other parts being pale; and enlargement of the mesenteric glands. * * * The perforations are always uniform in character, although varying somewhat in size; they are peculiar and hardly ever modified from the state described; they appear analogous to the perforating phagedenic or atonic ulcers sometimes seen in the stomach. (pp. 1054, 55.) GUERSENT further remarks, that "this disease is evidently allied to the boil in its first and second stages by its form and mode of opening: the softening and sinking of the tumour after suppuration, and the absence of core, approximate it to certain kinds of atonic abscess; but the other characters do not permit their arrangement together. Finally, it is distinguished from all other cutaneous inflammations by the round and regular form of the ulcer which succeeds it. The kind of perforation has something specific; it can only be compared to the spontaneous opening of the atonic abscesses sometimes noticed on the sides of the neck, in which serous bad pus has long separated the skin before it softens it. The opening of those abscesses, often very large, and increasing as rapidly as atonic furuncle, independently of their difference in the first stage, never exhibit those regular ulcers seen in atonic furuncle." (p. 338.)]

115. The boil often occurs in healthy persons without any apparent cause. It frequently appears in convalescence after severe fever, is not unfrequently critical; after suppressed perspiration from neglect of cleanliness of the skin, in persons who live irregularly; during menstruation, and in the spring. Boils often appear, probably dependent on the state of the atmosphere, especially in young persons, in great number, at greater or less distance, in different parts, and are commonly accompanied with severe fever. After the misuse of mercury, persons with deteriorated juices, syphilitic, scrofulous and scorbutic, are frequently subject to boils. In these cases they are often chronic, attended with little pain and tedious in suppurating.

116. The treatment consists in furthering suppuration, for which purpose, in very painful boils, softening poultices with the addition of henbane, bruised poppy heads, or, in moderate inflammation, roasted onions, flour and honey, the *empl. de cicut. c. ammoniaco*, the *empl. diachylon. comp.* are used. In most cases the boil opens itself, or it may be opened with the lancet, the slough or core separates by the use of softening bread poultices, which should be continued till all hardness subsides. If any hardness remain, it is usually only dispersed by a fresh inflammation and suppuration, which we must endeavour to excite. If the boil be accompanied with very painful tension, this may be relieved and the entire course of the disease cut short by an incision throughout its whole length, and the use of softening poultices.

[In treating boils, as in the treatment of carbuncles, it is certainly best to cut across them at once, freely and deeply; the momentary pain is severe, but the relief from the violent pain under which the patient suffers is almost immediate; the tension of the part is at once relieved, the cellular tissue being enabled to discharge the serum with which, intermingled with adhesive matter, it is loaded, and thus its destruction is arrested, and the increase of the core put a stop to, and not unfrequently even does it entirely disappear, so as to render it doubtful whether it have been formed. Almost immediately after the slough or core has been thrown off, a very free flow of serum takes place from its boundary walls, and, in strong constitutions, within a few hours, the large hole from which the slough had escaped, and the surrounding swelling disappear, by the dropping down of the skin and cellular tissue to its own natural situation, leaving only an aperture in the skin which speedily scabs and heals. It is a very common but very improper practice to use stimulants, either in the shape of poultices or plasters. Generally moist warmth, kept up by poultices, by steaming, or wet flannel covered with oiled silk, is most grateful to the patient's feelings; but, in some cases, dry warmth, either with repeated hot flannel, or chamomile flowers in a flannel bag, gives most ease before the boil is opened.—J. F. S.]

117. General treatment in boils is rarely necessary; if connected with gastric impurities, or with acidity, as a cause, these must be corrected by suitable remedies in addition to the local treatment.

Ritter has a one-sided notion of the origin of boils from retention of the animal refuse, and of their dispersion by the early application of cupping-glasses (*a*).

[I do not agree with **Chelius** that general treatment in boils is unnecessary; when such is the case it is the exception, not the rule. Most commonly the general health is disturbed, and requires putting to rights by attention to the hepatic functions, and the proper employment of tonics.—J. F. S.]

118. *Carbuncle* (*Carbunculus*, *Anthrax*, Lat.; *der Karbunkel*, Germ.; *Charbon*, Fr.) is an inflammation of the skin and underlying cellular tissue, with considerable hard swelling, which runs into gangrene throughout its whole extent. It is distinguished from boil only by the severity of the inflammation and by its great disposition to run into gangrene; and from malignant pustule (*par.* 34), with which it has great similarity, and has been by many confounded, in that the latter is always the consequence of an imparted peculiar poison.

Under an attack of severe burning pain, a circumscribed hard swelling is produced, on which numerous pustules arise; these bursting, many sieve-like holes are formed in the skin, from which bloody ichor escapes, and at the bottom of which mortified cellular tissue is seen; the skin grows dark, blue, or black, and quickly runs into gangrene. Sometimes the deep parts are all in a state of mortification before it appears externally. If the skin be destroyed by running together of several apertures, or by mortification, the dead cellular tissue appears as a whitish-gray lump, or, in large carbuncles, as a black, dry mass intermixed with grayish-white and bloody shreds, with great surrounding inflammation, which runs into suppuration, in which case, after the throwing off of the dead cellular tissue a large ulcer is produced, at the bottom of which muscles, tendons, bones and even more important organs, are laid bare. The size of the carbuncle is very different, often as large as the hand, often still larger. It usually occurs on the neck, between the shoulder-blades, upon the back and buttocks. Fever very commonly precedes carbuncle, or accompanies it from the first; and is sometimes only slight, sometimes nervous, putrid and so on. Hence arises the difference between *symptomatic*, *malignant*, *pestilential*, *idiopathic*, and *benignant* carbuncle.

["The inflammation that produces the carbuncle is," says J. **Hunter**, "of a different nature from any of the former; it is stationary with respect to place, and is pretty much

---

(*a*) In Journal von **Graefe** und von **Walther**, vol. iii. part. i. p. 81.

circumscribed, even forming a broad, flat, firm tumour; it begins in the skin, almost like a pimple, and goes deeper and deeper, spreading with a broad base under the skin, in the cellular membrane; and, although considerably tumefied, yet this does not arise from the extravasation of coagulating lymph producing adhesions which are to retain life, for the very cells into which it is extravasated become dead. It produces a suppuration, but not an abscess, somewhat similar to the erysipelatous, when the inflammation passes into the cellular membrane; for, as there are no adhesions, the matter lies in the cells where it was formed, almost like water in an anasarca; but still it is not diffused through the uninflamed cellular membrane, as in the erysipelatous, for it appears to extend no further than the inflammation. One would almost imagine that there was a limitation to the extent beyond which this species of inflammation could not go, and at these limits the adhesive inflammation took place to confine the matter within the bounds of the carbuncle. A diffused ulceration on the inside, for the exit of the matter, takes place, making a number of openings in the skin." (pp. 272, 3.)

HUNTER's observations, that "there are generally more carbuncles than one at the same time, a great number succeeding each other, which would almost seem to produce each other in this succession," I cannot, from my own observation, confirm. Generally I have noticed them to occur singly, but occasionally there may be more.—J. F. S.

The carbuncle "appears," says the same writer, "to have some affinity to the boil; but the boil differs in this respect, that it has more of the true inflammation, therefore spreads less, and is more peculiar to the young than the old, which may be the reason why it partakes more of the true inflammation." As to the causes of the disease he observes:—"As death is produced in a great deal of the cellular membrane, and, I believe, in it only, except the skin giving way, which I believe is by ulceration principally, it becomes a question whether this mortification arises from the nature of the inflammation, or rather from the matter being confined in the cells of the cellular membrane? I suspect the latter; for, I find that if this matter escapes from these cells, and comes into uninflamed cells, it produces mortification there." (pp. 273, 4.)

COPELAND (*a*) well observes:—"Anthrax rarely occurs excepting in habits of body evincing more or less cachexy, with sanguineous plethora, and disorder of the digestive functions. For some days before its eruption, the patient complains of anorexia and increased disorder of these functions, and of lassitude, chills, or shiverings. With the development of the tumour the febrile commotion increases, and presents the usual concomitants of inflammatory fever. If sphacelation takes place, or if the ulceration is protracted, the attendant fever assumes gradually an adynamic character; and, in delicate, old, or very cachectic persons, it is nervous or adynamic from the commencement." (p. 1055.)

PERREZ (*b*) gives the following account of the physiology of carbuncle:—"The malignant carbuncle of ontologique authors is a violent inflammation of the tegument and subcutaneous cellular tissue, produced from an irritation pre-existing in some organ, and most commonly in the organs of digestion, whence it is conveyed to the tissue where the carbuncle is developed. The irritation causing this inflammation is so active and severe that it is almost impossible to prevent the production of gangrene in a more or less large part of the tissue it attacks; but we may, by prompt and powerful antiphlogistic means, arrest the progress of this inflammation, and thus stop the gangrene and other consecutive symptoms. Whatever be the organ whence the irritation causing carbuncles springs, the violent pains, of which the inflamed part is the seat, may reproduce a more or less severe irritation, exasperate that which already exists, and produce in some organ, but most commonly in the stomach, a fresh irritation, all of which may become dangerous if not physiologically contended with. * * * If an irritation be established in an important organ it produces the following effect on the carbuncle:—the irritation, which has caused the latter will be repelled by that of the recently affected organ; the carbuncle becomes pallid, the pains diminish, but the new irritation will increase, and with it the patient's danger. This must be put a stop to, and then the inflammation will reappear on the skin, or even, according as the remedies employed have diminished the disposition to irritation, the inflammation may not reappear. The carbuncle will be averted without the complete cure of the patient being retarded. In some rare instances, this same disposition to irritation will be so great, that the carbuncle and the secondary irritation which it has brought back, exasperated, or produced, will co-exist with equal intensity. The gorging caused by the inflammation is sometimes so considerable, and so very rapid, that it cannot be stopped quickly enough, neither can the tissues stretch sufficiently to avert the strangulation of the gorged parts, and hence results gangrene." (pp. 585, 6.)]

(*a*) Above quoted.

(*b*) Observation d'un Anthrax ou Charbon Malin, traité physiologiquement et guéri; in BROUSSAIS' Annales de la Médecine Physiologique, vol. vii. Paris, 1825.

119. *Benignant Carbuncle* frequently occurs without manifest cause, even in healthy persons; commonly in poor persons, who live in unhealthy neighbourhoods, eat bad food, and are very much reduced by preceding disease; also with impurities of the bowels. Carbuncle is in most cases the consequence of metastasis of deleterious matter (rheumatic or gouty.) It takes place at every age, in either sex, at every season of the year, but especially in the great heats of summer. The *Malignant Carbuncle* is never connected with previous fever.

[English surgeons generally do not hold with the metastatic origin of carbuncle, but believe it rather dependent on disturbance of the digestive organs, or on general disturbance or break-up of the constitution. Thus, it is often noticed in women on the subsidence of menstruation, but more commonly in elderly men who have lived freely and worn their constitutions out. RAYER says that carbuncle occurs most frequently in spring and summer; and our author that it happens especially in the great heats of summer. I have not, however, observed it more common at one than another time of the year.—J. F. S.]

120. The danger of carbuncle depends on its size, seat, on the presence of many such swellings, on the constitution of the patient, and the general disease connected with it.

[ASTLEY COOPER observes:—"Carbuncle generally does well, except when situated on the head or neck. Though persons recover from carbuncles of an enormous size upon the back, yet very small ones on the head or neck will often destroy: indeed, I never saw a patient who recovered from any considerable carbuncle upon the head; in these case there is effusion upon the brain, producing compression." (p. 243.) Carbuncle on th head is rare; I have not seen above two or three cases of it.—J. F. S.]

121. In the *Benignant Carbuncle*, the internal treatment is always guided by the difference of the fever and the cause of the carbuncle. A strict antiphlogistic treatment is rarely indicated, but rather in most cases a mild sudorific treatment, emptying of the intestinal canal, emetics and the employment of dilute mineral acids. When the powers of the patient sink, which always happens on the occurrence of mortification, a more strengthening treatment is needed.

122. The local treatment consists in making very early a cross cut of sufficient depth, by which the constriction of the cellular tissue is relieved. The wound is to be bandaged with stimulating digestive salves, the sloughy cellular tissue to be removed, and an endeavour made to produce good suppuration. If sloughs have formed, still the cuts must be made, or the previous openings enlarged, the sloughs removed, (which treatment is preferable to the use of the actual cautery, butyr of antimony and other caustics,) in order to make an escape for the gangrenous juice, collected beneath them, and to prevent its acting on the whole organism. The further treatment is to be after the rules laid down for gangrene. It is not true that merely softening poultices do harm, and favour the progress of the disease, and repeated experience has proved to me, that, after proper division of the carbuncle by a cross cut, the cure is effected most simply by the continued use of softening poultices.

That cutting into the carbuncle is generally neither necessary nor useful (VON WALTHER) is the most dangerous statement which can be put forth in the treatment of carbuncle. I have often satisfied myself that it was possible by an early cut to preserve the skin, the edges of which, after separation of the mortified cellular tissue, soon healed up; and it is possible only by a proper cut to form an outlet for the collecting gangrenous juice and the dead cellular tissue.

[The practice of cutting deeply into carbuncles is of long standing in this country. WISEMAN, (a) one of our early writers on Surgery, says:—"I advise scarifying or cutting deep into it, (the carbuncle,) to give a breathing to the humour." And perhaps it may be, that to this practice must be attributed the cause of his very remarkable, and to us almost incredible statement:—" I never saw a true carbuncle suppurate." (p. 87.)

(a) Eight Chirurgical Treatises, vol. i. London, 1734.

Bromfield (*a*) recommends injections of bark and tincture of myrrh, but also "strongly inculcates the necessity, at a proper time, of making an opening sufficient to draw out the slough; for, in case you rely on that opening which is generally made by nature, the thin matter only will be discharged, and the sloughed or flocculent membranes will remain, and the orifice close up. When this is the case, how greatly detrimental at present, as well as troublesome in future, it may prove to the patient, every practitioner in Surgery can declare." (p. 129.)

The free incision of carbuncle, generally in a crucial form and deep, was also recommended, years since, by **Cooper**, **Abernethy** and most other English surgeons, **John Pearson** almost alone excepted, for the purpose of relieving the tension of the skin, and thereby diminishing the chance of its destruction, by the burrowing into the neighbourhood of the pent-up ill-conditioned pus, as well as that of the subjacent cellular tissue; so that, although **Dupuytren** has rather more pointedly stated, that "the treatment, like that of all inflammations with strangulation, consists in the methodical employment of incision which must go to the bottom of the carbuncle, and of which the ends must pass two or three times beyond its boundary," (p. 112,) yet our French friends have no right to claim either for him or for **Rayer** the origination of that practice.

After the incisions have been made, stimulating poultices of either port wine, stale beer grounds, or yeast with linseed meal, should be employed to hasten the separation of the slough; which effected, the large hole caused by its voidance must be treated with a common poultice, to encourage granulations; and, if these be sluggish, some gentle stimulant, as lint dipped in nitric acid wash or black wash, may be laid on the sore and covered with the poultice.—J. F. S.

Physick (*b*), of Philadelphia, U.S., recommends, as highly beneficial, the application of caustic vegetable alkali in quantity sufficient to completely destroy the skin when, in the second stage of the disease, the appearance of pimples and small orifices show that the process of making an opening through the skin to allow the dead parts and acrid fluids to pass out has commenced. "In all the cases in which he has used the caustic in this manner," he observes, "the sufferings of the patient ceased as soon as the pain from the caustic subsided. It operates by destroying in a few minutes that portion of the skin covering the mortified parts which, if left to be removed by ulceration, would require several days for its completion, occasioning the chief part of the pain and danger attendant on and consequent to the disease." (p. 175.) If it were necessary for the cure of the disease that the skin covering the dead cellular tissue should also die, then **Physick's** practice would be very satisfactory. But, as the object is to save the skin, which cannot, however, always be effected, though it ought always to be attempted, and in most cases is managed by making incisions through it early, and so relieving the tension which causes the sloughing of the skin, then **Physick's** treatment is decidedly improper.

The use of blisters in carbuncle was also first proposed by **Physick**; but he now doubts their value. He says:—" From the great power of blisters in checking mortification, when proceeding from some kinds of inflammation, I once entertained high expectations of their utility in the treatment of anthrax. But, though I have found them serviceable in abating the burning pain attending the inflammation, they have not shown any power in counteracting its progress to mortification." (p. 179.) **Coates** (*c*), however, thinks "Still there is evidence enough to show that these remedies (*epispastics*) possess a high value in certain cases. * * * Although they may sometimes accelerate rather than retard the mortification of the centre of the tumour, where they very seldom produce vesication, they appear to circumscribe the inflammation, and thus prevent the extension of the disease. (p. 30.) The commencement of the second stage," he says, "is the most suitable time for the use of blisters, and the most fitting cases those where the extent and the situation of the swelling preclude the knife." He also mentions a case in which almost immediately a blister caused a complete line of demarcation where the mortification of an anthrax of the worst kind was spreading rapidly. The swelling was situated on the first cervical vertebra and extended some inches on the scalp, very dangerous cerebral symptoms came on, but yielded readily to the blister. (p. 30.)

(*a*) Quoted at the head of the article.

(*b*) Case of Carbuncle, with some Remarks on the use of Caustic in that disease; in **Chapman's** Philadelphia Journal of the Medical and Physical Sciences, vol. ii. Philadelphia, 1821. 8vo.

(*c*) **Hays'** American Cyclopædia of Practical Medicine and Surgery,—article *Anthrax*, vol. ii. Philadelphia, 1836. 8vo.

Perrez (*a*), who is a disciple of **Broussais**, does not consider incision of a carbuncle sufficient unless it produces free bleeding, and, if it do not, then leeches are indispensable, "the incision merely putting an end to the mechanical cause which adds to the existing irritation; and the latter continuing after, although much diminished by the separation of the slough, requires a persistence in the antiphlogistic remedies to lessen still further and to put it out completely. Marsh-mallow or linseed-meal poultices must be used, and if, from any cause, the inflammation be re-excited, local and general means must be had recourse to. In the case which **Perrez** mentions as having treated on these principles, the advantage gained does not seem so great as he would wish to be inferred. On the first day thirty leeches and on the second fifteen leeches were applied, and the carbuncle covered up in boiled marsh-mallow poultices. The patient was strictly debarred from all solid or liquid food for three days, during which time she was, being of a nervo-sanguineous temperament, well drenched with a quantity of acidulated and gummy drinks. In the following days the sloughs separated, and, as usual, the pain almost entirely subsided. A short time after, the surface again inflamed, leeches were applied around, the wound did well, but, from the recital of the case, although not positively stated, probably not very quickly.

The older surgeons, and even **Pouteau**, employed caustic, and even the actual cautery; but both practices are now completely exploded.]

123. The *Malignant Carbuncle* requires, especially, the proper treatment of its accompanying fever, and the local application of stimulating poultices, even of the actual cautery, or other caustics, if the swelling will not proceed: the other treatment agrees with that already described.

124. *Quinsy*, or Inflammation of one or both Tonsils, (*Angina Tonsillaris*, Lat.; *Kehlsucht*, Germ.; *Esquinancie*, Fr.,) when accompanied by much swelling, interferes with swallowing and breathing; the patients speak through the nose, and are much troubled by the phlegm which collects in the throat. Not unfrequently there is singing and pain in the ears, from closure of the Eustachian tubes. The swollen tonsils are felt beneath the jaw, and seen distinctly when the patient's mouth is opened and the tongue thrust down; and the swelling is often so great as to block up completely the passages of the throat. More or less active febrile symptoms are present, according to the degree of the inflammation.

(*a*) As above.

125. This inflammation originates most commonly from cold in delicate persons unused to exposure to the air, also from any severe irritation of the throat, from spreading of the inflammation from other parts, from the venereal disease, from eruptions of the skin, and so on.

126. In most cases the inflammation of the tonsils is *resolved;* not unfrequently it runs into *suppuration* less indeed as consequence of its own activity than of a peculiar disposition which inflammations of the throat in many persons have to pass into suppuration, more especially if former attacks of the kind have terminated in a similar manner. This may be looked for when the inflammation of the throat has existed for several days with uniform severity, when the sensation of pressure in the throat becomes greater and much mucus is collected therein. The passing into *hardening* is never observed in active, rapid inflammation of the throat, but when it creeps on slowly and recurs frequently; the consequence of which is, a *growth* (or hypertrophy) of the parenchyma of the tonsil gland rather than an actual hardening. The passage into *gangrene* is always dependent on a malignant character of the accompanying fever, and is extremely dangerous.

[Abscess in the tonsil having once occurred, is very commonly again and again produced whenever inflammation attacks the gland, and so quickly that any attempt to prevent its formation is useless, the inflammation rushing, as it were, headlong into suppuration. During its course the agony and inconvenience are very great; but, on the bursting or opening of the abscess, the symptoms as suddenly cease.

Dr. TWEEDIE (*a*) says, that although enlargement of the tonsils results from repeated attacks of inflammation, " it is, however, in some instances congenital, and occasionally appears to be hereditary, and in such individuals it is often associated with traces of the strumous diathesis. The enlargement generally exists without induration of the tonsil, more especially when it occurs in young persons: when it arises as a consequence of inflammation, and more particularly in elderly people, the enlargement is generally accompanied by induration." (p. 185.)

Gangrene of the tonsils is very rare, and in the two cases, both fatal, mentioned by GUERSENT (*b*), it was only attendant on more important disease. In the first case the tonsils appeared to be attacked simply with severe inflammation, and were fortunately relieved by antiphlogistic treatment; but subsequently they became livid, produced a secretion resembling wine lees, and very offensive, and on the seventeenth day the patient died. On examination, besides softening and black or dark-grayish disorganization of the tonsils and soft palate, the same change was found in a portion of the right lung. In the second case, the tonsils were at first but slightly inflamed; on the third or fourth day, however, they assumed a brownish colour, and a very offensive smell, and when cut into were not painful. The patient gradually sunk with vomiting and severe gastro-enteritis, but unaccompanied with much febrile excitement. After death the mucous membrane of the stomach and part of the small intestines were bright red, and in the former covered with a white soft elastic false membrane. (p. 134.)]

127. The *treatment* differs according to the activity of the inflammation and the accompanying fever. In slight inflammation mild diaphoretics are of service, as elder and lime-flower tea, solution of acetate of ammonia, hydrochlorate of ammonia, and so on; in the more active degree, bleeding, application of leeches, nitre in emulsion, calomel. For bathing the inflamed part soothing decoctions are used in form of gargles or injections, which latter more readily clear away the mucus and do not produce any straining of the parts. The inhaling of warm soothing vapours also serves the same purpose.

[Dr. WATSON (*c*) says the only gargle he considers " admissible in the commencement of the malady, is a gargle of warm milk and water. * * * But far better than any-

(*b*) Dict. de Médecine, vol. ii.—Article, *Angine Gangreneuse.*

(*c*) Lectures on the Principles and Practice of Physic, vol. i. London, 1843. 8vo.

thing else, as a local application to the inflamed fauces, is the steam of hot water; whether we are hoping for resolution of the inflammation, or whether we desire to promote and hasten the process of suppuration already begun. * * * The most convenient and effectual inhaler is that of Hercy, from which a large volume of steam is carried inwards against the fauces by the mere natural breathings of the patient." (p. 790.)]

128. In great swelling of the tonsils *scarifications* are specially useful; these are made with the palate-lancet or with a common bistoury, the edge of which is guarded nearly to the point, or with the *pharyngotome.* The patient is to be placed so that the light may fall into his mouth, which is kept open by thrusting a piece of cork between the molar teeth; the tongue is pressed down with a spatula, and shallow cuts are made with the instrument just mentioned into the swollen tonsils. The bleeding is to be promoted by soothing luke-warm gargles.

[In scarifying the tonsils, there is danger of wounding the carotid artery, or some branch, which will continue bleeding and cause serious alarm. Watson mentions in his Lectures a case of fatal bleeding from wound of the internal carotid artery:—"Only a very few years ago, in Ireland, it was struck by a surgeon while scarifying a gentleman's tonsil, and he died in three minutes." In another case, which occurred under Watson's own care in 1838, in which the tonsil glands, during convalescence from scarlet fever, having become so enlarged as to impede breathing considerably, "the surgeon in attendance punctured the tonsils. The next day a good deal of hæmorrhage took place; and this recurred several times, to a considerable and even alarming amount. When the clots that formed were wiped away with a sponge, the blood could be seen welling out in a little stream, with a pulsating motion, from a small incision in the left tonsil. The hæmorrhage was ultimately, after much trouble and anxiety, arrested, by applying a pencil of lunar caustic freely within the bleeding orifice." (p. 792.)

I believe, in such a case, the use of the actual cautery would be preferable to any other remedy, and should certainly employ it if opportunity occurred.—J. F. S.]

129. When the inflammation subsides, but the swelling still continues, astringent remedies, as the *liquor ammoniæ acetatis*, hydrochlorate of ammonia, sage, vinegar, and so on, are to be added gradually to the gargles, by the proper employment of which the disposition of the parts to chronic inflammation is prevented.

130. When an *abscess* forms in the tonsil, which can be distinguished by the above-noticed signs (*par.* 126), by fluctuation on touching the tonsil with the finger, and often by the pus itself showing through, and it does not break of itself under the use of softening gargles, great danger of suffocation, or burrowing of the pus, is to be feared; and it must then be opened with a guarded bistoury, or the pharyngotome, used as in scarification of the tonsils. Irritation of the throat, and straining by vomiting, often effect the bursting of the abscess. After the pus has been discharged, soothing gargles with honey are to be frequently used, and commonly produce a speedy cure. In rare cases the abscess penetrates externally beneath the jaw, and then must be treated as common abscess.

[In reference to the spontaneous bursting of abscess in the tonsil, which generally occurs between the pillars of the fauces, Allan Burns (a) observes:—"But Dr. Brown has informed me that in two patients it burst through the *velum palati.* In both these cases, the sore formed very much resembled a venereal ulcer, and, without great care, in tracing the origin and progress of the disease, would have been mistaken for a venereal affection. I may also mention," he continues, "that where the chief prominence in abscess of the tonsil is seen, not between the pillars of the fauces, but on the fore part of the *velum*, it is not to be expected that the tumour will point as in external suppurations. On the contrary, the pus will continue long deep-seated, and, were the surgeon to delay, in the expectation that it would become more superficial, the patient, before this event took place, would be suffocated. So soon, therefore, as the difficulty of breathing renders it necessary, an opening is to be made in the abscess, and that even where the matter is still deep-seated; but fluctuation, generally obscure indeed, must be felt, before we presume to thrust an instrument into the tumour. If this point be not fully ascertained, a polypus may be mistaken for an abscess of the tonsil." (p. 255.)

(a) Observations on the Surgical Anatomy of the Head and Neck. Edinburgh, 1811. 8vo.

Burns considers that the bursting of a tonsillar abscess is attended with much danger. He says:—"Whenever the abscess bursts, the mouth and fauces are filled by a gush of matter, every obstruction to the free entrance of the air is suddenly removed, the patient fetches an involuntary and deep inspiration, air and matter rush together into the trachea, and death, from suffocation, is almost the immediate consequence." And, in support of this statement, he mentions the case of a strong, active, young man who thus lost his life:—"He had been complaining for a few days of a sore throat, for which he had consulted his surgeon, who had employed the usual remedies. The inflammation terminated in suppuration; the abscess enlarged, till, at length, the tumour occupied almost entirely the fauces; yet, ten minutes before his death, he was walking about the house, restless indeed, anxious, and gasping for breath. The bursting of the abscess and death followed each other so rapidly, that no measures could be taken to prevent the latter event. The cause of death was not conjectured in this instance. The body was examined, and the trachea found deluged with purulent matter. To prevent a similar accident, it would be advisable, where the tumour is large, and the difficulty of breathing great, to puncture the abscess as we would do a hydrocele. Were the matter evacuated through a canula, there would be no risk of its finding way into the windpipe, and, if the stilet were made to project only a little beyond the canula, the trocar may be as safely used as any other instrument." (p. 257, 8.)

In most cases of tonsillar abscess, 'the effort of vomiting excited by emetics is generally sufficient to burst the walls and discharge the pus; but, if this treatment be ineffectual, and the patient's breathing be much interfered with, it is better to open the abscess, for which Allan Burns gives the following directions:—"One who is familiar with the parts in connexion with the tonsil, will, in entering the knife into an abscess here, take care not to direct its point in the line of the angle of the jaw; for, he is well aware, that if he do this, he may injure a large artery. He will push the instrument into the front of the cyst and carry it directly backwards, as if he intended to cut off a segment of the tumour; if he follow this course, and transfix the abscess, the worst which can happen will be injury of the back part of the pharynx, a trivial accident when compared with the effects resulting from opening a large blood-vessel." (p. 257.)

I think, however, that a gum-fleam is the most convenient instrument; its edge should be rested against the enlarged gland, as near the mesial line of the body as possible, to penetrate the swelling and then moved vertically and gently up and down, the handle of the instrument being held like a pen, till the abscess is penetrated, which in general is done quickly, and immediately the pus appears the fleam should be withdrawn. It is recommended, very properly, that the incision or puncture should be made directly backwards or from without, inwards and backwards, to avoid puncturing the internal carotid artery which might be easily done if the knife or fleam were thrust outwards.

The student is always very properly exhorted to puncture tonsillar abscess with great caution, for fear of wounding the carotid artery. But, although this operation must be often carelessly and clumsily enough performed, yet dangerous bleeding is not so frequent as might be expected; and I have only been able to collect the following authentic accounts:—

Portal (*a*) mentions a case in which, in performing this operation with a pharyngotome, "a dexterous surgeon of Montpellier had the misfortune to open a large artery, and see the patient perish of so severe a hæmorrhage that nothing could arrest it." (p. 509.) Allan Burns also says:—"In this country, (Scotland,) I have been informed that a surgeon, in opening a tonsillitic abscess, actually did plunge the knife into the carotid. I need hardly add that he lost his patient before he could suppress the bleeding." (p. 256.) My late colleague Tyrrell was accustomed to mention, in his Surgical Lectures, a case to which he was fetched by a practitioner, who, having punctured an abscess in the tonsil gland, the wound was immediately followed by severe bleeding, and the patient was dead before he could reach the house. Sir Benjamin Brodie informs me that he is cognizant of two cases in which death from bleeding ensued after the puncture of tonsillar abscess.

From the puncture of an immature tonsillar abscess, alarming hæmorrhage may occur, without, however, destroying life; for the following instance of which I am indebted to my friend Lawrence:—

Case.—"In a gentleman labouring under *cynanche tonsillaris*, a premature puncture was made, with the expectation of evacuating matter. A most profuse bleeding ensued,

---

(*a*) Cours d'Anatomie Médicale, vol. v.

which stopped from the occurrence of fainting, and did not recur. It, however, not only seriously alarmed the patient and those around him, but also the gentleman who made the puncture. A long time elapsed before the patient recovered his strength."]

131. When inflammation of the throat passes into mortification, the fever especially must be treated according to its character. The local treatment consists in removing the sloughs and foul ichor from the throat by injection of decoction of bark, of scordium with alum, camphorated vinegar, and so on. Hydrochloric acid with honey applied with a pencil of charpie on the mortified part is of great use.

132. The *hardening* of the tonsils which remains after inflammation, is of a good character; it is little painful, but is commonly subject to repeated inflammatory attacks, yet very seldom does it run into cancer. It may be treated with gargles of hemlock, belladonna, hydrochlorate of ammonia, and so on; by rubbing of mercurial or iodine ointment externally upon the neck, by the internal use of hemlock and by derivation, by repeated scarifications and the frequent use of leeches. If inflammation should occur and run on to abscess, suppuration must be suitably promoted, and the opening of the abscess delayed till all hardness has subsided. In hardening of the tonsils, frequent painting during the day with fresh juice of *chelidonium*, at first mixed with honey of roses, but subsequently pure, is very efficient.

[ELSE (*a*), who, many years since, was Surgeon to St. Thomas's Hospital, denied that this so-called scirrhus of the tonsils was true scirrhus; the tonsils, in his opinion, never being affected with scirrhosity. And TWEEDIE (*b*) observes on this point:—"It is more consistent with pathological anatomy to ascribe those cases of supposed scirrhus of the tonsils to hypertrophy and induration alone." (p. 185.)

A very common attendant on enlargement of the tonsils is a disagreeable roughness of the voice; and deafness also is produced, either by blocking up the apertures of the Eustachian tubes, or by pressing against their cartilaginous part. It has also been asserted within the last few years, that enlarged tonsils are the cause, or one of the causes, of stammering, in consequence of which they have been very freely lopped by the practitioner who broached the opinion, but the success of his operations has been less than he would wish to allow (*c*).

Local treatment with astringent gargles, in these cases, is of little benefit, and painting the tonsils with nitrate of silver not much more efficacious, though it should be tried. I believe that constitutional treatment, attending to the state of the bowels, and giving occasional doses of rhubarb with calomel, or mercury and chalk, and a grain or two of sulphate of quina, twice or thrice a-day, with good diet and fresh air, is by far the most efficacious proceeding; although, whatever may be done, the tonsils, once enlarged, will, under excitement, again and again enlarge, and be very troublesome.—J. F. S.

In connexion with the inflammatory affection of the tonsils, and its occasional results, it may be convenient here to notice the formation of *calculi* in these glands, of which ALLAN BURNS makes the first mention. He says:—"It is not to be inferred that every chronic enlargement of the tonsil depends on thickening and induration of the substance of the gland; it is sometimes produced by the formation of calculi. These seldom in the amygdalæ acquire any considerable size; but their presence is productive of irritation and repeated attacks of cynanche, the inflammation generally proceeding to suppuration. After each successive discharge of matter, a solid and circumscribed tumour remains in the situation of the tonsil, where, sometimes by a probe, the calculus may be detected." (p. 261.) He mentions three cases of this disease, all occurring in members of the same family. In the first there was, during eighteen months, repeated abscess of the tonsil, which burst always externally; a regular and solid tumour was then noticed on the left side, which protruded the skin just below the angle of the jaw, and was followed by a severe attack of inflammation, which ended in suppuration, and bursting externally by eight small apertures, discharged matter during a full year. She then applied to a surgeon, who, having probed the wounds, found a calculus in the gland, and attempted its removal by an external incision, but was deterred

(*a*) MS. Lectures on Surgery.

(*b*) Above quoted.

(*c*) On the Cure of Stammering, by the removal of the Uvula and Tonsils; in the Lancet for 1840–41, vol. ii. p. 587.

by the bleeding from completing the operation, and brought away only a small fragment. "In the course of fourteen days the calculus dropped from the tonsil into the mouth," and the patient did well. In the other two cases the calculus also escaped from the tonsil into the mouth. BURNS says that "these and, indeed, all tonsillitic concretions have been distinguished by a fetid stercoraceous odour. Sometimes the concretion does not acquire the same degree of solidity as in the cases mentioned. In some patients it forms in the cryptæ of the tonsil, enlarging them, and even projecting into the fauces. Where it assumes that form, it can, by any blunt instrument, be turned out from the recesses of the tonsil in gritty masses of a dirty-white colour. The formation of this gritty matter would seem to be connected with some deranged state of the intestinal canal. It will be necessary to pick the foreign substance from the tonsil, and, to prevent its reproduction, the bowels must be restored to their natural action. It is by no means an uncommon affection." (pp. 263–5.)]

133. If the swelling of the hardened tonsils be so great that breathing and swallowing become very difficult, their partial extirpation is necessary. If the swelling be not very great, two or three transverse, but not very deep, incisions are sufficient to produce their diminution in the course of a few days. The removal is best effected by a narrow, slightly curved, blunt-pointed or button-ended bistoury, or with a narrow, straight, button-ended scalpel. The patient should be placed on a seat opposite the light, his head resting on the bosom of one assistant and a little inclined forwards, and his mouth kept open by a piece of cork placed between the hind molar teeth; whilst another assistant keeps down the tongue with a spatula. The operator fixes a double hook, or MUSEUX's hook forceps, which are preferable, in the swollen tonsil, holds the forceps with one hand and manages the knife with the other, so as to divide as much as is necessary of the tonsil at one stroke from beneath upwards. (The hook or forceps are to be used with the left, and the knife with the right, hand, if the left tonsil is to be removed; but the contrary, if the right.) If the tonsil still remain partially attached, it must be cut off by a second stroke of the knife or with COOPER's scissors.

In unsteady patients DESSAULT's *kiotome* is often preferable, which, when the patient is seated as above, the mouth open, and the hook, fixed in the tonsil, is so introduced with its edge retracted, that the tonsil comes against the slit part of the sheath, and the projecting part is cut off by the protrusion of the knife. The introduction of the hook often produces severe tickling in the throat, suffocation, and so on, in order to avoid which the division may be made without previous introduction of the hook. If, on account of its size, the whole tonsil cannot be received into the curve of the kiotome, a part of it must be removed by two oblique cuts meeting at an angle; or cross cuts are to be made with the kiotome, first at the upper part, and next at the lower third of the tonsil; the isolated part is then to be taken into the curve of the instrument, and the two transverse connected by a third longitudinal incision. The deep cleft thus formed falls together in the course of five or six days (*a*). FAHNESTOCK's *tonsillitome* (*b*), with the alterations of VELPEAU and RICORD, is preferable to DESSAULT's kiotome. This instrument closed, that is, with the annular blades covering each other, and with the piercer retracted, is placed over the tonsil, which, projecting through the opening, is to be thrust through with the piercer; the movable stem is then pushed forward upon the immovable one, and the latter, at the same time, drawn back, so that the tonsil is taken off by the rings, of which the inner margins have each a cutting edge. Tying the tonsils is not to be preferred'

(*a*) ITARD, Traité des Maladies de l'Oreille et de l'Audition, Paris, 1821, vol. ii. p. 174.

(*b*) FRORIEP's Chirurg. Kupfertafeln, pl. 447.

to their removal by the knife; but their destruction by caustic is to be rejected. Only in not very great swelling of the tonsils, can their diminution be effected by the repeated application of lunar caustic sufficiently to produce a superficial slough.

The removal of the hardened tonsils has been performed from the earliest time by *cutting*, by *tearing out*, by *tying*, and by *destroying with caustic*. Celsus advised taking hold of the tonsil with a hook and cutting off the hardened part with a knife. In this manner the operation has been performed with little variation. According to Louis, the cut should be made from below upwards; according to Richter, from above downwards, and the imperfectly divided piece is to be removed with scissors; according to Moscati, the cuts are to be made in various ways, by splitting the tonsil from above downwards and sideways, by introducing charpie, by removing it piece-meal, and by cauterizing the surface of the wound with nitrate of silver.

For holding the tonsil, a single or double hook is employed, Caque's hook (*a*), Muzeux's hook forceps (*b*), Wasserfuhr's forceps with thick blunt hooks, so that it may be more easily removed in case of vomiting. For the cutting, a narrow, button-ended, curved or straight scalpel, special knives of Paulus Æginetа, of Caque, of Ben. Bell, of Boyer, Dessault's kiotome; the scissors of Solingen, Percy, Levret; the instrument of Rivieri (*c*) and of J. Cloquet (*d*), with two branches, which cross, and each of which has an edge at its extremity.

Tearing out the tonsils was performed by Celsus with the fingers; by Fabricius ab Aquapendente with the hook or forceps.

Tying the tonsils, mentioned so early as by Guillemeau (*e*), was performed by Sharp (*f*) with silver wire or catgut; by Cheselden (*g*) the loop was applied with the finger and fastened with an eyed probe; swellings with a broader base were tied on the side with a double thread introduced by a needle having an eye near the point; by Bibrach (*h*) with a silver wire by means of Levret's double cylinder; by Siebold (*i*) with a loop pushed on upon a pair of forceps, the ligature having been slipped on to them by an assistant; Bell introduced through the nose a loop which by means of the finger was carried over the tonsil and tied with a polypus-cylinder introduced through the nose; by Chevalier (*k*), a double thread was drawn through the base of the tonsil, after Cheselden's method and tied with a ring-shaped knot closer. Hard also invented a tying instrument (*l*) for the same purpose.

Cauterization of the tonsil with red hot iron or with caustic, after the manner of Severinus and Wieseman.

[Else objected to the excision of the tonsils, especially in children, on account of the troublesome and dangerous hæmorrhage; neither was he favourable to tearing them away with the forceps, nor to destroying them with caustic, but preferred Cheselden's apparatus, consisting of a tonsil probe, needle, iron, and *speculum oris*, or a piece of cork. If the base of the swelling be narrow, a thread can be readily carried round with the probe; but if it be broad, it will be requisite to thrust the needle, armed with a double thread, one white and the other black to prevent confusion, through the base from without inwards, and, when the eye of the needle appears behind the tonsil, the threads are to be taken hold of, the needle withdrawn, and the corresponding threads tied.

The instrument for amputating the tonsils, invented by Physick of Philadelphia (*m*), consists of an oval iron loop, of two plates, rather larger than the ordinary size of the tonsils, and attached to a long stem, upon which rests a sliding rod, terminating in a knife of hexagonal form. The tonsil is received within the ring, and the knife being then thrust forward, cuts it off as it traverses the loop. He also uses a pair of forceps, with lunated extremities, and their opposing faces toothed, to draw the tonsil more firmly through the loop. I do not know whether this is Physick's guillotine instrument, which has been further improved by Mitchell, as I have not seen either. Within the last eighteen months, Simpson, instrument maker, of Westminster, has adapted Thorbern's staphylotome (which he has much simplified) to amputation of the tonsil, by giving the sliding knife an oblique cutting edge, like the guillotine knife, and the tonsil, being drawn

through the aperture with a double hook, is readily cut off. Each side of the throat requires its own instrument, on account of the obliquity of the knife-edge.

In the United States some surgeons prefer scissors to the knife, and others the guillotine instrument of **Physick**, with or without modification. The best scissors are those of Dr. **Smith** of Baltimore, the blades of which are curved on the flat, and bent like a hawk-bill towards each other, so that the points cross when the instrument is shut. Two small steel points are, in addition, attached to the side of each blade, so as to catch the portion excised, and prevent its falling into the glottis (*a*).

Gibson of Philadelphia (*b*), with the view of getting rid of the numerous instruments formerly used for the removal of enlarged tonsil, has invented an instrument which at once keeps down the tongue, holds the gland firmly, and separates it nearly at the same moment. "It consists of a pair of forceps nine inches long, the eighth of an inch thick, half an inch broad when shut, with extremities an inch and a-half long, slightly serrated and somewhat curved, including, when closed, an oval space a quarter of an inch wide, and terminating, at the other extremity, in handles which stand off obliquely from the shafts of the instrument. A knife or blade, the length and breadth of the forceps, rounded on its cutting edge, and having a button placed perpendicularly to its axis on the opposite extremity, works backwards and forwards, by means of a groove, to the extent of an inch and upwards, between the blades of the forceps, to one of which it is secured by screws. A sheath upon each end of the forceps, to keep the knife from starting off the moment it touches the tumour, completes the instrument." (p. 27.) "It is to be passed into the mouth with the blades closed, and resting flat on the tongue, which it presses. The instrument is turned edgewise, still resting on the tongue, its blades expanded, placed fairly around and completely behind the tumour, which is then seized and firmly held, while the thumb, resting on the button-like extremity of the knife, pushes it forwards, and instantly separates the enlarged tonsil, which is immediately brought away in the grasp of the forceps." (p. 27.)

The ordinary practice now is to remove the tonsil by cutting through with a knife, of which the blade is guarded to within an inch of its tip, the gland being drawn inwards towards the mesial line with a tenaculum or double hook. There is soreness for a few days, but granulations soon form, and the wounded part heals.—J. F. S.]

134. The bleeding after this operation is usually stopped by frequent gargling with cold water and vinegar; or charpie dipped in some astringent wash is applied with dressing-forceps to the bleeding part. In cases of necessity the red hot iron must be applied. During the inflammatory and suppurative periods, soothing and subsequently astringent gargles, with borax and so on, should be applied to the cut surface. If the suppurating surface assumes a luxuriant appearance, stronger astringents, even lunar caustic and the hot iron, must be used.

[Of wound of the carotid artery in removing the tonsil gland, I have not met with, nor heard of, a single instance.

Lawrence writes:—"I have removed enlarged tonsils very frequently, the loss of blood, in the majority of cases, not exceeding a tea-spoonful. It would, I believe, always be so, if the parts are in a perfectly quiet state. I once performed the excision in a gentleman from the country, who was obliged to leave London immediately, where there was a state of active congestion in the fauces; the bleeding was considerable, but not alarming."

But their removal is sometimes attended with very fearful hæmorrhage. My friend **Callaway** informs me, that he has "seen sometimes considerable, and, in one case where he had removed the tonsil by the knife, alarming hæmorrhage in a boy of seven years of age, which required stimuli, &c., to recover him from the fainting which followed." I have to thank my friend **Shaw** for the following

Case—A man aged forty years was deaf in the left ear, and the tonsil on that side being enlarged, it was excised with the guillotine on *Saturday*. No bleeding of consequence followed, the gland being hard and light-coloured, as if of old standing. On *Monday* he complained of sore throat, and the incised surface appeared as if a superficial slough were about to form. On the afternoon of *Tuesday* bleeding commenced in the lower part of the cut surface where ulceration had taken place adjoining the slough. An oozing of blood, varying in quantity, continued, in spite of repeated attempts to check it with styptics, till the afternoon of *Thursday*, when he was so much exhausted that the

---

(*a*) See **Pancoast's** Treatise of Operative Surgery. (*b*) Institutes and Practice of Surgery, vol. ii.

carotid artery was tied. The bleeding now ceased completely; the wound rapidly closed, and the ligature came away on the twelfth day; in a short time after which he was discharged cured.

This case seems to bear a close resemblance to that of LAWRENCE'S; and both may, perhaps, be explained, on the presumption that the small vessels of the enlarged tonsil gland were unable either to contract or retract, in consequence of the adhesive matter with which the cellular tissue of the gland was filled, and by which its enlargement was caused, preventing their closure.—J. F. S.]

135. The *Uvula* is frequently so relaxed and lengthened by long-continued and repeated inflammation, that great inclination to cough and vomit, and difficulty in swallowing, is produced. In less degrees of swelling strongly astringent gargles of decoction of oak bark with alum, tincture of catechu, touching with acid, stimulating substances, with lunar caustic (1) and so on, are serviceable. In greater swelling, if these means fail, the removal of the *uvula* is called for. The patient being placed in the same position as for the removal of the tonsils, the *uvula* is to be taken hold of with a pointed hook, and the superfluous part cut off with scissors or with the kiotome. The after-treatment is similar to that for removal of the tonsils.

(1) BENNATI (*a*) recommends cauterization with nitrate of silver by means of a double caustic-holder.

The simple operation of removing the uvula was performed before the time of HIPPOCRATES by cutting, and in this way it has been mentioned by CELSUS, GALEN, ORIBASIUS, AETIUS, and PAULUS ÆGINETA, by means of the already-mentioned various instruments used for removal of the tonsils, to which must be added the *staphylagra* of PAULUS ÆGINETA, to hold, and the *staphylotome* to cut with; THORBERN'S (of Norway) instrument (*b*), with the alterations by RAU (*c*), by BASS (*d*), by FRITZE (*e*). The cauterization first mentioned by DEMOSTHENES of Massilia was performed by PAULUS ÆGINETA with the aid of a *staphylokauston,* and, by the Arabians, partly by caustic and partly by red hot iron; PARÉ used the ligature and the two FABRICII employed, by turns, scissors, caustic and ligature.

[Relaxation and elongation of the uvula is a most troublesome complaint. ASTLEY COOPER, who never removed more of the uvula than would reduce it to its proper proportions, as, if the whole were cut-off, fluids could not be taken without their passing into the nostrils, and without interference with articulation being produced, did not, however, consider any benefit was derivable from the operation, as the uvula almost invariably again acquired its natural length. Neither can I advise it, because from personal experience I know it to be unnecessary. It is commonly sympathetic with irritation of the alimentary canal, and when that is quieted, the uvula resumes its ordinary length. It often becomes very red, lengthens and swells in the course of an hour, and, by its constantly dropping on the epiglottis, irritates it, and excites a constant hacking cough, and frequently a sense of choking; the best immediate remedy for which is closing the mouth, and breathing through the nostrils. I have tried all sorts of astringent gargles, but found little relief from them; and have only been benefited by painting with a strong solution of nitrate of silver twice or thrice a-day, according to the irritation produced.—J. F. S.]

136. *Inflammation of the Parotid Gland* (*Inflammatio parotidis*) has a different course, according as it is connected with catarrhal fever, or is a *symptomatic*, *critical*, or *idiopathic disease.*

137. The *Mumps*, in Scotland the *Branks*, (*Angina* seu *Cynanche parotidea*, Lat.; *Bauernwetzel*, Germ.; *Oreillons*, ou *Ourles*, Fr.,) consists in a sometimes cold and rather œdematous, at other times hot, tense, painful flat or raised swelling of the parotid and submaxillary glands, with which also the tonsils are sometimes swollen, and swallowing and opening of the mouth prevented. The skin generally preserves its natural colour, or has an inflammatory blush. The swelling is frequently unaccompanied with fever, soon disperses, and does not easily run into suppuration; catarrhal symptoms, chilliness, rigors, and depression commonly precede, and it is mostly connected with fever similar to catarrhal, and frequently with active fever. In these cases a metastasis of the fever easily occurs. As the swelling of the parotid gland subsides, a fresh attack of fever with severe shivering, with pain in the loins and pubes, takes place, followed by inflammatory swelling of the testicle, and, in women, of the labia and breasts. Itching and burning in the generative organs, and frequently untimely menstruation, follow. The swelling of the parotid gland often still continues; but sometimes the inflammation, though it may have subsided, returns to the gland. Other parts are also frequently attacked; drowsiness, severe headache, wanderings, inflammatory or spasmodic affections of the breast, active vomiting, dropsical swelling of the whole body with short breathing and high fever occur.

In trifling cases the inflammation often subsides in a few days, sometimes later, with perspiration spreading over the whole tumour or over the whole surface of the body, with critical flow of urine and bleeding from the nose. The passage of this inflammation into suppuration or hardening is very rare. In some cases wasting of the testicle has been observed.

[Dr. Mason Good (*a*) speaks of two kinds of inflammation of the parotid gland; the one just mentioned, and another, which he calls *Parotid Phlegmon,* but both exhibiting two species or varieties, a simple or benignant, and a malignant form.

The first kind, his parotid phlegmon, Good briefly characterizes as "a tumour situated under the ear, reddish, hard; pain obtuse, suppuration slow and difficult," (p. 326,) and is "troublesome, and sometimes fatal." (p. 408.) Of its *benignant* variety he says:—"Though the suppurative process is slow and inactive, the incarnation subsequent upon the breaking of the abscess is regular and unobstructed." He mentions a case of this kind, in which a girl of fifteen years had, after the duration of the disease for ten weeks, "for about a fortnight an evident pointing towards the surface, and a feel of irregular fluctuation; it afterwards broke, a large quantity of good pus drained away daily, and the tumour, which at first was extensive and hard, by degrees very considerably diminished, and clustered or divided into lobes, and at length disappeared altogether." * * * "The abscess, in some cases of this variety, is of considerable magnitude, and consequently the discharge of pus very large." He says, that, sometimes, "the pus has been absorbed, and carried off by metastasis to some remote organ," of which he cites examples. (pp. 327, 8.) The *malignant* variety, Good says, "seldom appears in early life, and, in females, seems sometimes to follow upon the cessation of the catamenia. It is still slower in its progress than the preceding; and, when at length it breaks, the pus is

---

(*a*) Above quoted.

imperfect, and cheesy or scrous. It is also profuse, and protracted to a long period, and accompanied with fatal sloughs. The patient is debilitated by the discharge, the irritation excites hectic fever, and the case frequently terminates fatally." (p. 328.)

The second kind, or *Mumps*, of which Chelius has just treated, Good observes, "is altogether of a different kind" from his first kind; "is more extensive, more painful, and rarely tends to suppuration." This kind, he proceeds to say, "in advanced life, is sometimes apt to run into a chronic form, accompanied with very mischievous symptoms; in which state it is denominated a malignant parotid. This is more especially apt to take place in females, when menstruation is on the point of ceasing, and the general action of the system labours under some disturbance." (p. 409.)]

138. This disease prevails mostly as an epidemic, more frequently in southern than in northern regions, in very changeable, especially moist and wet weather, and in spring time. Some consider it contagious; it, however, attacks only once during life; it seizes on all ages and both sexes, young people especially, and particularly young males. The severity of this disease differs materially in different epidemics.

139. Inflammation of the parotid glands not unfrequently occurs in typhus fever, sometimes with, sometimes without, benefit. Scrofula, syphilis, repulsed eruptions, often giving origin to it, or it is caused by improper use of mercury, carious teeth, difficult dentition, by cold, or by external injury. The character and course of the inflammation differs in these cases. It may be so severe as to run into mortification, but generally has a milder result, and passes into *suppuration* (1), *hardening* (2), and *sarcomatous hardening* of the parotid.

[(1) Evanson and Maunsell (*a*) say, that the swelling of mumps "at times, but very rarely, will proceed to suppuration, and may cause immediate death, by discharging its contents into the larynx, if it burst internally, or lead to great deformity when it opens externally." (p. 216.)]

(2) Mason Good says, his parotid phlegmon "assumes, occasionally, a scirrhous hardness, and grows to a considerable extent; it has been extirpated, but with variable success, when upwards of three pounds in weight (*b*); sometimes with a cure (*c*); but, at other times, it has degenerated into a foul bleeding and extensive ulcer" (*d*). (p. 328.)

140. If the inflammation be mild, the preservation of warmth in the swelling by covering it with flannel, or bags of elder flower and so on, and the use of gentle diaphoretics, are sufficient. If the condition be decidedly inflammatory and the fever severe, antiphlogistic means, and even bloodletting must be employed; moderately, however, and with great caution. But, if the patient be very weakly, and the fever incline rather to the nervous type, mild infusions of balm, valerian, with solution of acetate of ammonia, camphor, and so on, must be given. When the swelling has not properly risen, when it has subsided, or when the perspiration upon it ceases, a blister may be applied. When the inflammation attacks the generative organs they must be kept warm, covered with flannel, and the testicles supported by a suspensory bandage. If the brain be attacked, blisters must be laid upon the scrotum and on the parotid glands and *liquor ammon. acet.* with warm drinks administered internally, and, in depressed vital powers, camphor, antimonial wine and the like. The vomiting originating in nervous irritation must be treated by suitable remedies both external and internal. If the swelling continue long and do not disperse, a volatile liniment with camphor is to be rubbed in.

141. If the inflammation of the parotid gland be connected with dyscratic

(*c*) Siebold, Parotidis scirrhosæ feliciter extirpatæ Historia. Erf., 1791.

(*d*) Commerc. Lit. Nor., 1733–8.

state of the body, a corresponding general treatment must be had recourse to; according to the variety of the symptoms, leeches, mercurial friction, dispersing plasters, herb bags, and derivative remedies are to be used locally.

If the inflammation be critical, every thing must be withheld which may produce its revulsion. If the swelling be accompanied with a proper degree of inflammation, it must be simply covered with a mild poultice; if the living activity in it be too low, stimulating poultices and plasters must be applied.

142. When suppuration has taken place the abscess either breaks of itself under the use of the remedies mentioned in the treatment of abscesses, in which case the cure commonly soon follows; or the formation of abscesses is accompanied with severe symptoms, delirium, lock-jaw, and so on, under which circumstances the swelling is to be soon and sufficiently opened, so that the tension of the aponeurotic sheath of the gland may be relieved. According to its condition, the abscess must be treated with soothing or stimulating remedies. The treatment is always tedious; knotty scars and detached hardnesses readily form. If a fistulous aperture remain, through which the spittle flows, it must be treated by touching with lunar caustic, which, aided by proper compression, will close it (*a*). If the gland become hard, it must be treated after the ordinary rules.

Jeanselme, G., Mémoire sur les Inflammations et les Abcès du Sein chez la Femme; in Gazette Médicale. January, 1839.

143. *Inflammation of the Breast* (*Inflammatio Mammarum*) occurs in women either nursing or after that period; and is situated either in the *skin and cellular tissue* alone, or *in the parenchyma of the gland itself.*

144. If the inflammation occur during suckling, the breast on a sudden becomes tense, red, and swollen. If the inflammation be *superficial*, a regular smooth and shining swelling may be felt, but the secretion of milk does not always cease. In inflammation of the *parenchyma of the gland* the swelling is harder, different knobby swellings are felt, and the secretion of milk is completely stopped. It is not unfrequently accompanied with febrile symptoms.

145. The superficial inflammation of the breast generally subsides of itself; but, if the parenchyma be attacked, the inflammation at a certain stage proceeds to suppuration, and not unfrequently hardening remains.

146. The usual causes of this inflammation are cold, mental excitement,

---

(*a*) For the further consideration of the treatment of fistulous opening in the parotid duct, see Salivary Fistula, *par.* 902.

mechanical injury and so on. Women who do not suckle, or who wean their children early, are specially subject to inflammation of the breast. In order to prevent it, they must use a strict diet, encourage perspiration, take purgatives; apply cotton fumigated with sugar to the breasts, rub the nipples often with spittle, and support the breasts.

[Too many women, to their great shame, refuse suckling their children, on account of the restraint which this, one of their most important duties, puts upon them; some, unfortunately, early loose the progeny they would sacrifice themselves to bring up; and others, either from ill-health or from soreness of the nipples, are incapable of giving suck. In all these cases the secretion of milk must be checked, and the milk already secreted induced to absorb. Spare diet and purging, as recommended by **Chelius**, will usually effect the first object. As to the second, an evaporating lotion of spirit of wine or Cologne water, kept constantly on the breasts, which are to be carefully supported, and, therefore, the recumbent position and undress are the best for the purpose. The ordinary practice of monthly nurses is continued and gentle friction of the breasts with oil and brandy performed three or four times a-day.—J. F. S.]

147. The same remedies must also be employed at the commencement of inflammation. And not until it becomes more active, and the swelling tense and hard, must warm softening poultices and soothing steam be applied to the breast, and emollient ointment rubbed in. If the inflammation disperse, the tension and swelling gradually subside; isolated hardenings slowly disappear under the use of softening poultices and mercurial salve. If the inflammation take place whilst the child is still suckling, it may be freely put to the breast, so long as the swelling and pain are not great. If with a free flow of milk the child cannot draw off sufficient, it must be withdrawn by a milk-glass in the intervals. If the inflammation become very severe, all attempts to remove the milk from the breast are injurious.

148. If the inflammation pass into suppuration, the softening poultices must be continued, cicuta or mercurial plaster applied, and the opening of the abscess left to nature. In general many openings take place at different parts, and they are to be treated in the usual way till they close.

If during suppuration fistulous openings are formed and the breast remain very hard, (which is commonly the case when the abscess is opened artificially, or lumps of charpie are introduced into the openings,) the before-mentioned mode of treatment can alone effect the resolution of the hardening and the closure of the openings.

After much experience, I cannot but reject the opening of abscesses of the breast recommended by many. There are, however, exceptions; when the abscess is very deep, when it has proceeded slowly, when the local pain is very great and the fever high, and profuse perspiration and continued restlessness are present. After the artificial opening, poultices must be always applied as above mentioned. In lengthy fistulous passages in the breast gland, **Langenbeck** recommends the introduction of ligatures. I have, in such cases, even when the fistulous passages have been accompanied with much surrounding hardness, always attained my purpose with the treatment above stated. If milk escape from these passages, its secretion must be lessened by the use of purgative remedies, together with a sparing diet; or, in weakly constitutions, by the use of bark and strengthening food. Nothing is more objectionable than the introduction of tents into fistulous passages of the breast gland, or, as has been very recently, advised, the putting in little tubes to keep up the flow of pus. The irritation is always thereby much increased and hardening of the whole neighbourhood originated.

[**Chelius**'s recommendation of leaving "the opening of the abscess to nature" must on no account be followed, as its certain result is, according to his own observation, the occurrence of "many openings at different parts" of the breast, and the necessary production of very unsightly scars, which most grievously annoy the patient and her friends, and deservedly discredit the reputation of the medical attendant. The abscess is *always to be punctured freely, so soon as fluctuation can be distinctly felt,* and whilst the walls of the abscess are still thick. The almost immediate ease gained by relieving the tension of the fibrous covering of the breast gland is the first advantage obtained; the burrowing of pus is also prevented, and thereby a smaller cavity left, when emptied, to fall together and fill up by granulation; and, most important of all, the sloughing of the skin almost to a certainty precluded. No squeezing or kneading of the breast to evacuate the pus, as often most improperly practised, is to be on any account resorted to, the agony thereby produced is extreme, the benefit gained nothing, for the aperture made should be sufficiently large to permit the free escape of the matter, which, having been allowed to flow as long as it will, a strip of lint, oiled, is to be introduced between the lips of the wound to prevent their union, and a light bread poultice, or warm fomenting flannels laid over the breast and repeatedly renewed. In the course of a few hours the lint should be withdrawn, and the wound generally remains sufficiently open to permit the continual flow of the pus. If, as not unfrequently happens, clots of adhesive matter, or dead cellular tissue, block up the opening so that the matter does not readily escape, they may be gently removed if they protrude between the lips of the wound. But, if not, and the pus be still retained, a grooved director should be very gently introduced into the cavity of the abscess, and by its canal the discharge will pass; but no pressure is on any account to be used. If a second, or even a third, abscess point, or if the same abscess point at a different part of the breast, these are severally to be opened as they occur, the prime object of the treatment being to remove every chance of sloughing and scar of the skin. Oftentimes the first discharge is extremely fetid, more particularly if the opening of the abscess have been delayed, or if it have been left to burst spontaneously, and in these cases the constitutional excitement is frequently very great, amounting even to delirium. The character of the suppuration, however, usually soon becomes healthy, and the febrile symptoms speedily subside. CHELIUS's objections to passing tents or tubes into the fistulous passages, which generally alone occur from leaving the abscess to burst of itself, are well founded; they never ought to be employed. Neither should LANGENBECK's plan of introducing ligatures be for a moment thought of; it is very bad practice.

Fistulous passages almost invariably occur from the pus not having a convenient and complete discharge. Sometimes gentle, well-applied pressure along the course of the sinuous passage may be sufficient to produce inflammation and adhesion of its walls; but, if not, or if the patient cannot, as sometimes happens, bear the necessary pressure, then a probe should be introduced, and its extremity cut down upon through the skin at that part of the sinus which is most depending. Usually in a few days the old aperture heals, the pus is discharged by the new wound, and soon a cure is effected. As a general rule, injections of these adventitious canals is not advisable; but, when the opening is at the most depending part, and they can be employed simply to wash out the canal and slightly irritate it, but without being retained, which will often create more inconvience than that to be got rid of, then they may be used with discretion. A mild solution of sulphate of zinc is, I believe, the best injection.—J. F. S.]

149. After previous inflammation there frequently remain the so-called *Milk-knots*, (*Milchknoten*, Germ., *Ganglions laiteux*, Fr.); or they appear at a shorter or longer period after the suppression of the secretion of the milk, or after weaning the child, in cases where the secretion of milk seemed to have entirely ceased. Their hardness varies, and is often cartilaginoid, though only containing milk; they may remain for a long while, and on superficial examination are easily mistaken for scirrhus. Their termination is in *resolution*, which is still possible after a long while, or in *suppuration* if they accidentally inflame. The remedies which effect their dispersion are, gentle rubbing of the breast towards the nipple, sucking the nipple, softening poultices, especially oatmeal, linseed meal, cicuta, hyoscyamus, saffron and oil, rubbing in lard and hartshorn. Some recommend belladonna internally. The dispersion is always accompanied with a flow of milk from the breast. Milk-knots which have not yielded to any remedies often subside at the next lying-in.

150. Inflammation of the breast, apart from suckling-time, has generally an insidious course. The pain in the neighbourhood is very slight; but the swelling of the breast is always very hard, and the inflammation has a marked disposition to hardening. Its causes are external injury, dyscracy,

scrofula, gout, syphilis, and so on. In many cases the inflammation sets in without any manifest cause, and the ground of the irritation may be merely the sympathetic relation of the breast to the womb, which discovers itself especially at the period of decrepitude, and in unfruitful women, in whom the functions of the womb have never gone on regularly.

151. The treatment of such inflammation must be guided by the previous mischief. Repeated application of leeches, infriction of mercurial ointment, warm covering of the breast, and internal remedies suited to the general dyscracy, are here required, although they can rarely prevent the production of hardening. When this takes place, it must be treated after the general rules.

152. In rare cases, either during suckling or not, deep-seated abscesses form in the breast gland or between it and the pectoral muscles, the formation of which is connected with a deep-seated pain, at first shifting, burning, tearing, with a considerable colourless swelling of the whole breast, and pain on moving the arm, and it continues for a long time before any external fluctuation can be perceived. The pus frequently makes its way out at several points, and the breast gland is hard and swollen. If these suppurating passages be opened, they present a soft reddish fungus. When fluctuation in such abscesses can be ascertained, they must be opened early. If fistulous passages have formed, they must be laid open throughout their whole length, or, in order to prevent deformity of the breast, and interference with its function, (according to **Langenbeck**, the ligature should be introduced,) softening poultices and rubbing with mercurial ointment should be employed. If a part of the breast be so distended by these passages that, after opening them, it seems to hang as it were by a neck, it should be entirely removed; the cure soon follows. The passage to suppuration may perhaps be prevented by the early employment of diaphoretics, by emetics, by dry warmth, and by the application of derivative blisters in the very neighbourhood of the breast.

Hey, William, Surgical Observations.

Richter's, Medicinische und chirurgische Bemerkungen, vol. i. p. 50.

Langenbeck, Nosologie und Therapie der chirurgischen Krankheiten, vol. ii. p. 264.

[In the description which **Astley Cooper** gives of chronic abscess of the breast, it will be seen that he had not noticed the severe pain to which **Chelius** alludes. "Under chronic inflammation," says **Cooper**, "an abscess is sometimes produced, which, from the length of time it is forming, from the little pain which attends it, from the absence of redness and heat in the part, and from the want of rigors and other constitutional symptoms, prevents the suspicion of the formation of matter, and the swelling is supposed to be a malignant tumour, which requires an operation for its removal." (p. 14.)

I had once the ill luck of operating on such a case, of which the following is the account, and will be found to tally so nearly with the ordinary history and course of scirrhus that I may be held excused.

Case—E. S., aged forty-five years, a married woman, admitted,

July 23, 1835. About twelve months since received a blow on the right breast, and four months after, whilst suckling, received another, but she felt nothing more than a slight shooting, of which she took no heed till after weaning her child four months since. She had not suckled from this breast, as the last child would not take it; but the secretion continued, and the milk flowed out till she ceased to suckle. After weaning, the breast began to swell, and she first noticed the lump, for which she applied leeches and fomentations. These diminished the general swelling, but without dispersing the lump, which, on the contrary, continued increasing, accompanied with smarting pain, and at the time of her admission was about the size of a pigeon's egg, situated just below and to the outer side of the nipple, with the skin slightly adherent, very hard, and the nipple somewhat retracted.

July 31. The tumour was removed, and, on cutting into, was found to contain the cyst of an abscess about the size of a walnut, and containing pus. The surrounding parts were thick and hardened, but there was not any appearance of scirrhus. She did well.—J. F. S.]

153. Imperfections of the nipples, if they be too small, inflame, or are overspread with a pustular eruption, render suckling painful or impossible, and frequently give rise to inflammation of the breast gland. Small and deep-set nipples erect themselves best if during pregnancy a ring of horn or wood be worn, in the aperture of which the nipple may be placed. Inflammation of the nipple at first requires lotions of cold water with a little spirit or red wine. If they crack, Hufeland's ointment (*a*) is the best; but, according to my experience, it ought not to be employed without putting on nipple-shields directly afterwards, for the purpose of preventing the linen sticking. This disease may be often prevented, if, in the latter months of pregnancy, the nipples be frequently washed with red wine or with spirit and water. A pustular eruption drying into a scab often surrounds the nipple to a greater or less extent, and occurs mostly in persons who have formerly been subject to the itch or herpetic eruptions. Particular attention to cleanliness, and frequent rubbing in an ointment of hog's lard and flowers of sulphur, or, if little inflammation accompany it, frequent dabbing with solution of sublimate, is according to my experience always sufficient to prevent this eruption, and never have I been compelled to resort to a general plan of anti-herpetic treatment.

For this cracking of the nipples, accompanied with so much pain, Cooper recommends a solution of borax with a little spirits of wine; Hanney (*b*), touching with lunar caustic and wrapping in zinc ointment; from time to time, before putting the child to the breast, it is to be washed with a saturated solution of borax. Upon the application of the "cosmétique infaillible et prompt contre les gerçures au sein, composé par Liebert," *see* Volz (*c*).

154. *Inflammation of the internal membrane of the Urethra*, vulgarly called *Clap*, (*Gonorrhœa*, *Blennorrhœa*, *Blennorrhagia Urethræ*, *Urethritis*, *Urethralgia*, Lat.; *Tripper*, Germ.; *Chaude-pisse*, Fr.,) is produced by any irritation of the urethra by a foreign body, by gouty, rheumatic, scrofulous acrimony, but most commonly by contagion in coition.

["The disease," says Swediaur (a), "is commonly called a *Clap*, from the old French word *clapiers*, which were public shops kept and inhabited by single prostitutes, and generally confined to a particular part of the town, as we see still to-day in several great towns in Italy."—(*note*, p. 22.) He disapproves of the term gonorrhœa, as conveying an incorrect notion, and proposes the use of *Blennorrhagia*, signifying a flow of mucus. Wallace objects to the employment of either designation, and proposes, in their stead, that of *Venereal* or *Syphilitic Catarrh*, which, however, is merely a trivial alteration of the modern French name, *Catarrhe Urethrale*.]

155. The symptoms and course of gonorrhœa vary considerably. In men, at a shorter or longer period, usually six, eight or ten days after an impure connexion (1), there arises a tickling sensation at the orifice of the urethra, which frequently spreads over the whole glans; the lips of the orifice are generally a little swollen and inflamed (2); and the discharge of urine is painful (3). After some time a discharge takes place, at first more serous, but afterwards thick, puriform and yellowish white. The pain is sometimes slight, sometimes severe, extends towards the root of the penis, which itself swells (4); the orifice of the urethra is much inflamed, excoriated, and its canal narrowed by swelling (5); the stream of urine is lessened, and frequently broken (6). Painful erections occur with bleeding from the urethra (7), and, if the spongy body itself be swollen, *painful curving of the penis* or *chordee*, (*chorda*, Lat.,) on account of its not yielding during the erection (8). The patient often feels a heaviness in the pelvis; the scrotum, testicles, and perinæum become very tender (9); the prostate and inguinal glands, painful and swollen. The surface of the glans itself often inflames, swells, and secretes a puriform discharge (*balanitis*.) The foreskin frequently inflames and becomes so swollen that it cannot be brought backwards over the glans (*phimosis*,) or, if this have been forcibly effected, it remains constricted, behind the glans (*paraphimosis*.) The puriform fluid discharged from the urethra is, in active inflammation, of small quantity, discoloured, greenish, even blackish (10), and is not unfrequently wholly suppressed, (*dry gonorrhœa*,) febrile symptoms, inflammation of the testicles, of the eyes, and swellings of the joints ensue. In very acute gonorrhœa the inflammation may be continued even to the bladder and produce dangerous retention of urine (11).

(a) Practical Observations on Venereal Complaints. Edinburgh, 1788. 8vo.

(1) **Hunter** says, on this point:—"In the gonorrhœa the times of appearance are very different; I have had reason to believe that in some the poison has taken effect in a *few hours*, while in others it has been *six weeks*;" however, "six, eight, ten, or twelve days would appear to be the most common period." (p. 32.) **Astley Cooper** says he has known gonorrhœa to "occur within twenty-four hours after connexion; and sometimes a fortnight, or a longer time will elapse before it appears. I have known an instance in which it was delayed *fourteen* weeks, in consequence, I believe, of the general indisposition of the patient." (p. 189.)

(2) "The first symptom which takes place," says **Astley Cooper**, "is a pouting state of the lips of the urethra, arising from inflammation." (p. 190.)

(3) **Hunter** observes, that "there is often no pain till some time after the appearance of the discharge, and other symptoms; and, in many gonorrhœas, there is hardly any pain at all, even when the discharge is very considerable. * * * There is generally, at this time, a greater fulness in the penis, and, more especially, in the glans, although it is not near so full as when erected, being rather in a state of half erection. Besides this fulness, the glans has a kind of transparency, especially near the beginning of the urethra, where the skin is distended, being smooth and red, resembling a ripe cherry: this is owing to the reticular membrane being loaded with a quantity of extravasated serum, and the vessels being filled with blood." (p. 46.)

Travers (*a*) says, that "heat in urining, titillation, tumefaction, which often precede the appearance of the discharge, even for days, may sometimes be removed by rest, purging, and mucilaginous drinks, so that the inflammation is subdued before it reaches purulent secretion. Coition in this state infallibly produces discharge; sometimes with a full, thick, high-coloured discharge, there is neither heat, swelling, nor colour of the *labia urethræ*. These symptoms, on the other hand, may be all considerable, with a thin and scanty discharge, and often without any heat. These differences are only to be explained by reference to the condition and susceptibility, local or general, of the person infected." (p. 7.)

(4) According to **Hunter**, "When the disease attacks the urethra, it seldom extends further than an inch and a-half, or two inches at most, within the orifice, which distance appears to be truly specific, and what I have called the *specific extent of the inflammation*. * * * When the gonorrhœa (exclusive of the affections arising from sympathy) is not more violent than I have described, it may be called *common* or *simple venereal gonorrhœa*; but, if the patient is very susceptible of such irritation, or of any other mode of action which may accompany the venereal, then the symptoms are, in proportion, more violent. In such circumstances, we sometimes find the irritation and inflammation exceed the specific distance, and extend through the whole of the urethra." (pp. 54, 5.)

As to the actual seat of the discharge in the male, **Hunter** says:—"As it would appear that there is hardly a sufficient surface of the urethra inflamed to give the quantity of matter that is often produced, especially when we consider that the inflammation in common goes no further than two or three inches from the external orifice, it is natural to suppose that the discharge is produced from other parts, the office of which is to form mucus for natural purposes, and which are, therefore, more capable of producing a great quantity upon slight irritations, which hardly rise to inflammation. These parts, I have observed, are the glands of the urethra. In many cases, where the glands have not been, after death, so much swelled as to be felt externally, and where I have had the opportunity of examining the urethra of those who have had this complaint upon them, I have always been able to discover that the ducts or lacunæ leading from them, were loaded with matter, and were more visible than in their natural state; I have observed, too, that the formation of the matter is not confined to these glands entirely, for the inner surface of the urethra is commonly in such a state as not to be able to suffer the urine to pass without giving considerable pain; and, therefore, most probably, this internal membrane is also affected in such a manner as to secrete a matter. This discharge, in common cases, would seem not to rise much further back in the urethra than where the pain is felt, although it is commonly believed that it comes from the whole of the canal, and even from **Cowper's** and the prostate glands, not excepting what are called the *vesiculæ seminales*." (pp. 50, 51.)

Astley Cooper asserts, that "the cause of gonorrhœa is undoubtedly inflammation of the *lacunæ* of the urethra, and particularly of the *lacuna magna*. The inflammation is of the erysipelatous kind; but there is no appearance of ulceration. If ulceration were produced, the membrane of the urethra would soon give way. It is merely a secretion from the mouths of the vessels; ulceration does take place in the lacunæ, but not in the urethra itself." [**Cooper** certainly does not here wish it inferred that this ulceration of

---

(*a*) Observations on the Pathology of Venereal Affections. London, 1830. 8vo.

the lacunæ is more than accidental, or that it has anything to do with the gonorrhœa.—J. F. S.] From the opportunity which **Cooper** had of examining a person who had been executed whilst affected with gonorrhœa, he states, that "the inflammation had extended down to the bulb of the urethra; for an inch or an inch and a-half down, the urethra was exceedingly red, and there was some effusion of matter on the internal surface; the urethra was red at the bulb, but not of so deep a colour. The inflammation, therefore, is not confined to an inch or an inch and a half down the urethra, but often extends over the bulb, and in this way produces strictures." (p. 190.)

(5) Not unfrequently small swellings are noticed externally in the neighbourhood of the urethra, which, **Hunter** thinks, are enlargement of its glands; they sometimes suppurate and burst externally, but at other times internally. **Hunter** has well described them:—"At times swelling very considerably, even to the size of a small flattened nut, inflaming, and then a gush of matter flowing from the urethra, they almost immediately subside. The discharge has continued for some time gradually diminishing, till it has entirely gone off, and the tumour been almost wholly reduced; yet, some months after, it has swelled in the same manner again, and terminated in the same way." There can be no doubt of the correctness of his suspicions, that "these tumours are the ducts or lacunæ of the glands of the urethra, distended with their mucus, from the mouth of the duct being closed, in a manner similar to what happens to the duct leading from the lachrymal sac to the nose; and, in consequence of the distension of the ducts or lacunæ, inflammation and suppuration come on, and ulceration takes place, which opens a way into the urethra; but this opening soon closes up, and this occasions a return." (p. 48.)

(6) "The fear the patient is in," says **Hunter**, "when he is making water, assists in diminishing the stream of urine. The stream, as it flows from the urethra, is generally much scattered and broken the moment it leaves the passage, which is owing to the internal canal having become irregular, and *is not peculiar* to a venereal gonorrhœa, but common to every disease of the urethra that alters the exact and natural figure of the canal, even although the irregularity is very far back, as we find in many diseased and prostate glands." (p. 47.)

(7) "The bleeding," **Cooper** (*a*) observes, is "generally from that part of the urethra opposite to the *symphysis pubis*." They are generally serviceable; "but, when they produce fainting, and, as soon as the person recovers from that state the hæmorrhage recurs, and that for two or three times, it must be checked."

"When the inflammation is violent," **Hunter** observes, "it often happens that some vessels of the urethra burst, and a discharge of blood ensues, which is in greater quantity at the close of making water; this, however, takes place at other times, and generally gives temporary ease: sometimes this blood is in small quantity, and only gives the matter a tinge, as I observed when treating of the colour of the discharge. The erections of the penis often stretch the part so much, as to become a cause of extravasation of blood; this extravasation generally increases the soreness at the time of making water, and in such a state of parts, the urethra is usually sore when pressed; yet the bleeding diminishes the inflammation, and often gives ease." (p. 52.)

In rare cases, the *corpus spongiosum* bursts, and a little swelling, caused by the extravasated blood, is observed externally, which, however, is not of material consequence, and is gradually absorbed. But I may here mention, that I once saw a case, under my colleague **Mackmurdo**'s care, in which there was enormous extravasation of blood, from bursting of some vessel in the penis, during the act of coition; and the result of which was, the penis especially and the perinæum were greatly distended, and he was unable to pass his urine without extreme pain, in consequence of which a catheter was introduced. In the course of two or three days, extravasation of urine ensued, and the bladder was punctured through the rectum. Considerable sloughing, not only in the perinæum, but also up into the groins, took place, into which incisions were made, as needed, and he ultimately, though slowly, recovered.—J. F. S.

(8) **Hunter** divides chordee into inflammatory and spasmodic:—"When the inflammation is not confined merely to the surface of the urethra and its glands, but goes deeper, and affects the reticular membrane, it produces in it an extravasation of coagulable lymph, as in the adhesive inflammation, which, uniting the cells together, destroys the power of distension of the *corpus spongiosum urethræ*, and makes it unequal in this respect to the *corpora cavernosa penis*, and therefore a curvature on that side takes place in time of erection, which is called a chordee. * * * As it arises from a greater degree of inflammation than common, it is an effect which may, and often does, remain after all infection is gone, being merely a consequence of the adhesive inflammation. The spasmodic chordee arises from spasm, at least, it cannot proceed from the same cause

---

(*a*) MS. Lectures on Surgery.

with the other, if my idea of that complaint be well founded. The spasmodic chordee comes and goes, but at no stated times; at one time there will be an erection entirely free from it, at another it will be severely felt; and this will often happen at short intervals." (pp. 52, 3.)

ABERNETHY (a) mentions "another, and more permanent, kind of chordee, which arises from inflammation having been propagated to the *corpus spongiosum;* coagulable lymph is thrown out, which glues the cellular tissue together, prevents that part of the *corpus spongiosum* being injected with blood during the erection of the penis, and occasions it to be crooked and bent towards the contracted side. This forms a true and permanent chordee."

HUNTER also speaks of "a soreness often felt by the patient all along the under side of the penis, owing to the inflamed state of the urethra. This soreness often extends as far as the anus, and gives great pain, principally in erection; yet it is different from a chordee, the penis remaining straight. With most gonorrhœas there is a frequency in the erections, arising from the irritation at the time, which often approach to a priapism, especially when there is the above-mentioned soreness, or when there is a chordee." (p. 48.)

(9) HUNTER says he has "seen cases where the irritation has extended so far as to affect with real pain the thighs, the buttocks, and the abdominal muscles; so that the patient has been obliged to lie quiet in a horizontal position; the pain has, at times, been so considerable as to make him cry out, and the parts have been very sore to the touch; they have even swelled, but the swelling has not been of the inflammatory kind; for, though there was a visible fulness, yet the parts were rather soft." (p. 54.)

(10) These changes in colour, HUNTER considers, "depend on the increase or decrease of the inflammation, and not on the poisonous quality of the matter itself; for any irritation on these parts, equal to that produced in a gonorrhœa, will produce the same appearances. * * * It is very probable that there is a small extravasation of red blood in all cases where the matter deviates from the common colour, and to this the different tinges seem to be owing. * * * It has often a smell seemingly peculiar to itself." (p. 56.)

(11) I have seen retention of urine from severe gonorrhœa, in which it was thought necessary to introduce a catheter; a practice, however, which I do not approve of, and I think might be evaded by warm baths, leeching, and purging.—J. F. S.

HUNTER, however, mentions the very contrary condition from the extension of the inflammation. He says, "When the bladder is affected it becomes more susceptible of every kind of irritation, so that very disagreeable symptoms are often produced; it will not allow of the usual distension, and therefore the patient cannot retain his water the ordinary time, and the moment the desire of making water takes place, he is obliged instantly to make it, with violent pain in the bladder, and still more in the glans penis, exactly similar to what happens in a fit of the stone. If the bladder be not allowed to discharge its contents immediately, the pain becomes almost intolerable; and even when the water is evacuated, there remains, for some time, a considerable pain both in the bladder and glans; because the very action of the muscular coat of the bladder becomes a cause of pain by its own contraction. The ureters, and even the kidneys, sometimes sympathize, when the bladder is either very much inflamed, or under a considerable degree of irritation; however, this but rarely happens, and, if it should take place with any degree of violence, I should suppose that the stomach would also become affected, and of course the whole constitution. I have even reason to suspect that the irritation may be communicated to the peritonæum by means of the *vas deferens.* * * * When the inflammation, or perhaps only the irritation, runs along, * * * the disease is generally very violent, and I suspect is something of the erysipelatous kind; at least it shows an irritable sympathizing habit." (pp. 55, 6.)

The constitution scarcely ever is primarily affected on the incursion of gonorrhœa; but HUNTER mentions one very remarkable case of this kind, in which the patient, during six weeks between "the time it was possible for him to have contracted the disease, and its appearance," had, "for a considerable part of that time, often been indisposed with slight rigors, attended with a little fever and restlessness, for which he could assign no cause; nor was he relieved by the usual remedies prescribed in such cases. A violent gonorrhœa came on, and these symptoms went off." In a second attack which the same person suffered, "it was a month from the time of infection before the gonorrhœa appeared, and for some weeks of that time he was subject to a similar indisposition, which went off, as before, when the running came on. Here, it would appear, that we have something of a suppurative fever, which, perhaps, often happens in this disease; but the inflammation being small, and the fever, therefore, inconsiderable, it is commonly but little noticed by the patient." (p. 73.)

(a) MS. Lectures on Surgery.

156. The continuance of these symptoms varies. In slight cases they soon pass by, the discharge gradually diminishes, and (under proper management, commonly in from three to four weeks) completely ceases. Frequently, it becomes chronic, and the discharge (*gleet*) assumes a thin serous ropy character, appears in very small quantity, especially in the morning, after emptying the bladder or after any irritation, and may in this state continue for many months or even years.

["The discharge from gonorrhœa is very much affected by constitutional causes," says **Astley Cooper.** Thus, if with "abundant discharge, considerable pain, and even chordee, the patient should get a fever, the discharge disappears, the pain ceases, and he will be entirely free from all symptoms of the disease for a period of from seventeen to twenty days. As soon, however, as he begins to recover from his fever, the discharge of matter will recur, the pain and chordee return, and a long time may elapse before the disease can be removed." (p. 191.)]

157. The consequences of gonorrhœa by the changes it produces on the mucous membrane of the urethra are thickening, narrowing, stricture, and swelling of the prostate gland.

158. In the female the vagina is the seat of gonorrhœa. The inflammation spreads externally upon the labia, urethra and clitoris. Painful tickling arises in these parts, and soon a copious flow of differently conditioned mucus takes place which produces excoriation, and the gonorrhœa is easily propagated to the rectum (1). The voidance of urine is painful. The symptoms of gonorrhœa are generally less distinct in women than in men; the mucous discharge, however, soon becomes chronic and very obstinate. The detailed symptoms, the manner of its origin, as well as the occurrence of menstruation and the unchanged colour of the face, distinguish female gonorrhœa from the whites (*fluor albus* vel *leucorrhœa*) (2).

[(1) When the urethra had been affected with the disease, **Ricord** states, that "on introducing the finger into the vagina, and pressing the convexity of the urethra, pus was seen to proceed from the interior of the canal, whose surface, as seen through the *meatus urinarius*, appeared swollen." (p. 173; Fr. edit., p. 332.) "The acute urethritis is seldom accompanied by retention of urine, and, when it does exist, it is generally of short duration, and yields to antiphlogistic treatment; but, nevertheless, sometimes it requires the use of the catheter, which ought to be introduced with the parts exposed, notwithstanding the objections raised, as less pain will be caused than if the surgeon have to feel his way." (p. 322; Fr. edit., p. 678.)

In the five cases which **Ricord** describes as utero-vaginal gonorrhœa, and which inoculation proved not to be syphilitic, there was, besides a purulent discharge from the mouth of the womb, upon the *cervix uteri*, "either an ulceration in form of a blister, (p. 161; Fr. edit., p. 310); or several points deeply eroded with a grayish surface, covered with albuminous adhering secretion (p. 162; Fr. edit., p. 313); or a bleeding ulceration (p. 166; Fr. edit., p. 320); or a superficial granulated ulceration, penetrating to the cavity of the *cervix uteri* (p. 172; Fr. edit., p. 332); or erosion at several points, as in some cases of balanitis." (p. 175; Fr. edit., p. 335.)

Hunter says that "sometimes the bladder sympathises, producing the same symptoms as in men, and it is probable that the irritation may be communicated to the kidneys. It has been asserted that the ovaria are sometimes affected in a similar way to the testicles in men; I have never seen a case of this kind, and I should very much doubt of its existence, for we have no instance in other diseases of the ovaria sympathising with those parts or at least producing such symptoms as would enable us to determine they did." (p. 68.) **Ricord**, however, does believe in the occurrence of ovaritis as a complication of gonorrhœa, and speaks of its treatmeant.

Not unfrequently the labia swell under a sharp attack of gonorrhœa, and the nymphæ, together with the *præputium clitoridis*, become infiltrated with serum, and of considerable size, giving to the latter an appearance of being twisted, similar to that sometimes observed in phimosis, or paraphimosis, in the male. Hence **Ricord** compares it to "a kind of phimosis or paraphimosis," and he speaks of it as occasionally terminating in gangrene, which, however, I do not recollect to have observed.

Abscesses in the labia or nymphæ are not of unfrequent occurrence as concomitants with gonorrhœa, and Hunter considers them "as similar to the inflammation and suppurations of the glands of the urethra in men." (p. 68.) RICORD speaks of simple abscesses complicating urethro-genital gonorrhœa; but I cannot clearly make out whether he refers to the labial or nymphal abscesses just mentioned, or to abscess actually in the vagina itself; if the latter, I have never seen the disease. He says:—"These abscesses sometimes depend upon the inflammation of the cysts, which some women have at the entrance of the vulva; in all cases they ought to be promptly opened. It should be noted that suppuration here quickly succeeds to inflammation, and, if the pus be not allowed to escape, infiltration of the loose cellular tissue surrounding the rectum, and, lastly, perforation of this intestine, thus forming either complete or incomplete fistules." (p. 323; Fr. edit., p. 680.)

(2) The distinction between clap and the whites in women is by no means so easy as CHELIUS presumes; indeed, according to Dr. LOCOCK's (*a*) account of the latter, it is scarcely possible to distinguish them, except by the history, which is not always to be relied on. LOCOCK says:—"The discharge of simple leucorrhœa is mucous—merely an increase of the natural moisture of the part; it becomes more abundant than in health, but retains its character of mucus, being clear, transparent, colourless and glutinous to the touch. This rarely goes on to a great extent without being altered in its appearance, and much more watery. In general this sort of discharge is accompanied with but moderate symptoms, is more gradual in its progress, and is unattended with pain; there is little or no inflammatory action present. In other cases the discharge is whitish and opaque, becomes creamy when rubbed between the fingers, and rendering water turbid. This sort of discharge has been considered by Sir CHARLES M. CLARKE andothers to depend on an inflamed condition of the *cervix uteri;* it is rarely abundant, but occasions much disorder of health and local pain. A watery discharge resembling serum is a very common result of more acute inflammatory action in the mucous surface, and, in general, appears suddenly as the effect of cold or any active excitement. It occasionally becomes very abundant, is attended with much local heat and soreness, and soon becomes puriform or mixed with purulent matter, and sometimes with bloody streaks. When it is fetid, brown, or coming away in violent gushes, organic disease of the uterus is to be feared, the nature of which can only be ascertained by an examination *per vaginam.* Purulent discharge from inflammatory action may also take place from the vagina, independent of gonorrhœa from impure connexion; and this may be said to form one variety of leucorrhœa, as, although it may often arise from organic disease of the uterus, it is not unfrequently met with in a perfectly healthy state of that organ." (p. 35.) "In the mildest form of the disease," LOCOCK observes, "the menstruation is either scanty or too profuse:" thus, its presence cannot be considered as distinctive of gonorrhœa, or its absence of leucorrhœa, as presumed by CHELIUS. "The most acute form of leucorrhœa is," proceeds LOCOCK, "most commonly the effect of cold, of metastasis, or of some local irritating cause, and consists of a profuse watery or purulent discharge, accompanied with local pain and soreness; the vagina is hot, very tender to the touch. * * * All these forms may end in chronic leucorrhœa, where the discharge is more or less profuse and constant, mucous, or purulent, or a mixture of both; it may become green and offensive, and yet may be the result only of functional disorder. The quantity poured out is sometimes very abundant, even to the extent of a pint and a half in twenty-four hours; it will then be expelled in gushes in any change of posture." (p. 36.) Unless the symptoms of debility resulting from this state of things be checked, the patient dies exhausted.

In summing up, LOCOCK makes the following excellent and judicious observations:—"It is important to be able to distinguish between gonorrhœa and common leucorrhœa; * * * but it is very doubtful whether any very accurate diagnosis can be formed. It has been stated that in a recent gonorrhœa there is *ardor urinæ* which does not accompany leucorrhœa, unless unusually acrid. But how are we to distinguish in a case of this unusually acrid leucorrhœa, or where a gonorrhœa is not recent? The redness and tumefaction of the labia, nymphæ, &c., can only be seen in a recent gonorrhœa, and they may be seen in severe cases of leucorrhœa, particularly in those following local irritation, or possessing more acute inflammatory action. One other test is mentioned by authors, that in leucorrhœa the discharge ceases during menstruation, but does not in gonorrhœa. This, however, is denied by other authors, and, as Dr. JEWEL observes, "this is a point which cannot easily be decided, as, from the colour of the menstrual secretion, that of the leucorrhœal or gonorrhœal must necessarily be in a great measure obliterated." (pp. 38, 9.)

(*a*) See his article on *Leucorrhœa*; in Cyclopædia of Practical Medicine, vol. iii.

It will be here convenient to notice the *pudendal discharges* which occur very frequently in female children soon after birth, which are generally purulent, and produce redness and swelling of the external generative organs, and not seldom accompanied with excoriation and sloughing of the skin, which may, as I have seen it, more than once or twice, extend to the upper part of the thighs, in consequence of the irritating nature of the discharge. LOCOCK says:—"It is very apt to occur also during dentition, and not only when the first set of teeth are in progress, but at the time of the second set, and even when the *dentes sapientiæ* are irritating the system at a mature age." (p. 39.) I do not recollect to have noticed it at these latter periods, but have no doubt of the correctness of LOCOCK's observation.

A knowledge of this occurrence is highly necessary, and is very properly insisted on, as there is no doubt that many men have suffered capital punishment from the ignorance of practitioners on this point. And, even now, with our better knowledge, it is by no means unfrequent to hear of medical men giving a decided opinion, which is almost certainly erroneous, upon the gonorrhœal character of pudendal discharges, and thus jeoparding the character, if not the life, of an innocent person. On all occasions of giving opinion or evidence in such cases the practitioner is bound to speak with extreme caution, and only upon the most incontestible proof, which, on the mere examination of the parts, it is almost impossible for him to attain, to make a positive statement as to the gonorrhœal character of the discharge.

It is also to be remembered that an epidemic vaginal catarrh has occasionally happened, as mentioned by Dr. PERCIVAL (*a*), at Manchester, in 1791; by Dr. FERRIAR (*b*), in 1789 and 1790; by Dr. MACKINTOSH (*c*), at Edinburgh; by KINDER WOOD (*d*), at Oldham, in 1815; and by CAPURON (*e*).

159. As to the *nature* of gonorrhœa (1) and its connexion with the venereal disease the following distinctions are laid down:—

1. Gonorrhœa *arising without infection*, *from external injury*, for instance, hard riding, blows upon the urethra, onanism, too frequent connexion, introduction of foreign bodies into the urethra and so on; or *from internal disturbance*, as herpetic, or gouty humours, repelled eruptions, suppressed secretions and so on (2).

2. Gonorrhœa *depending on peculiar contagious* matter, the influence of which, however, does not spread beyond the urethra (3).

3. Gonorrhœa *which has a venereal origin*, rather as consequence of general venereal disease, or as a primary syphilitic affection with or without ulceration. This kind of gonorrhœa may pass into general venereal disease (4).

[(1) The only kinds of gonorrhœa which can be admitted are two, the *gonorrhœa benigna* and *gonorrhœa virulenta*, "the terms *benigna* and *virulenta*," as LAWRENCE (*f*) observes, "not indicating the mildness or severity of the symptoms, but denoting the causes which produce those symptoms. *Virulenta* generally means that which is produced by the morbific or poisonous state of gonorrhœa; the other term (*benigna*) indicates any other cause that may excite inflammation of the urethra." (p. 776.)

(2) HUNTER (*g*) even observes, that "sometimes discharges happen spontaneously, when no immediate cause can be assigned; such may be called *simple gonorrhœas*, and have nothing of the venereal infection in them, though those that have been formerly subject to virulent gonorrhœas are most liable to them." (p. 34.) He (*h*) mentions, also, a remarkable case arising from sympathy with the cutting of a tooth. "A boy, about two years of age, was taken with a pain and difficulty in making water, and voided *matter from the urethra*. I suspected, by some means or other, this child might possibly be affected by the venereal poison; and the suspicion naturally fell on the nurse. These complaints sometimes abated, and would go off altogether, and then return again. It was observed, at last, that they returned only upon his cutting a new tooth. This happened

so often, regularly and constantly, that there was no reason to doubt but that it was owing to that cause." (p. 245.)

Everard Home (*a*) says, he has "known a simple gonorrhœa to be brought on by the internal use of arsenic, and to continue for some time after that medicine has been left off, and then disappear. He has also known it to be a consequence of the internal use of ginger." (*note*, p. 35.)

The discharge from the urethra which often arises in men after connexion with their wives, whilst labouring under leucorrhœa either in its mild or acute form, may be placed under this head. It sometimes is very severe. **Hunter** mentions a case of this kind. "The parties have been married these twenty years and upwards; the wife has, for many years past, been at times troubled with the *fluor albus.* When he has connexion with her at such times, it generally, though not always, produces an excoriation of the glans and prepuce, and a considerable discharge from the urethra, attended with a slight pain. These symptoms commonly take a considerable time to go off, whether treated as a gonorrhœa or as a weakness." **Hunter** asks: "Is this a new poison? and does it go no farther because the connexion takes place only between two? What would be the consequence if she were to have connexion with other men, and these with other women? or if he were to be connected with other women? Such cases, as far as I have seen, have only been in form of a gonorrhœa; they have not produced sores in the parts, nor, as far as I know, do they ever produce constitutional diseases." (p. 65.) All the discharges above enumerated must be included under the designation of *gonorrhœa benigna* seu *simplex.*

(3) With regard to the second kind of gonorrhœa, mentioned by **Chelius** as "depending on peculiar contagious matter," it is doubtless the so-called *gonorrhœa virulenta*; but I cannot agree with him that its "influence does not spread beyond the urethra," as, from the observations of other surgeons, as well as from my own, I am convinced that, in certain persons, it does become a constitutional disease, and exhibit distinctive characters, although even **Lawrence** says that "gonorrhœa consists of inflammation of a mucous surface, that of the urethra or vagina going through a certain course, coming to a natural end, and not attended with further effect than those which immediately occur in the parts conceived." (p. 810.)

[The following observation of **Abernethy's**, is too important to pass by as coming from so high an authority, though I do not agree with it. "I am ready to affirm," says he, "that I have of late years seen as little of what was called *Gonorrhœa virulenta* when I was a young surgeon as I have of the syphilitic chancre. The *Gonorrhœa virulenta* was a most active inflammation in the front part of the urethra, the discharge was of very thick pus, having a peculiar and very fetid odour. The disease began by degrees, but soon attained a considerable height, and continued on an average for three weeks; at which time, or shortly afterwards, the inflammatory actions ceased, the discharge became less consistent, and lost its characteristic fetor. The running, however, still continued, and occasionally for a great length of time, rather, as it appeared, in consequence of the disturbance induced, than as an immediate effect of the disease; for I have known instances where the gonorrhœa has ceased without leaving any afterclap or gleet; and many in which this symptom, when it occurred, has been of very short duration." (p. 276.)

(4) It seems now generally admitted that gonorrhœa and syphilis are two decidedly distinct diseases, and therefore **Chelius's** third division, "Gonorrhœa with a venereal origin," will not hold. The question of the identity of the diseases has been long and fiercely disputed in the schools; but the observations and experiments of **Hernandez** and **Ricord** have, to my mind however, put the matter completely at rest.

Of the existence of gonorrhœa, at least as early as the beginning of the 14th century, there seems to me no doubt. **Beckett** (*b*), indeed, says, (quoting from **Stow's** Survey of London,) as early as the year 1162, "divers constitutions relating to the Lordship of Winchester were to be kept for ever according to the customs from time immemorial, among which it is ordered, that 'no stewholder keep any woman that hath the perilous *infirmity of burning.*'" **John of Gatesden**, who practised about the year 1320, and was a fellow of Merton College, Oxford, wrote the *Rosa Anglicana,* in which, among other things, he treats *De Leprâ*, and, in one of the sections on this subject, entitled, "De infectione ex coitu leprosi vel leprose," he says, "Primo notandum ut ille qui timet de *excoriatione et arsura virgæ* post coitum statim lavet virgam cum aqua mixta aceto vel cum urina propria et nihil mali habebit. Secundo, oportet dicere mulieri

---

(*a*) J. **Hunter** on Venereal Disease.

(*b*) An Attempt to prove the Antiquity of the Venereal Disease long before the Discovery of the West Indies, in a letter to Dr. **James Douglas**; in Phil. Transact., 1718, No. 357, p. 839.

supposite ut saltet retro, descendat fortiter per gradus et sternutet cum pulvere piperis vel cum penna in aceto in naribus, ita ut sperma prius receptum descendat, et tunc lavet se in decoctione rosæ et plantaginis decoctarum in vino et furfure, et tunc erit secura." (p. 61) (*a*). JOHN OF ARDEN, who lived through the greater part of this century, and at the age of seventy years, in the year 1377, wrote "propria suâ manu," the MS. No. 75 of the Sloanian Collection, however, speaks, in another MS. No. 2002 of the same collection, of the disease "qui dicitur *Chaude-pisse*;" and BECKETT quotes from another MS. a prescription of his, "contra *Incendium*," which I have not been able to find.

On the other hand, the generality of Surgical writers presume that syphilis had not existed prior to the discovery of America, in 1492, or the siege of Naples, in 1495. I am not, however, by any means sure that even syphilis with its primary sores in shape of chancres, was not known to JOHN OF ARDEN, if not indeed also to JOHN OF GATESDEN, as hereafter I shall endeavour to prove. I have therefore merely referred to the presumed later appearance of syphilis that I may avail myself of the opinions of those who so think; but I believe that disease existed long before. It is not however, in reality, of much consequence, but simply a matter of literary curiosity, because the decision of the question rests not there, but upon the experiments mentioned by BENJ. BELL, and more especially on those performed by HERNANDEZ and RICORD.

"Although," HUNTER says, "it has been supposed by many, that the gonorrhœa and the chancre arise from two distinct poisons; and their opinion seems to have some foundation, when we consider only the different appearances of the two diseases, and the different methods of cure; which, in judging of the nature of many diseases, is too often all we have to go by: yet if we take up this question upon other grounds, and also have recourse to experiments, the result of which we can absolutely depend upon, we shall find this notion to be erroneous." He proceeds to inquire into the introduction of the venereal poison among the inhabitants of the South Sea Islands, combats the opinion that chancre was first introduced into Otaheite, by stating that it was "almost impossible to carry a chancre so long a voyage without its destroying the penis; while we know from experience that gonorrhœa may continue for a great length of time;" and determines, for this reason, and also that "only a gonorrhœa can be cured by simple means," which seem all that the natives adopted, "that the disease they had must have been a gonorrhœa," (p. 14;) and "that every form of the disease has been propagated from one root, which was most probably a gonorrhœa." He then continues:—"If any doubt still remains with respect to the two diseases being of the same nature, it will be removed by considering that the matter produced in both, is of the same kind, and has the same properties; the proofs of which are that the matter of a gonorrhœa will produce either a gonorrhœa, a chancre, or the lues venerea; and the matter of a chancre will also produce either a gonorrhœa, a chancre, or the lues venerea." (p. 16.) To make this circle complete he ought to show that the matter of lues venerea will produce gonorrhœa; but he distinctly states:—"It has never yet been known to produce a gonorrhœa from the constitution." (p. 308.) It must be here observed that HUNTER considers chancre and lues venerea two distinct forms of the disease, the one primarily exhibiting it locally, and the other only through the constitution.

"To account for these two different effects of the same poison," HUNTER observes, "it is only necessary to observe the difference in the mode of action of the parts affected when irritated, let the irritation be what it may. The gonorrhœa always proceeds from a secreting surface, and the chancre is formed on a non-secreting surface. * * * The poison, then, being the same in both cases, why do they not always happen together in the same person? * * * Although it does not often happen so, yet it sometimes does, at least there is great reason to believe so. I have seen cases where a gonorrhœa came on, and in a few days after in some, in others in as many weeks, a chancre has appeared; and I have also seen cases where a chancre came first, and, in the course of its cure, a running and pain in making water have succeeded. It may be supposed that the two diseases arose from the original infection, and only appeared at different times. * * * I suspect," he proceeds, "that the presence of one irritation in these parts, becomes in general, a preventive of the other. I have already observed that the two parts sympathise in their diseases, and it is possible that that very sympathy may prevent the appearance of the real disease; for, if an action has already taken place which is not venereal, it is probable that this sympathy will not cease while the cause exciting it exists; and therefore when both happen in the same person at the same time, I suspect that either the urethra never had sympathised with the chancre, or if it did at first that sympathy had ceased, and then the venereal matter might stimulate the parts to action." (pp. 17, 18.) It is not at all clear what HUNTER means by this sympathy between the

(*a*) Edition of 1492. Pavia.

chancre and the urethra, or its absence; but it is very strange that he should seem to consider the simultaneous existence of gonorrhœa and chancre rare, as it is matter of daily occurrence.—J. F. S.

Benjamin Bell (*a*) denies the identity of gonorrhœa and syphilis. He says:—"The refusal of some patients to submit to the distress and inconveniency, the frequent result of a protracted mercurial course, and who, nevertheless, recovered from the usual symptoms of gonorrhœa, first suggested a doubt of the two diseases being produced by the same contagion. * * * The symptoms and consequences of gonorrhœa are perfectly different from those which take place in lues venerea. Both diseases have appeared, at different periods, in the same countries; and, in some instances, they have remained distinct and uncombined for a great length of time." (pp. 2, 3.) As to the assertion "that gonorrhœa sometimes terminates in pox, and, therefore, that this of itself is a sufficient proof of the two affections being of the same nature," he says, "Were it certain that this ever happened no further evidence would be required, as a few well-marked instances would be conclusive; but every unprejudiced practitioner will admit that no sufficient proofs of it have ever occurred. In order to support this opinion, data must be received which we know to be inadmissible. We must admit, that a person with chancres only communicates to another, not only every symptom of pox but of gonorrhœa, and that another, with gonorrhœa only, gives to all with whom he may have connexion, chancres with their various consequences. This ought, indeed, to be a very common occurrence, insomuch that every practitioner should be able to decide upon it with certainty, if this opinion was well founded. Instead of which, it will be admitted by all, that the one disease being produced by the other is, even in appearance, a very rare occurrence." (pp. 6, 7.) **Bell** subsequently observes:—"As a further proof of the difference of the contagions of syphilis and gonorrhœa it may be remarked, that no stage of pox has ever been known to induce gonorrhœa, which surely would occasionally happen if the two diseases were of the same nature. We may also remark, that, in numberless instances, people have been poxed by the matter of syphilis being by accident applied to a cut or a scratch, as often happens with surgeons in the dressing of chancres and buboes; but no one ever heard of a pox being got in this manner from the matter of gonorrhœa. It has been said that chancres may be produced by insinuating the matter of gonorrhœa beneath the skin. But experiments upon this subject are productive of such anxiety and distress, that they never have been, nor ever probably will be, repeated so frequently, as the nature of it would require." (pp. 32, 3.) He, however, mentions some experiments made by two young gentlemen upon themselves with a view to ascertain the point in dispute. * * * By the introduction of the matter of chancres as well as of buboes into the urethra, some pain and irritation were excited, but *no gonorrhœa ensued*; and, by fretting the skin of the prepuce and glans with a lancet, and rubbing the parts with the matter of gonorrhœa, slight sores were produced, but they never assumed the appearance of chancres, and they healed easily without mercury." (p. 34.)

Bell flatly denies **Hunter**'s assertion, that "at Otaheite every form of the (venereal) disease has been propagated from one root, which, most probably, was a gonorrhœa;" by his statement, "when Captain **Cook** visited these islands, in his second voyage, we have authority for saying that *gonorrhœa* had not then appeared in them." (p. 36.)

Having thus given an abstract of the opinions of **Hunter** and **Bell** as to the dispute on the identity of gonorrhœa with syphilis, it only remains to show that **Bell**'s opinion that, for the reasons above assigned, experiments upon this subject "never probably will be repeated so frequently as the nature of the case requires," can no longer be maintained, as most conclusive experiments have been most ably and numerously made by **Hernandez** and **Ricord**, by which the distinct nature of the two diseases is completely proved.

Hernandez (*b*) had the opportunity of making his observations on galley-slaves, over whom he had perfect control. From these he selected three who had gonorrhœa, to furnish the necessary virus with which he experimented; and he justly observes:—"These experiments, made on seventeen persons, are the most numerous and perhaps the most careful that have been made, and furnish important results. In five of these cases the cure was quick, without internal remedies, and without the ulcers having any venereal appearance. In the others, there were obstinate ulcers, some possessing quite the syphilitic appearance, accompanied with general symptoms which seemed to confirm it. Surely such proofs did not exist in the cases I have mentioned, and yet they were regarded as decisive. Yet all depended upon known internal disorders; all the ulcers yielded to means calculated to destroy these disorders, but which have no virtue in syphilis. * * * My experi-

(*a*) Quoted at the head of this article, vol. i.

(*b*) Essai Analytique sur la Nonidentité des Virus Gonorrhoïque et Syphilitique. Toulon, 1812. Quoted from **Ricord**.

ments prove that the ulcers which are produced, by inoculating the gonorrhœal virus, are not syphilitic, and at the same time point out the source of errors which may render these experiments, which appear so simple and decisive, of little value. They show how circumstances may change the nature of ulcers, or disguise them, and to such degree that it may easily impose on inattentive observers who do not foresee these cases of complication." (pp. 48, 9; Fr. edit., pp. 112–13.)

The assertion that "one woman, having connexion with several men, could give chancres to some, and to others gonorrhœas and buboes, whence the conclusion as to the identity of the nature of these different actions, the principle being always the same in all, and the difference only in the form determined by the locality and degree in which the cause acts," is now completely disproved by Ricord's observations:—"If such reasoning have remained for a length of time without refutation, it cannot," says he, "be now persisted in. Since I have applied the *speculum uteri* to the study of venereal diseases, the hitherto inexplicable enigmas are reduced to the most common and simple facts. With the aid of this instrument I have found that a woman may be affected, at the same time, with gonorrhœa and deep chancres of the vagina or uterus and the gonorrhœa alone show itself externally; apparently affected with gonorrhœa, she could very easily communicate chancres and gonorrhœa together, or only one of them, according to the predisposition of the persons who exposed themselves to the infection. But we can affirm, and from numerous observations, that whenever we have examined women who have communicated disease, we never found that a chancre had been produced by a discharge without ulceration in the sexual organs of the person who had communicated. Inoculation has confirmed what observation of ordinary contagion, better made with the assistance of the *speculum*, had established. In women, gonorrhœa, considered throughout, in the whole extent of the organs of generation, in its different phases of acuteness or duration, and inoculated in the same manner as employed for chancre, produced no result, whenever the mucous membrane was not actually the seat of chancre." (pp. 52, 3; Fr. edit., pp. 118, 19.)

In reference to the opinion that "the cause of chancre and gonorrhœa being the same, the difference in the form depended upon the tissues affected, and that thus the syphilitic virus applied to a non-secreting surface produced a chancre, and the pus of chancre, upon mucous membranes only, produced gonorrhœa," Ricord says, positively:—"We know that gonorrhœal matter never produces chancre on the skin, and that, applied to mucous surfaces, when it acts, it only produces a discharge. The gonorrhœal secretion, applied to the mucous membrane of the eye, has never produced chancres of the conjunctive coat, or of the eyelids, nor, on the other hand, *has the muco-purulent secretion of gonorrhœal ophthalmia ever produced chancres by inoculation or otherwise*, although the eyelids are susceptible of being affected by chancre. We may add that the muco-pus of a balanitis or posthitis, consequent on an impure coition, or produced artificially by an irritant, has never furnished a result by inoculation, and that these affections, therefore, cannot be followed by symptoms of constitutional pox, whenever they have existed without chancres." (p. 58; Fr. edit., pp. 129–31.) In regard to the two "pretty frequent and regular consecutive symptoms of gonorrhœa, buboes, (yet far less frequent than after chancre,) and swelled testicle, I have ascertained, by inoculation, [that the pus from such buboes, the buboes being then in similar condition, does not inoculate, which, in this case, rarely terminate in suppuration, and with engorgements, or simple abscesses, the characters of which frequently correspond to strumous and not syphilitic affections. As to swelled testicle, which still more rarely suppurates, the pus never produced any thing by inoculation." (p. 58; Fr. edit., p. 132.)

The following are the inferences which Ricord draws from his observations on the inoculation of gonorrhœal matter:—

"1. The matter of gonorrhœa, applied to a healthy mucous membrane, causes gonorrhœal inflammation, so much the more easily, the nearer it approaches the purulent form, and therefore, contrary to the opinion of Whateley, the less mucous its nature.

"2. Under no circumstances can it produce chancre; but, as an irritating matter, like that of coryza for instance, it may excoriate the skin, with which it remains some time in contact, but it never produces a specific ulcer.

"3. The consecutive, undoubted, and regular symptoms of gonorrhœa do not furnish an inoculable pus.

"4. The symptoms of constitutional syphilis are not the consequence of gonorrhœa. In all the cases in which authors mention that it was an antecedent, the frequency of which precisely corresponds with that of masked chancres, (*chancres larvés*,) the diagnosis was not correct; the diseased surfaces not having been examined.

"5. Lastly, the only correct means of diagnosis, in the present state of science, is inoculation. Every gonorrhœa which is tested by inoculation in its various periods, without producing any result, is only a simple affection, and incapable of communicating syphilis, whether primary in another subject, or constitutional in the one first affected." (p. 59; Fr. edit., p. 133.)

It is very commonly held by those who consider gonorrhœa and syphilis as distinct diseases, that in the former there is not ulceration, the gonorrhœa being, as described by **Wallace** (a), a "diffused and superficial disease, with increased and altered secretion, but *without loss of substance* or ulceration." (p. 233.) But, as **Ricord** observes, it is well known and proved by pathological anatomy, that, as the speculum shows us every day, gonorrhœa is often accompanied or followed by erosions, or more or less extensive destructions of the mucous membranes; but the ulcerated form of gonorrhœa, if I may thus express myself, does not render it more capable of being inoculated than that which is not; the gonorrhœal ulcers being essentially distinct from chancre." (p. 53; Fr. edit., p. 119.)

The best account of gonorrhœal sores and their consequences is certainly that given by **Travers** (b).

"The distinguishing features of sores produced by gonorrhœal matter are," says **Travers**, "circularity, flatness without induration, whether raised or level, with the surface; seldom solitary, often several; the greater frequency on the anterior and posterior verge of the perpuce, or beside the frænum, *i. e.* at the angles of reflection between the layers of the prepuce, or the close and loose investment of the glans, than elsewhere. In the female, they are likewise commonly situated at the junction of the mucous with the cuticular membrane upon the labia, or at their inferior commissure. Their margin is blunt, but not indurated; the character of the granulation is spongy and indolent, and, though they clean readily, they heal slowly." (p. 13.)

"The proper gonorrhœa, or inflammatory secretion from the sound mucous lining of the urethra, while confined to it," says **Travers**, "is incapable of producing secondary symptoms to the individual; its bubo, if present, is sympathetic, so is the sore throat, or inflamed membrane of the eye or nose, if one or all should follow; *i. e.* they have no character but that of simple and superficial membranous inflammation. As these unquestionably do sometimes follow, though in so slight a degree as to be scarcely noticeable, the circumstance can only be explained by attributing it to the same *consensus partium* which determines the selection of these parts for the specific appearances when the matter of secretion is absorbed, and acts as a morbid poison. But, when the matter of gonorrhœa is absorbed by an excoriated surface, and this surface becomes an ulcer, the matter which it secretes is capable of producing, by its absorption into the system, secondary symptoms in the individual. The absence of secondary symptoms in pure gonorrhœa depends, therefore, not upon any difference in the quality of the matter, but upon a law of the animal economy, *that the inflammatory secretions of the sound surface are not absorbed into the system.*" (pp. 10, 11.)

"The secondary symptoms of the gonorrhœal sore are as strongly marked," continues **Travers**, "present as distinct a character as those of lues. The glands in the groin are oftener large and indurated, than otherwise, in protracted cases; but, as in proper gonorrhœa, the affection is sympathetic. The appearance of secondary symptoms is certainly not peculiar to these cases. The inflammation of the *velum palati* and uvula is diffuse and superficial; the surface is roughened with innumerable small and shallow indentations where ulceration has taken place. They are so slight as often to escape ordinary observation. They are seen chiefly upon the tonsils, uvula, apex, and edges of the tongue. * * * The gonorrhœal sore throat is accompanied by considerable irritability to stimulant fluids especially. The exacerbated ulcer of lues, with its abrupt high-coloured margin, is not more strongly characterized, or more readily distinguished. The cutaneous affections are slight, and, in character, presenting less variety than those of lues, so far as my observation enables me to speak. The papular and squamous are the most common, the pustular and tubercular occasional. The lichen and psoriasis upon the trunk and limbs, and the achor and acne indurata thickly distributed upon the face and the verge of the hairy scalp, are the forms which I have chiefly recognised." (pp. 14, 15.)

With regard to the gonorrhœal sore throat, since it was first pointed out, many years since, by **Travers**, I have continually observed it, I think quite as frequently when there was merely discharge without any sore, as when with it; and so surely does it accompany gonorrhœa that, if perceived in the throat, I invariably inquire if the patient have a clap, and scarcely remember to have found it absent. I think it has a very close resemblance to the non-specific aphthous sores in the mouth and throat indicative of mucous irritation in the bowels, and the sores are generally about the size, or somewhat less, than a silver penny, and are commonly accompanied with fulness of both tonsils and uvula.

(a) Quoted at the head of the article.

(b) Above cited.

I feel also pretty well assured that some eruptive affections of the skin are consequent on gonorrhœa, which are distinguished by their pinky stain from the copper stain of syphilis. But I am doubtful whether I have seen more than acne, lichen, and lepra.—J. F. S.]

160. The *diagnosis* of these several kinds of gonorrhœa is in many cases obscure and not to be determined with certainty by characteristic symptoms; but its mild course, the short continuance of the discharge, the condition of the patient previous to the disease, the perhaps ascertained state of health of the person from whom the contagion has been received, in most cases furnish the guide. All gonorrhœa which has a malignant course, in which swelling of the testicles, inflammation of the inguinal and of the prostate glands occur, may be considered as syphilitic. In syphilitic gonorrhœa of women the danger of general syphilis is always greater than in men, on account of the copious secretion of mucus, and the excoriations thereby produced.

[Almost all that can be said on the diagnosis of vaginal discharges has been already mentioned, in speaking of gonorrhœa in women, and leucorrhœa at *par.* 158. The contagious gonorrhœa, or true gonorrhœa of both women and men, has also been shown to be a disease distinct from syphilis, and, therefore, the swelling of the testicles, the inflammation of the inguinal and prostate glands are not to be considered, as CHELIUS holds them to be, syphilitic, but merely sympathetic, and not requiring the treatment necessary for the cure of syphilitic affections. HUNTER observes, in reference to this circumstance:—"It sometimes happens, although but seldom, that the glands of the groin are affected in a common gonorrhœa with the appearance of beginning buboes, but which I suspect to be similar to the swelling of the testicle, that is merely sympathetic. The pain they give is very trifling, when compared with that of true venereal swellings, arising from the absorption of matter: and they seldom suppurate." (p. 61.) COOPER agrees with HUNTER that "buboes of this kind rarely suppurate, but only in very irritable constitutions. He distinguishes sympathetic from syphilitic bubo by "one gland only, in general, being enlarged in syphilis, but in a sympathetic bubo most frequently a chain of glands is affected. Of the two sets of glands in the groin, one just above POUPART'S ligament, and the other about two inches, or two and a half inches, below it; the lower tier is seldom enlarged from sympathy, the upper frequently." (p. 269.)

That discharges from both the male and female genitals have produced, in some instances, gonorrhœa, and in other chancres, every one who has had the slightest opportunity must have observed; and hence has arisen the opinion, long held by many surgeons, that the diseases were one and the same. But the examination of the vagina with the speculum, so largely practised, and on such good grounds strongly advocated by RICORD, explains the cause of these two sets of symptoms, by showing that in the vagina, and often even on the *cervix uteri*, chancres may exist, whence may be produced a discharge, which, without such examination, carelessly pronounced to be gonorrhœa, will cause chancre, or, if accompanied with gonorrhœa, may produce in one person chancre, in another gonorrhœa, and in a third both diseases at the same time, whilst the infecting party is presumed merely to have gonorrhœa. The use of the speculum, therefore, if only as a mean diagnosis, cannot be too strongly advised. In males it cannot be employed to examine the urethra; in such cases, therefore, it is well if the practitioner have any cause for suspicion, to inoculate the matter from the urethra into the patient himself. If the discharge be simply gonorrhœal, no inconvenience will ensue; but, if a chancrous sore should follow the inoculation, it is a proof that the disease is syphilitic, and that it must be treated accordingly.

For the examination of the public prostitutes RICORD lays down some rules which, under any circumstances where suspicious discharges from the female genitals exist, should always be followed. "The examination ought here," says he, "to be neither slight nor illusive; not only should the external part of the organs be examined, but also the internal and more concealed, for the source of the poison which it is wished to avoid, often lies in the depth of the vagina, on the *cervix uteri*, or even in its cavity; and in these cases neither an external examination, nor the *toucher* would suffice, and the speculum alone can warn them of their danger." (p. 255; Fr. edit., p. 540.)

This able surgeon has also shown the importance of inoculating discharges from the sexual organs, in regard to medico-legal questions as to venereal diseases. "In questions of rape, for instance, the consequences of syphilitic infection are often brought forward as a proof. Well! what practitioner would not, in the present state of science, seeing a man, affected with gonorrhœa, accused of having violated a woman actually infected with chancre, have regarded this pretended coincidence as a proof of great value? But when it is incontestibly known that chancre alone can produce chancre, if the gonorrhœal muco-pus of the individual supposed to be guilty, produces nothing upon inoculation, after having been properly tried, will it not be evident, in a case of recent infection, that he cannot be convicted? And, again, would it not be proved by the same mode of experimenting, that individuals accused of having communicated the pox, which must aggravate the position of all persons thus accused, have only caused by mechanical violence, or by the action of some morbid or normal secretion, simple inflammations." (p. 94; Fr. edit., p. 197.)

161. The *cure* of gonorrhœa is directed by its severity.

In slight cases the patient should drink whey, almond emulsion, linseed tea and such like, a mild diet used, abstinence from all irritating or heating things; rest, support of the testicles with suspensory bandage, frequent bathing of the penis in luke-warm water, which subsequently, also, for the sake of cleanliness, is to be continued.

If the inflammation and pain be more severe, the following additional treatment according to circumstances must be resorted to; bleeding, leeches at the root of the penis or its neighbourhood, and softening bread poultices.

Purgatives, recommended by many in gonorrhœa, are generally more hurtful than useful, and, if necessary on account of impurities in the bowels, should be of the mildest kind, as manna, tamarinds, and not salts, which irritate the urinary passages.

["The venereal inflammation (or rather the gonorrhœal inflammation—J. F. S.) is not kept up," says HUNTER, "by the pus which is formed, but, like many other specific diseases, by the specific quality of the inflammation itself. This inflammation, however, it would appear, can only last a limited time; the symptoms peculiar to it vanishing of themselves, by the parts becoming less and less susceptible of irritation. This circumstance is not peculiar to this particular form of the venereal disease; it is perhaps common to almost every disease that can affect the human body. * * * As the living principle in many diseases is not capable of continuing the same action, it also loses this power in the present, when the disease is in the form of a gonorrhœa, and the effect is at last stopped, the irritation ceasing gradually. This cessation will vary according to circumstances; for, if the irritated parts are in a state very susceptible of such irritations, in all probability their action will be more violent and continue longer: but, in all cases, the difference must arise from the difference in the constitution, and not from any difference in the poison itself. The circumstance of the disease ceasing spontaneously, only happens when it attacks a secreting surface and when a secretion of pus is produced. * * * Gonorrhœa cures itself, whilst the other forms of the disease require the assistance of art. (pp. 36, 7.) Gonorrhœa may be cured while there is a chancre, and *vice versâ*." (p. 38.) (It is very remarkable that, with these facts staring him in the face, HUNTER should have persisted in his opinion that gonorrhœa and chancre were one and the same disease.—J. F. S.) "How far the gonorrhœa in women is capable of wearing itself out, as in men, I cannot absolutely determine; but am much inclined to believe that it would: for I have known many women who have got rid of a violent gonorrhœa without using any means to cure it; and indeed the great variety of methods of cure made use of in such cases, all of which cannot possibly do good, though the patients get well, seems to confirm this opinion." (p. 59.)

HUNTER has made an observation in regard to gonorrhœa, which every one who has had the least experience must accord with, viz., that it is "the most uncertain in the cure of any of the forms of this disease; many cases terminating in a week, while others continue for months, though under the same treatment. The only thing necessary to be done for the cure is to destroy the disposition and specific mode of action in the solids of the parts, and as that is changed the poisonous quality of the matter produced will also be destroyed." (p. 75.) This latter observation does not very well tally with what he says almost immediately after:—"We have no specific medicine for gonorrhœa," although he comforts himself with "it is therefore very reasonable to suppose that every such inflammation gets well of itself; yet, although this appears to be nearly the truth, it is worthy of consideration whether medicine can be of any service in this form of the disease. I am inclined to believe it is very seldom of any kind of use, perhaps not once in ten cases." (p. 75.) "I believe," Hunter subsequently observes, "the soothing plan is best at the beginning. * * * In cases where the symptoms run high, nothing should be done that may tend to stop the discharge, either by internal or external means, for by this nothing would be gained; as merely stopping the discharge does not put an end to the inflammation. The constitution is to be altered, if possible, by remedies adapted to each disposition, with a view to alter the actions of the parts arising from such dispositions, and reduce the disease to its simple form. If the constitution cannot be altered, nothing is to be done but to allow the parts to tire themselves out by a continuance of the same action." (p. 77.)

The employment of stimulating injections of various kinds, for the purpose of checking the discharge in gonorrhœa, has been a favourite practice with many surgeons, and even so long back as John of Arden they were used, but of a very mild character, as shown by his following prescription :—

"*Pro morbo qui dicitur Chaude-pisse.*—Accipe pursillam et coque in aqua donec in mucilaginem vertatur, quæ mucilago cum oleo rosæ et violæ fortiter agitetur addito lacte mulieris puellam nutrientis ana, in quo liquore dissolvatur camphoræ uncia una et pro syringam (injectionem) initiatur. Mucilago est quæ quædam viscositas admodum galature piscium vel earum anglicè gelee."—*MSS. Sloane*, 2002.

Translated by E. H., as follows : —

"Seethe the parsley in water till it come to a mucilage, that is, till the water be made green and slimy, and the substance of the herb be consumed. Then temper with that mucilage oil of roses and oil of violets and the milk of a woman nourishing a maiden child, and then dissolve therein one ounce of camphor, and by a syringe administer it."—*MSS. Sloane*, 2271.

Beckett mentions another prescription, which, however, I have not found :—

"*Contra Incendium.*—Item contra incendium virgæ virilis interius ex calore et excoriatione fiat talis syringa lenitiva. Accipe lac mulieris masculum nutrientis et parum zucarium, oleum violæ et ptisanæ quibus commixtis per syringam infundatur et si prædictis admiscueris lac amygdalarum melior erit medicina."

Abernethy objects to any attempt at checking gonorrhœa. "By endeavouring to arrest the disease in its progress," says he, "we are likely to induce irritation in the remote part of the urethra, and other affections; whereas if we merely soothe the malady, and allow it to take its natural course, it declines in due season, without, in general, producing any material injury to the part affected, or to any other in its vicinity." (p. 278.)

But patients will not be content to wait till a clap shall "decline in due season," although recommended so to do on the authority of Hunter and Abernethy. And it therefore becomes necessary to resort to some treatment for shortening the disease, and to relieve the often severe symptoms.

Abernethy's soothing practice is especially good when the inflammatory stage is very active, and is not unfrequently sufficient under ordinary circumstances; for Hunter's supposition, that "every such inflammation gets well of itself," is often true enough. Abernethy's plan consists in "bathing the perinæum and genitals with tepid water, by means of the bidet and sponge, for five or six minutes every night and morning; at the same time desiring them to wash beneath the fore-skin, so as to remove every thing lodged there, and to wash this part drawn well forward, and to protect the orifice of the urethra from mechanical irritation. * * * I also recommend those who are affected with clap to be very attentive to keeping their bowels in a regular state, because any inquietude in the bowels is likely to produce an irritable state of the urinary organs." (p. 278.)

I formerly adopted this soothing practice almost entirely, prescribing the following mixture :—℞ *magnes. sulph.* ʒi., *potass. nitr.* gr. v., *acac. pulv.* ʒi., *tinct. hyoscyam.* ♏v., *aq. destill.* ℥i., *ter quaterve in die;* under which treatment, either without or with mild injections of sulphate of zinc when all scalding had subsided, the disease was generally cured in ten days or a fortnight. Or I gave pills of the following composition :—℞ *tereb. chiæ* ℈ij., *pulv. rhei* ℈i., *syr. q. s.*, *et in pil.* xij. *dividend.;* four of these, twice a-day, were first given, and the number increased afterwards to six or eight as might be needed. But, of late, I have only employed the injection of a very mild solution of nitrate of silver, three grains to sixteen ounces of water, before the scalding ceases, and even when there is inflammation of the testicle, twice or thrice a-day, and I have never yet witnessed any ill effects; but the contrary, as, in two or three days the gonorrhœa is usually stopped.

Carmichael recommends injections into the male urethra twice a-day of a solution of nitrate of silver, ten grains to an ounce of water, for the purpose of cutting short the development of a gonorrhœa. I should be very sorry to follow such practice, as I should fear the almost certain production of stricture. But, if I used the nitrate of silver for this purpose, I should certainly, with Ricord, prefer the following method which he has employed, but does not speak of either in praise or dispraise. "I introduce into the urethra," says he, "Lallemand's caustic holder, and then, exposing the caustic, I withdraw it, at the same time giving it a rotatory motion, so as superficially to cauterize the whole of the mucous membrane of the urethra. If, after this first cauterization, too much inflammation supervene, recourse must be had to antiphlogistics, otherwise a similar cauterization should be made three or four days after the first." (p. 335; Fr. edit., 710 .)

The following was the plan adopted for many years by Astley Cooper:—In the first week, during which there is much inflammation, a draught of *magn. sulph.* ʒij., *inf. senn.* ℥jss., thrice a day, to produce active purging: diluting drinks of capillaire or tea, of which too much cannot be taken, and in which is to be taken daily *potass. carb.* vel *sod. subcarb.* ʒij. He found lime water a very excellent diluent, but did not care about mucilage, and considered the use of soda water very doubtful. If there were much scalding in passing the urine, or the pain from chordee were severe, he gave with advantage of *liq. potass.* ♏xx., *ext. conii.* gr.v., *ex mist. camph.* thrice a-day. The penis was kept for a long time in warm water, as a bath, to relieve the inflammation, and after a week overlaid with lint dipped in Goulard's wash. Three or four days after which, when the inflammation had greatly subsided, he gave a mixture of *bals. copaib.* ℥j., *mucil. acac.* ℥j., *mist. camph.* ℥iv., of which half an ounce was given night and morning. After persisting for two days longer in the use of this mixture, and the discharge being considerably lessened, he employed injections, three or four times a-day, of *liq. plumb. subacet. dilut.* ℥iv., *c. zinci sulph.* gr.vi. By this plan a gonorrhœa is safely and expeditiously cured. If the clap be a second or third, the balsam of copaiba may be given at once, and speedily stops the discharge. The strength of injections should be gradually increased, so as to produce slight irritation; but it is better to vary the kind of injection, *cupr. sulph.* gr. ss., *aq. distill.* ℥j., or *hydrargyr. oxymur.* gr.j., *aq. distill.* ℥xij. The use of bougies, though at first increasing the discharge, is often successful if accompanied with injections. (p. 193.)

In reference to the cure of gonorrhœa, Astley Cooper observes:—"It is difficult in proportion as the constitution of the patient is disposed to strumous affections. If a patient have pimples in his face, enlargement of the glands of the neck, a thin, delicate skin, and irritable fibre, you may expect to have great difficulty in curing him of gonorrhœa." (p. 191.)]

162. In very painful chordee (1) bleeding, leeches and soothing poultices must be employed. If the pain be not thereby diminished, if the patient be not plethoric, and the pain rather spasmodic, opium, hyoscyamus, camphor, poultices of narcotic vegetables and soothing clysters may be used with due carefulness. If, during the chordee, bleeding occur (2), the symptoms are usually much diminished; but, if it continue and become exhausting, attempts to allay it must be made by compression of the penis, by injection of a solution of gum arabic, and in very extreme cases by astringent injections.

[(1) Painful erections are generally controllable by the administration of a full dose of opium before retiring to rest, and by light bed-clothing. The same is also very useful in chordee, and a bottle of cold water placed between the legs, against the perinæum is a very efficient local application. Smearing the chordeed part with extract of belladonna is often useful, and, in obstinate chordee, I have used mercurial friction with advantage, even before it has become chronic. Astley Cooper recommends enveloping the penis at night in lint dipped in Goulard water, or the use of evaporating lotions. Ricord thinks camphor with opium either as a pill or an enema the most powerful internal remedy, and my own observation confirms his opinion. Hunter says, that "in relieving chordee, or the remains of it, which appear to arise from spasm, he has known the bark of great service." (p. 96.)

(2) When bleeding from the urethra occurs, it is generally rather beneficial than otherwise, and only requires control when severe. This may be effected by leading up the finger from the perinæum against the under surface of the urethra, till the point whence the blood escapes is found. The penis is then to be grasped between the thumb and

finger for a quarter of an hour or twenty minutes, which is generally successful. **Hunter** says, in such bleedings, he has "seen balsam of copaiba given internally of service," and supposes that "all the turpentines would be useful." (p. 95.) If, as **Ricord** states, though I have not observed it, "frequently the hæmorrhage return the first time the urine is passed; then, however objectionable it is to place a foreign substance in the inflamed urethra, we must introduce a bougie, which by compressing the vessels stays the effusion of blood. Sometimes additional circular external compression is required; but great caution must be used in its application. Generally this bougie may be removed after twenty-four hours; but, when the hæmorrhage has been great, and the instrument does not excite much pain, it is advisable to leave it a day or two longer. If the bougie have been removed too soon, and the hæmorrhage reappear, it must be reapplied, if it be not merely a sanguinolent discharge." (p. 339; Fr. edit., p. 717.)]

163. If the pain subside and the discharge diminish, a suitable treatment, with a slightly improved diet, with the avoidance, however, of all heating things usually suffices for the perfect cure. The frequent use of diluted fluids must be forbidden, lest by their too great relaxing power they might give rise to gleet. This must be especially attended to in otherwise flabby and scrofulous persons. For such cases we may recommend the use of *juniper rob*, *dulcamara*, *gum guaiacum*, *decoction of woods* and the like. If for a long time there remain a sparing discharge of serous fluid, slightly astringent injections of acetate of lead, sulphate of zinc, sublimate and so on, with opium, may be used to prevent the discharge becoming chronic.

164. In those cases in which a syphilitic form of gonorrhœa is suspected, after the inflammation is diminished or removed, mercury must be used for some time, or, together with a strengthening and tranquillizing diet, the use of decoction of woods must be persisted in, for the purpose of preventing the origin of general syphilis.

[It having been already shown that gonorrhœa and syphilis are distinct diseases, and do not generate each other, the treatment just mentioned is superfluous.—J. F. S.]

165. The treatment of gonorrhœa in women is precisely the same as that in men; but so strict an antiphlogistic management is not requisite; in general mild injections or steaming is sufficient to diminish the inflammation. Astringent injections are to be used and made stronger, if the discharge be inclined to become chronic. The excoriated parts are to be covered with charpie spread with citrine or red precipitate ointment. The internal use of mercury, or the use of decoctions of wood, with strict attention to diet is then particularly necessary.

[I have never known it necessary, on account of the acuteness of gonorrhœal symptoms in women, to apply leeches, as recommended by **Ricord**; but, commonly, in all stages, unless there be inflammation and swelling of the external parts, employ injections of nitrate of silver, ten grains to an ounce of water once a-day; taking care that the vagina being well washed out, none of the injection should be left behind. This practice is fully confirmed by **Ricord**'s experience. He says:—"Sometimes acute gonorrhœa in women, whether complicated or not, resists the most judicious soothing treatment, and is aggravated by the use of mercurials. In some of these cases, in which the red and turgid mucous membranes afford a copious purulent discharge, attended with acute pain, which neither rest, depletion, emollients, nor narcotics can assuage, I have obtained astonishing results from the use of nitrate of silver. A superficial cauterization with solid nitrate of silver, or a solution of it, applied by means of lint, has favourably modified the inflamed surfaces, and produced a solution of the disease. After the use of the cautery, a plug of dry lint must be employed to prevent the contact of the walls of the vagina." (p. 324; Fr. edit. p. 683.)

Than these modes of treatment I do not know any better. Injections of acetate of lead, of decoction of tormentilla, of oak or elm bark and alum, are commonly recommended, but I do not consider them very efficient.

It must be borne in mind, in regard to stimulating injections, that some constitutions are more excitable than others, and, therefore, if the injections used excite considerable pain in the vagina, they must be either diminished in strength or entirely left off. **Home** (*a*) mentions the cases of two young women, who having been infected with gonorrhœa by the men who debauched them, and having used injections of the strength generally used for common women, had "the sides of the vagina united together by the adhesive inflammation." (p. 90.) Such cases are very rare, but serve as a caution in the use of these remedies.

If the inflammation be very severe, **Ricord**'s plan of introducing a plug of lint, dipped in emollient narcotic liquid, and renewed twice or thrice a day, so as to act as a poultice, may be useful, if, as he says, it can be effected without pain.

Ricord mentions that "some discharges, which resist all the above applications, seem to be maintained by the contact, even of the mucous membranes and the depth of the parts continually placed in the unfavourable conditions of heat and moisture." For these he has found good success by "filling the vagina, without much distending it, with dry lint, renewed two or three times a-day, according to the quantity of the discharge, which, in the cases that terminated successfully, was white and milky, and proceeded from the vagina alone." * * * "Ulcerations and papulous granulations are to be cauterized with nitrate of silver, which is to be preferred, or with nitrate of mercury on lint." (p. 326; Fr. edit., p. 686.)

Of ulcerations of the mucous membrane of the womb, I have no personal experience; but **Ricord** says that, "we must here, as in the ulcerations of other parts, modify the surfaces in a more powerful manner; but the greatest precautions are necessary in cauterizing the interior of so delicate an organ, the reaction of which would be so powerful; for, whilst the strongest caustics applied to the cervix generally produce no pain, fluids scarce possessing any caustic properties, being introduced into the cavity of the uterus, may cause the most serious consequences." Of which he instances, from the use of an injection of one part of nitrate of mercury to eight of water, very violent hysterical attacks in some patients, and, in one, "a cerebral congestion which caused a momentary apprehension of apoplexy. These symptoms, which all arose a few minutes after the injections, yielded rapidly to antispasmodics, and, in the case with the cerebral congestion, on a quantity of blood being taken from the arm." He then used one part of nitrate of mercury to twelve of water; but these injections were not always unattended with pain, or some nervous reaction of a hysterical character. I then substituted," says he, "six grains of nitrate of silver to the ounce of water, and found that, in some instances, a chronic purulent uterine discharge was cured after two or three injections." (p. 327; Fr. edit., p. 689.)

When "vegetations originate in the interior of the urethra, constituting what were formerly termed caruncles and carnosities, they maintain discharges which cease when they are destroyed by incision or cauterization." (p. 328; Fr. edit., p. 691.)

When the urethra is affected with gonorrhœa, injections are recommended by **Ricord** to be used as in men, the fluid being prevented from passing into the bladder, by pressing the back of the urethra against the pubes.]

166. If the discharge become chronic, it is usually long-continued, and, upon the least excess, the smarting and burning in making water return. The many remedies advised against gleet must be used with due attention to the causes from whence it has originated. It may be caused by *weakness*, by a *morbidly increased insensibility*, and by *organic changes in the mucous membrane of the urethra.*

In the *first* case, balsamic stimulating remedies are to be employed, balsam of copaiva in gradually increasing doses, gum kino; astringent injections of acetate of lead, sulphate of zinc and copper, of sublimate; washing the penis with spirituous fluids and so on. In the *second* (which in sensitive persons sets in very soon, if the inflammatory stage of the gonorrhœa be improperly treated) all stimulating and exciting remedies will be injurious. **Haller**'s acid in a decoction of salep must be administered internally; in very high sensibility a dose of opium, or of *aqua lauro-cerasi* in emulsion, must be given frequently during the day. In this case only are injections of decoction of red foxglove, of poppy-seed emulsion, with laurel water, with opium and so on of service. The patient

(*a*) Note in **Hunter** on the Venereal.

must carefully avoid every excess. In the *third* case, when ulceration, stricture, or diseased changes of the prostate are present, the patient complains of pain at a certain point when touched and in making water. If the discharged fluid be frequently streaked with blood, it indicates an ulcer, in which case, a suitable antisyphilitic treatment, sublimate as injection, and the use of bougies, is necessary.

[Chronic gonorrhœa is commonly known by the name of *Gleet*, and is generally a thin transparent discharge unattended with pain, but under any excitement or excess it becomes white, yellow, or greenish, and, if the excitement be great, even tinged with blood; in fact, the gonorrhœal inflammation is re-excited. Astley Cooper considers it to "proceed from the lacunæ of the urethra," in other words, from the usual seat of gonorrhœa. But it is often a concomitant of stricture, and sometimes the use of a bougie will reproduce inflammatory action, and an increased discharge, capable of bringing on a yellow discharge, with pain in making water in the female, as happened in a case mentioned by Astley Cooper. (p. 272.) And he observes:—"Gleet is said to be that stage of gonorrhœa where the discharge ceases to be infectious. I doubt whether there is such a complaint as gleet, according to this definition, for I cannot help believing that a gonorrhœa never ceases to be infectious. * * * I doubt whether a gonorrhœa ever loses its power of causing infection as long as any discharge from the urethra remains." (p. 270.) He mentions instances, the first, in which infection followed a gonorrhœa of five months and three days, and the second after fourteen months. But Hunter gives a more remarkable instance, in which a girl, who had been for two years in the Magdalen Hospital, infected a person immediately after leaving that house. (p. 40.) And Tyrrel (*a*) says, that he "saw a case once, where the gleet had existed for six or seven years, and had resisted various means, both local and constitutional, that had been tried for its cure." He tried in this case, "touching the under part of the urethra, just opposite the frænum, with caustic. This application, for the time, stopped the discharge, but, as soon as the slough came away, it returned just as before, in the quantity of four or five drops a-day." (pp. 566, 7.) Hence it appears that the disease will continue a great length of time.

It is said that gleet resulting from gonorrhœa, may be distinguished from gleet accompanying stricture; but I very much doubt it, and I think Cooper's case, above cited, in which the man, whose stricture was irritated by the bougie, clapped his wife, supports my notion. Tyrrel, however, mentions the distinction between the two as follows:—"If the gleet is merely gonorrhœal, there will be a tingling sensation behind the frænum, and, if the patient indulges in excess of any kind, or takes too violent exercise, this, together with the quantity of the discharge, will be increased. If you ask the patient how he voids his urine, he will say, that the stream is free and uninterrupted to near the extremity of the passage; then, that it stops for an instant, and afterwards passes very well; this symptom arises from the accumulation of the discharge near the lacunæ. On the contrary, if there is stricture, the patient voids his urine very badly; and this is influenced very considerably by change of weather, or by irregular conduct on the part of the patient; and, if you inquire more minutely, you will find that the stream of urine is small and completely twisted." (p. 567.)

Astley Cooper speaks of the possibility of confounding gonorrhœa or gleet with abscess in the lacunæ; the latter, however, he observes, "may be always known by its being absent for a week or more, and then flowing profusely, but not so in a gonorrhœa. And the matter from an abscess of the lacunæ is not infectious, whilst the discharge, which begins a gonorrhœa and terminates in a gleet, never loses its power of producing infection." (p. 271.)

In deciding upon the cure of gleet, let it never be forgotten that, so long as only six or eight drops of the discharge are observed during the day, or even if the lips of the urethra be merely moist with it, on rising in the morning, the cure is not effected, and the person ought not to marry, or he will infect his wife.—J. F. S.]

Astley Cooper's treatment of gleet consisted in the use of the following medicines:—℞ *spir. æther nitr.* ʒij., *bals. copaib.* ʒi., *muc. acac.* ℥i., *mist. camph.* ℥iv.: *ft. mist. cujus capiantur coch. magn. bis terve indies*; or, should that fail, ℞ *pulv. lytt.* gr.¼, *tereb. chiæ* gr.v. *pro pil. bis terve quotid. sumend.* As to local treatment, he employed bougies, either simply smeared with oil, or with *ung. hydr. mitius*, or *ung. hydr. nitr. oxyd.* The latter first in proportion of a scruple of the salt to an ounce, and gradually increased in strength; using at the same time injections, "from which there would be no danger of stricture, as the bougie would prevent it." The injection he preferred was *hydrarg.*

(*a*) Clinical Lecture on Gleet; in Lancet, 1824. vol. ii.

bichlorid. gr.¼, *aq.* ℥iij., and gradually increased up to half a grain to an ounce. (p. 272.)

A generous diet is necessary in cases where the gleet continues, and not unfrequently it is found advantageous for the patient to take wine. Balsam of copaiva, either in mixture or in capsules, is often very serviceable in addition to injections, of which I prefer that of nitrate of silver. When the gleet continues very obstinate, there is reason to suppose, as stated by HUNTER, that stricture exists, and it is then necessary to use the bougie.

RICORD mentions that "inoculation of a new gonorrhœa has been advised, and is still perpetrated by many practitioners, either to cure a chronic discharge, or to combat, by revulsion, symptoms which gonorrhœa may produce, such as epididymitis, ophthalmia, &c. Some, in this case are content with advising a new infecting coition; others make a kind of inoculation with the muco-pus of gonorrhœa, carried on a probe into the urethra, or applied to the mucous membrane it is wished to infect, by means of a bit of lint which is impregnated with it. * * * However, were I not convinced that the cases in which it is useful to recall an old discharge, or develop a new one, are as rare as some persons think them frequent, and that they have either aggravated the disease they wish to combat, or given it a new complication, I would not apply the muco-pus of a gonorrhœa of one individual to another before having ascertained, upon the one from whom it is taken, that it produces nothing when inoculated with the lancet; otherwise, without this precaution, a patient with gonorrhœal symptoms might be affected with masked chancres, (*chancres larvés*,) and communicate to an individual, who till then had only a simple catarrhal affection, without further consequences, all the formidable chances of syphilis." (p. 89; Fr. edit., pp. 188, 9.)

I have noticed these proposals for the cure of obstinate gleet, or other consequence of gonorrhœa, merely to point out their absurdity; as I presume no one, excepting those whose treatment of disease is founded on the *similia similibus, eadem iisdem* principle, could seriously think of adopting them. The moral conduct involved in the attempt to acquire a new gonorrhœa to put an end to an old one, is about on a par with that of commerce with an uninfected person for the same purpose, (a vulgar notion which was formerly held,) and the benefit from either alike.—J. F. S.]

167. The mode of treating gonorrhœa already mentioned is founded upon the various degrees and nature of this complaint. Of late *cubebs* have been recommended by many practitioners as the most effectual remedy against it, and, according to my own experience, I must accede to the good report of it given by others, and especially by DELPECH. This remedy operates upon the gonorrhœa not merely, as many suppose, when the inflammatory period has passed over, but it performs its good offices in every stage of the disease. The principal point in the use of cubebs is, that they should be genuine, and given in sufficiently strong doses. With small doses of cubebs the gonorrhœa is commonly increased. At the onset, at least half an ounce a day should be given, which should be much increased if no special symptoms ensue. In many cases DELPECH gave four doses daily of two or three drachms each without producing any peculiar symptoms; it is, however, better to divide the doses and give them more frequently. If required to act briskly and for some time, it is most advisable to give a dose every three or four hours, and meal times should be regulated accordingly, or a dose taken even during the night. The usual consequence of this remedy is a gentle warmth in the belly, not always accompanied by an increase of thirst, which generally ceases in a few days, even when the dose of cubebs is increased. If therefore this symptom pass by, it is not necessary to discontinue the remedy; but, if it continue, and pain in the belly be produced, the doses must be diminished to two or three; it may then do good, but its operation on the disease is more tedious. In many cases the remedy produces frequent, thin stools with or without pain in the belly, very rarely accompanied with tenesmus, but never with discharge of bloody mucus. In such cases the remedy must be withheld,

solid food forbidden for some days, mucilaginous drinks taken, and then the medicine resumed in the same doses as before, or in smaller ones. Frequently this symptom is the consequence of gastric irritation, which may be relieved by an emetic, and then the earlier or stronger doses may be used. Some persons bear this remedy only when given at meal-time, or when food is taken with it. In many cases where it cannot be endured balsam of copaiva, according to Delpech's experience, is useful; but, when that causes purging, cubebs must be employed. Frequently do the cubebs produce no satisfactory alteration; but in no instance is the disease thereby rendered worse. In recent gonorrhœa the burning, the heat, the not very severe pain, and the discharge soon diminish, the latter becomes serous, and in two or three days the whole has passed off. The same occurs with the slighter claps, even when they are of longer standing. Three doses daily of two drachms each are sufficient in these cases. More severe gonorrhœæ in the second or third week, with severe pain, chordee, and so on, yield less easily and only to larger doses. Improvement also takes place very rapidly; the chordee frequently continues longest, but often subsides after a blister, when every thing else fails. Also in those cases in which the inflammation has extended to the neck of the bladder accompanied with discharge mixed with blood, with severe inflammation, with swelling of the prostate glands, if the pain was exceedingly severe, and in swelling of the testicle, this remedy was very efficient. Old and painless swellings of the testicle remaining after acute affection, which were connected with symptoms of general infection, and had even withstood antisyphilitic treatment, yielded to the use of the cubebs, even although general syphilitic disease continued. The same occurred in the swellings of the inguinal glands, if depending on gonorrhœa. During the use of cubebs a mild diet and rest must be observed. The remedies must be continued for at least eight days after all symptoms have disappeared.

Delpech has disproved by numerous observations that cubebs can produce inflammation of the testicles as by some supposed. Previous to using cubebs Delpech had given balsam of copaiva in large doses in all stages of gonorrhœa with good effect. Both remedies, according to recent observations, contain an analogous substance. Perhaps the inefficiency of cubebs, when properly administered, may prove the peculiar syphilitic nature of the gonorrhœa. In order to prevent the general infection, Delpech, when the gonorrhœal inflammation is not too great, uses at the same time twelve to fifteen rubbings-in of half a drachm of mercurial ointment night and morning on both sides of the penis.

Velpeau (*a*) employs cubebs and balsam of copaiva in clysters; two, four, six, or eight drachms rubbed down with yolk of egg or with decoction of marsh-mallows.

Michaelis (*b*) has tried cubebs on many patients who were suffering from gonorrhœa, and only in one single case, in which gleet had existed for a short time, did he observe a cure. Just as inefficient did he find it in the whites and in chronic catarrh of the lungs.

Richon and De Salle have given, as they assert, with great effect, thirty drops of tincture of iodine night and morning in gonorrhœa. In some cases, leeches were first applied to the urethra, and an antiphlogistic diet coupled with it.

[Astley Cooper was a great advocate for the use of cubebs. He said it " appears to produce a specific inflammation of its own on the urethra, which has the effect of superseding the gonorrhœal inflammation. * * * In the very early stages of gonorrhœa, when the inflammation is just beginning, it often succeeds in removing the disease in a very short space of time." But he observes :—" I do not say that it would be advisable to employ this remedy at once for a first gonorrhœa, where the symptoms of inflammation run very high in a young and irritable person; it is better not to begin with the use of it until a week or ten days have elapsed, and the inflammation is considerably reduced." He thinks it " a most useful remedy also for the cure of gleet, as it is called,

(*a*) Archives Générales de Médecine, Jan. 1827. (*b*) Journal of Graefe und Walther, vol v. p. 70.

where gonorrhœa has continued for a length of time." And also that "the greatest advantage may be derived from combining its use with that of copaiba, when the balsam alone is beginning to lose its effect," and he gives it as a mixture, viz., "An ounce of the balsam of copaiba, an ounce of the mucilage of acacia, two drachms of cubebs, in four ounces of camphor mixture." (pp. 146, 7.)

For my own part, I may state that I have used cubebs very freely in all stages of clap and gleet, but not with the advantage attributed to it. I do not think it superior to other of the usual treatments, and it often produces much annoyance from loading the stomach. If used, I think it is better to employ it in the shape of extract, as pills, in which form, also, copaiba is prepared, and may be used in like manner. But the more common mode now of exhibiting copaiba in private practice is in little capsules of caoutchouc. Some years ago we were in the habit of using, at St. Thomas's Hospital, the following copaiba mixture, which was very efficacious, and had the advantage of rarely disagreeing with the stomach, a matter of much consequence if the medicine be long persisted in:—℞ *bals. copaib.*, *spir. æther. nitr.* āā ♏xl., *tinct. hyoscyam.*, *liq. potass.* āā ♏xx., *ex aquâ ter die sumend.* If necessary to increase the quantity of the balsam, a proportionate quantity of mucilage is added.—J. F. S.]

168. *External Gonorrhœa* (*Gonorrhœa Glandis*, *Balanitis*, *Posthitis*, Lat.; *Eicheltripper*, Germ.; *Blennorrhagie externe*, Fr.) is either a mere consequence of want of cleanliness, in which case the sebaceous matter secreted by the odoriferous glands collects and becomes acrid; hence it particularly occurs with a lengthened narrow prepuce, or is consequent on syphilitic infection. The latter may always be guessed at when it follows suspicious connexion, is connected with excoriation, and is obstinate.

[HUNTER believes, that, "when the disease attacks the glans and other external parts, as the prepuce, it is principally in those persons whose glans is commonly covered with the prepuce, and it is principally about the root of that body and at the beginning of the prepuce, the parts where the cuticle is thinnest, and of course where the poison gets most readily to the cutis; but, sometimes, it extends over all the glans and also the whole external surface of the prepuce. It produces there a soreness or tenderness, with a secretion of thin matter commonly without either excoriation or ulceration. I am not certain, however, that it does not sometimes excoriate those parts; for I once saw a case where the whole cuticle came off the glans." (p. 44.) I have seen this condition not at all unfrequently; it is quite distinct from any syphilitic affection. Excoriation with little or no discharge often happens to young persons, even children, simply from the acridity of the secretion of the odoriferous glands; and I have seen it produce violent inflammation and swelling of the prepuce, and threatening mortification. It frequently recurs and is very troublesome.—J. F. S.]

In *Gonorrhœa of the Glans which is not syphilitic* the observation of great cleanliness, frequent washing of the glans with tepid milk, lead wash, and so on, are sufficient for the cure. In the syphilitic form, mercury must be used both externally and internally.

[The simple treatment recommended by **Chelius** is generally quite sufficient; mercury is never needed. " When the glans can be uncovered and the inflammation is not excessive," **Ricord** says, the method he has " found best succeed, is passing the pencil of nitrate of silver gently over the diseased surfaces, so as to cauterize them superficially, after which it is sufficient to put a bit of dry lint round the glans and draw the prepuce over again. Lotions of lead wash or cold water are to be applied over." (p. 331; Fr. ed., p. 669.) This is very good practice, but I commonly use only a little black wash. —J. F. S.]

[168*. *Gonorrhœa of the nose* sometimes occurs during gonorrhœa of the urethra, or whilst there is an enlargement of the testicle from the same cause. The Schneiderian membrane is tender over its whole surface, but not painful; is of a deep red colour, but not ulcerated; and there is a free discharge similar to that of clap.

This disease was first noticed by **Benjamin Bell**, and he mentions two cases of it: in the first, " the discharge from the urethra lessened before the testes became inflamed, and, on this taking place from the nose, it ceased entirely." It was treated with an astringent lotion and the insertion of sponge moistened in it up the nose, and cured in a few days. In the second case, " the discharge took place during the continuance, and had existed many years, and, although it had frequently become less, it never disappeared entirely." Various attempts at its cure were made without success, " and, though no other symptom appeared, he was advised to undergo a course of mercury; but no advantage ensued." (pp. 29, 30.)—J. F. S.]

169. In the treatment of *Gonorrhœa*, of which the ground is a *gouty* or *herpetic* disease, and so on, that given for the non-syphilitic gonorrhœa is suitable; but in these cases the inflammation is usually long-continued, even when the disease has run into a chronic form. Then especially must be employed purging, warm bathing, preparations of sulphur, antimony, and so on.

V.—OF INFLAMMATION OF THE TESTICLE.

170. *Inflammation of the Testicle* (*Inflammatio Testiculi*, *Orchitis*, *Hernia humoralis*, Lat.; *Hodenentzündung*, Germ.) may be produced by different causes.

[" In some instances," as observed by **Benjamin Bell**, and it might be added, specially during or after gonorrhœa, " both testicles swell. They seldom, however, swell both at once; but the swelling, on leaving one testicle, is very apt to go to the other; and when both have, in this manner, been affected, they sometimes swell alternately for a considerable time together. I have known this happen for the space of a year and upwards, where the patient, during the whole period, was never completely free of the disease." (p. 337.)]

First. It occurs most frequently in gonorrhœa, either with a very high degree of inflammation, with dragging pains in the belly and pelvis if the patient move about much, and the testicles be unsupported; in which case, the inflammation extending to the testicles, first attacks the epididymis, and next the whole gland; or it confines itself merely to the former (*Epididymitis*;) or it may be produced when the inflammatory symptoms have declined, by any irritation of the testicle, violent exercise, for instance.

[**Hunter** remarks very justly, of the singularity of swelling of the testicle not coming on " when the inflammation of the urethra is at its height; he thinks it happens when the irritation is going off, and sometimes even after it has entirely ceased, and when the patient conceives himself to be quite well." (p. 60.)]

Second. It may be a symptom of general syphilis.

[Even **Hunter** says:—" I believe the swelling of the testicle, like the affection of the bladder, and many of the symptoms mentioned before, is only sympathetical, and *not to be reckoned venereal;* because the same symptoms follow every kind of irritation on the urethra, whether produced by strictures, injections, or bougies. It may be observed here, that those symptoms are not similar to the actions arising from the application of the true venereal matter, whether by absorption or otherwise; for they seldom or ever suppurate, and when suppuration happens, the matter produced is not venereal." (p. 57.)

ASTLEY COOPER holds with CHELIUS's opinion. He says:—"I have seen this organ, (the testicle) so frequently enlarged during the existence of secondary symptoms of syphilis, more especially in combination with a cutaneous and periosteal venereal affection—and have observed it additionally swollen and painful in the evening, although relieved by the recumbent posture in bed—and known it yield so easily and readily to the influence of mercury, and just in proportion to the disappearance of the venereal symptoms, that I think it quite unreasonable to doubt its liability to be affected by the venereal poison. * * * The testicle and epididymis become four or five times their natural size. The pain which accompanies the disease is not severe, but it is increased towards evening. When one testicle is enlarged, the other is apt to become affected; and, I think, in the majority of cases, that the disease exists in both testicles. * * * It is rarely a concomitant of the syphilitic sore throat only; but it frequently accompanies the venereal eruption and periosteal inflammation. The distinguishing mark of this disease from the simple chronic enlargement of the testicle, will be found in its succeeding syphilitic symptoms, and often in its being combined with those I have mentioned, as well as in its obeying the law of syphilis, viz., of its being liable to an evening exacerbation. (pp. 102-4.) I am sure I have seen such enlargements of the testicle combined with syphilis, and that their best mode of treatment is similar to that for iritis. * * * I feel assured that the testicle becomes affected during the progress and influence of the syphilitic poison upon the body, in some persons; and that mercury, whilst it subdues the other symptoms, is also the only cure for this disease." (p. 110.) Eight cases are given by COOPER in support of his opinion of the syphilitic character of this enlargement. RICORD also agrees with COOPER: he says:—"Syphilitic sarcocele must not be confounded with gonorrhœal epididymitis; * * * it is seldom found as a sole sign of a secondary affection, but is commonly preceded or accompanied by other symptoms of general infection; it frequently attacks only one testicle at a time. * * * The disease is frequently accompanied or preceded by nocturnal pains in the loins. The induration may have its seat in the epididymis or the cord; but it is the substance of the testicle which is almost invariably affected. Syphilitic sarcocele may often be complicated, which renders the diagnosis very obscure." (p. 303; Fr. edit., p. 640.)

Notwithstanding these high authorities, I must confess I have great doubt as to the swelling of the testicle depending on a syphilitic cause.—J. F. S.]

Third. It may be produced from external injury.

Fourth. From cold, especially in persons who sweat much, on the perinæum, and on the insides of the thighs.

Fififth. Violent exertions may produce increased congestion of blood to the testicle and, its return being impeded, may excite inflammation.

[HUNTER says he has "known the gout produce a swelling in the testicle, of the inflammatory kind, and therefore similar to the sympathetic swelling from a venereal (gonorrhœal—J. F. S.) cause, having many of its characteristics." (p. 60.)

ASTLEY COOPER mentions enlargement of the prostate gland in old age, as occasionally accompanied with swelling of the testicle; also inflammation of the neck of the bladder; a stone passing through the ureter, or pressing upon the commencement of the urethra from the bladder. This latter circumstance I have seen two or three times.

Another cause of mild, but sometimes severe, though easily manageable, inflammation of the testicle, is that arising from congestion of semen in the seminal tubes; which is of very frequent occurrence in lads soon after puberty. First one testicle is attacked with swelling, tenderness, and pain, which speedily subsides on taking a purge, and keeping quiet for a few days; but, in the course of four or five weeks, the other testicle is, in like manner, attacked. And when it gets well, the first affected is again attacked. This will go on for three or four years, to the patient's great inconvenience; but no danger is to be apprehended from it.—J. F. S.]

171. The inflammation of the testicle generally soon becomes acute. The testicle swells considerably, and the swelling is further increased by exudation into the cavity of the vaginal tunic; the skin of the purse is

expanded, reddened, and very painful, not unfrequently accompanied with fever, pain in the belly, disposition to vomit, with great weariness (1).

The usual termination of this inflammation is resolution (2). Dropsy of the vaginal tunic often remains if the inflammation be improperly treated, or if it continue in a less degree for a long time (3).

Suppuration is to be feared if in active inflammation the pain be throbbing. The skin then rises and thins at different parts; it bursts, the pus is discharged, and oftentimes the convoluted vessels of the testicle project from the opening of the abscess, like grayish-white flocculent bodies, which draw out when pulled, so that in the end the albugineous tunic remains empty (4).

Hardening is, on account of the peculiar condition of the testicle, no uncommon termination, specially if the treatment have not been exactly suitable, and scrofulous or gouty disposition be superadded. The bulk of the testicle is often distinctly increased by the hardening. Sometimes it confines itself merely to the epididymis, sometimes the whole testicle, and even a large or small part of the spermatic cord, is hardened (5).

Gangrene is a very rare termination, and only from improper treatment.

[(1) Astley Cooper observes:—"The first symptom of this disease, when it arises from sympathy with the urethra, is an irritation of the membranous or prostatic portion of their canal, as if some drops of urine still remained in the beginning of the urethra, and this is succeeded by a tenderness in the spermatic cord at the abdominal ring, and by swelling and pain in the epididymis. The testicle next swells. * * * The pain is obtuse, and more difficult to bear than that which is more acute, and it resembles the suffering which is produced by squeezing the testicle; and, indeed arises from the same cause, for the glandular structure of the testis swells, whilst the *tunica albuginea*, being tendinous and consequently inelastic, does not yield to the swelling from within, but resists its increase and presses upon the sensitive internal structure of the testicle, producing the dull, heavy, and aching pain of which the patient complains. The pain and swelling extend along the spermatic cord into the inguinal canal, producing great uneasiness in the groin and in the spinous process of the ilium, the hip, and the inner part of the thigh on the affected side, and at length fixes itself more particularly in the loin; and this arises from the renal and lumbar spermatic nerves having their principal origin from the renal and lumbar nerves. * * * The epididymis swells more in proportion than the testis, owing to its covering being less compact, and it remains longer swollen. Its two extremities, i. e. the *globus major* and *minor* are more affected than its body, and the swelling of the former is generally very perceptible before the spermatic cord." (pp. 8–10.)

Sometimes, though not very frequently, (for I have never observed it,) inflammation of the testicle, consequent on gonorrhœa, is immediately preceded by great irritation of the brain, which subsides on, or soon after, the appearance of the swelling. I am indebted to my intelligent friend Sams, of Lee, for the following

Case.—A. B., aged 19 years, of strumous constitution, had gonorrhœa for six weeks, and, after the usual treatment with purgatives, nitrous æther, and copaiba, the discharge had nearly ceased for two or three days, when he was attacked with violent febrile excitement, very quick pulse, and delirium, which continued forty-eight hours, towards the latter part of which the testicle began to swell, and, as the size increased, the head symptoms diminished and subsided. Leeches and other suitable treatment having been employed, the swelling of the testicle declined, and the gonorrhœa returned, but gradually diminished, till there was not more than six or eight drops of discharge a day. He then left the house, and took a walk, but soon had a recurrence of the febrile attack and head symptoms, which, however, went off again as the testicle again swelled, and that also subsided on the reappearance of the discharge from the urethra.—J. F. S.

(2) In general, as the inflammation of the testicle subsides, if the gonorrhœa had stopped, it reappears. Hence some surgeons have proposed its restoration, to cure orchitis.

(3) Adhesion and thickening of the *tunica vaginalis* is also a consequence of inflammation, and Astley Cooper observes that, "on examining the testicles which have felt

harder than usual, that one surface of the *tunica vaginalis* was glued to the other, in some cases partially, and in others entirely." (p. 21.)

(4) Suppuration is but rare when the inflammation of the testicle is sympathetic; thus forming one of the instances of the law on this point, recognised by JOHN HUNTER, and already adverted to in speaking of sympathetic bubo (*par* 160, *note*.) And, indeed, generally suppuration following inflammation of the testicle, from any cause, is not frequent. In these cases "the *tunica albuginea*," says ASTLEY COOPER, "like other tendinous structures possessing few absorbent vessels, does not readily give way to the pressure of the abscess; and it is a long time before it discharges itself, even after the matter can be distinguished by fluctuation. It generally breaks at several apertures, and sinuses follow, which are very difficult to heal, for they issue a seminal as well as a purulent discharge." (p. 12.)

Not unfrequently, after the bursting of an abscess in the testicle, a fungus shoots up, which often exceeds the size of the testicle. It is not painful and but little sensible; neither is it malignant, nor likely to become so, but it often grows very pertinaciously, and requires removal to get rid of its inconvenience.

The constitutional excitement is often very great, setting in with nausea, and followed by hot skin, furred tongue, quick pulse, and constipated bowels, and sometimes even with severe rigors.

It is scarcely possible to confuse orchitis with any other disease, on account of its ordinarily slow progress, and from the epididymis and the body of the testicle being, in general, readily discernible from each other, although much swollen. But SAMUEL COOPER has mentioned a case in which on the fifth day there was so much pain in the belly, accompanied with incessant vomiting, great constipation, and high constitutional disturbance, that it led to a presumption of a rupture, from which, however, it was distinguished by the want of particular protrusion at the ring, by absence of tension of the belly, to one side of which alone the pain was confined.

When swelling of the testicle arises from blows, it comes on very quickly, and doubtless depends on the bursting of some vessel or vessels in the testicle; and it may be complicated with hæmatocele or effusion of blood into the vaginal tunic.

"Wasting of the testicles," says ASTLEY COOPER, "is another effect of inflammation in this organ; and this absorption takes place more frequently at the age of puberty than at any other time;" generally follows inflammation from a blow; sometimes, when it arises spontaneously, and rarely after gonorrhœa, "it begins to be absorbed as the swelling subsides; but the absorption does not stop at the natural size of the part, but proceeds until the whole of the glandular structure of the organ is absorbed, leaving the *tunica vaginalis* adhering to the *tunica albuginea* and the *septa* within the latter; but the whole substance which remains is not larger than the extremity of the finger, and it feels a firm and very solid body." (pp. 23, 24.) Probably the tube of the *vas deferens* is obliterated, as its functions cease; for, in a preparation we have in St. Thomas's Museum, of a wasted testicle, the quicksilver would not descend to within an inch of the testicle.—J. F. S.

(5) ASTLEY COOPER says, that the globus major "is more frequently diseased than any other part of the testis or epididymis," an observation the correctness of which experience fully proves; and he might have added, that it is also of longer endurance, and more difficult to get rid of. "But," he observes, "the result is less important here than in other parts, because some of the *vasa efferentia* and *coni vasculosi* still carry the semen from the testicle to the epididymis. When the hardening is in the upper part of the epididymis, adhesive matter is effused into the cellular membrane, between the *coni vasculosi*, at their termination in the epididymis; and sometimes a sac, containing a mucilaginous fluid, is found at that part. The *coni vasculosi*, under this state of disease, are thickened, hardened, and of a dark brown colour." (p. 22.)]

172. The *Cure* of inflammation of the testicle is directed by its cause and degree. If consequent on gonorrhœa, still in its commencement, and connected with no great swelling, the patient must keep quiet, support the testicle, apply cold lotions of lead wash, lay softening bread-poultices upon the penis, and take a cooling purge. Cold applications, however, which are only to be used at the beginning when the swelling is small, frequently cannot be borne, in which case soothing fomentations and poultices are to be preferred. In greater inflammation, in robust persons, blood must be taken away or leeches applied in sufficient quantity

on the perinæum and inside of the thigh, and warm softening bread poultice applied on the swelling. If, after this treatment, although the inflammation is reduced, great pain still continue, opium with nitre or calomel must be given, opium clysters administered, and narcotic poultices applied. When the tension has diminished, lead wash may be added to the poultices. After the resolution of the inflammation, if the swelling of the testicle still remain for a long time, it must be supported by a suspensory bandage, and mercury with camphor rubbed in. According to Delpech's experience, the above-mentioned treatment of gonorrhœa, combined with cubebs, is sufficient to get rid of the inflammation of the testicle accompanying it.

[The general practice in swelling of the testicle is to adopt the antiphlogistic treatment, which practice I formerly pursued, giving, after a dose of rhubarb and calomel, either a dram of sulphate of magnesia three or four times a day, or tartarized antimony sufficient to produce nausea; and sometimes giving mercury internally, and using friction of mercurial ointment and camphor on the testicle till the mouth became affected. If the inflammation were very severe, cupping on the loins was employed, or local bleeding by leeches, or by opening two or three veins in the purse, and withdrawing three or four ounces of blood, and afterwards a warm bread poultice was applied. When the inflammation was subdued by these means, if the testicle still remained hard, as generally happened when no mercury had been used, then either mercurial friction or binding the testicle up in mercurial plaster was resorted to. Cold washes I never employed, nor have I any experience in the use of cubebs, as recommended by Delpech. I rarely now follow either of these plans, but prefer the use of compressing straps of adhesive or soap plaster, on Fricke's principle. (*pars.* 176, 7.)—J. F. S.]

173. If the inflammation run on to suppuration and an abscess be formed, this must be opened and treated in the usual manner. The whitish-gray *flocculi*, which lie in the opening of the abscess, must be left alone; they often become covered with granulations and are united with the opening. If the suppuration cannot be restrained and the testicle pass into disorganization, its removal is called for.

[When a fungus has sprouted from the aperture by which the pus has been discharged, it should be treated at first by brushing over with nitrate of silver, or solution of sulphate of copper, and then compressing it with circular strips of adhesive plaster. But, if this practice do not succeed, it may be cut off with a knife to the level of the skin, and the edges of the wound having been pared, to set the skin loose, it may be brought together, and treated as a simple incised wound, which usually effects the cure. Occasionally, however, though rarely, little abscesses are cut through in removing the fungus: as these descend more or less deeply into the body of the testicle, it is better to remove the entire gland at once; a case of which kind I have lately operated on. But under ordinary circumstances castration is neither required nor to be practised.—J. F. S.]

174. Hardening is for the most part confined to the epididymis, generally gives scarcely any pain, and may continue throughout life. In diseased dispositions and dyscracy, or from injuries which set up inflammation afresh, swelling of the spermatic cord, collections of water in the vaginal tunic, sarcomatous and cancerous hardenings are produced. The dispersion of the hardening may with proper care be attempted by the general remedies (*par.* 68) already mentioned, during which the testicles must be supported in a suspender. If the pain in the testicle become more severe and shooting, if the swelling be uneven and knobby, its extirpation is the only mode of preventing its passage into cancerous destruction. Not unfrequently, as a symptom of general venereal disease, a hard swelling of the testicle is slowly produced, which may generally be dispersed by a regular mercurial treatment or by the proper exhibition of cubebs (*par.* 167.) The hardening of the testicle from one gonorrhœa is not unfrequently dispersed by a fresh gonorrhœa; hence the proposition of passing bougies smeared

with red precipitate ointment, (not with gonorrhœal mucus,) to excite fresh inflammation of the urethra.

175. Inflammation of the testicle following mechanical violence or catching cold, is to be treated as above prescribed, (*par.* 172,) without reference to the inflammation of the urethra.

176. As in diffuse inflammation of the cellular tissue, its resolution has been attempted by continued pressure, (*par.* 91,) so Fricke (*a*) has recommended compression as the most effectual remedy in all cases of inflammatory swelling of the testicle, from whatever cause. The degree and duration of the inflammation are here of no consequence; but, if general illness, (for instance, actual gastric disease, be connected with it,) this treatment must be given up. Vascular reaction does not contraindicate compression, nor yet buboes nor sores. After compression the pain is at first frequently increased, and, if the pressure be too great, it is very severe; it does not, however, continue long, and, speedily, often within a quarter of an hour, the patient is free from pain. Frequently after compression gastric symptoms, as disposition to vomit, bitter taste and so on, occur, the compression must then be removed and a vomit given. If the pain continue after the compression, there must be some general disease causing this want of success. In severe traumatic *orchitis*, leeches first, and poultices for two or three days, must be used.

[I have, for some time past, adopted Fricke's practice of compression, with the greatest success, and rarely now use any other. I have occasionally heard it objected, that it produces so much pain, the patient cannot bear it, and that its removal is absolutely required. My experience is directly contrary to this assertion. I have had but two cases in which the compression was unbearable; whilst, on the other hand, all pain generally subsides in a quarter or half an hour. I feel, therefore, pretty certain, that the fault must rest with the mode in which the compression is applied, and not on the remedy itself. I think it far preferable to the old method of purging, or of making the mouth sore, which I, in common with many others, heretofore generally adopted, and therefore strongly recommend its employment, as an easy and speedy cure.

Very often under this treatment, as under the antiphlogistic, when the inflammation subsides, the discharge from the urethra returns. Sometimes, but not always, hardness of the epididymis remains for a long while; but I do not think it of material consequence.—J. F. S.]

177. For compressing the testicle, strips of new linen or sheeting, cut in the direction of the threads, should be used, a full thumb broad and an ell long, and spread by a machine with good sticking but not too irritating adhesive plaster. The patient, in slight cases, may place himself before his medical attendant, leaning against the wall, in other cases he must lie on the edge of the bed or sofa that the purse may freely hang down. If the hair on the pubes be too long, it must be shaved. The practitioner takes the testicle in one hand, separating it from the sound one, while with the other he somewhat stretches the skin of the scrotum. The spermatic cord is also in like manner to be separated. If the testicle be very much swollen an assistant must hold it, otherwise it is sufficient for the patient himself to separate the healthy from the diseased testicle. The first strip of sticking plaster is to be applied upon the isolated spermatic cord an inch above the testicle, the end of the strip is to be held with the thumb whilst a circular band is applied round the cord. In the same manner a second strip is to be put on, which should partially cover the first. This act of compression must be carefully made, the sticking

---

(*a*) Ueber die Behandlung der Hodenentzündung durch compression; in Hamburger Zeitschrift für die gesammte Medicin, vol. i. part i.

plaster must closely envelop the cord, so that the testicle, especially if compressed at its lower end, cannot slip up through the loop which has been made towards the abdominal ring. The application of the sticking plaster is to be continued downwards to the bottom of the testicle in such way that each new turn overlaps one third of the breadth of the preceding one. Having reached the part of the swelling which has the largest girth, and where it gradually diminishes towards the base, the sticking plaster must no longer be applied circularly; the left hand must now grasp the part where the first strip was applied, and apply other strips, that, beginning from the upper part, they may be stretched in the long diameter of the testicle over the bottom and the other end attached behind. So many strips are to be applied in this direction that every part of the purse is covered, and the testicle enclosed and compressed in every direction. The application over the testicle must not be too tight. If both testicles are swollen, the compression must be applied as above described on one; there will not, however, be sufficient room for the circular straps to be applied separately on the other; they must, therefore, be so arranged that the previously compressed testicle should be enclosed with the other, and that thus strips of plaster should be carried around both testicles, the former serving as the point of support for the other. The strips from before to behind should be applied as already stated.

[I do not either approve or practise this mode of applying the plaster, but always commence from the bottom of the testicle, and pass upwards. It is rather more difficult; but if the skin of the purse be made tight over the testicle, as in operating for hydrocele, there is little awkwardness in applying the first few strips of plaster, and the rest follow with ease. Also as regards binding up the second testicle, if swollen, against that first compressed, I have not found much need to do so. The plasters will not fit very well at the first application; but, generally at the second, the pressure yields quite sufficiently for the perfect adjustment of the compression on each single testicle.—J. F. S.]

178. The patient can generally leave his bed immediately after the plaster has been put on; if the inflammation be not very severe, or, if just commencing, he may even go about. The reapplication of the bandage, if once be insufficient, should only be made when the sticking plaster has become so loose that the scissors can be introduced under it to divide it. If in patients with irritable skin the plaster causes excoriations, little notches must be made, and GOULARD's wash applied over it.

[I have not found once nor twice sufficient for the reapplication of the compressing straps, but they need putting on afresh for several days. The diminution of the bulk of the testicle at each visit, till it reverts to its natural size, is often very remarkable.—J. F. S.]

[*Metastasis of Gonorrhœa and Inflamed Testicle to the Brain.*

In speaking of Mumps it was mentioned that metastasis of that disorder sometimes occurred to the testicle or breast: and, I think, I am able to show that from gonorrhœa, and swelled testicle consequent on it, a metastasis may also take place to the brain, as in the following

CASE.—G. C., aged 31 years, a gardener, of healthy appearance, with a slight drawing up of the left corner of his mouth, was admitted into St. Thomas's, under my care, *Oct.* 22, 1844. He states, that during infancy he was subject to fits, whence ensued the drawing up of his mouth, as at present existing; but his health has been good up to two years since, when, whilst walking, he suddenly became giddy and insensible, and was told he was convulsed. He remembers he had then violent head-ache, and that he was cupped, blistered, and bled repeatedly, and under medical treatment for two months or more. Last June he had another attack of severe head-ache, and was relieved by cupping and purging; but he has since been subject to swimming in the head, with dread of falling.

About six weeks since he was attacked with a thick glutinous discharge from the urethra, which he cannot ascribe to a recent cause, not having had any connexion for a long while. The discharge continued pretty copious till within the last three days, when it diminished considerably, and the left testicle began to swell: it is now twice as large as natural, flattened, and very painful. I ordered him a dose of rhubarb and calomel, and the testicle to be strapped.

Oct. 26. The size of the testicle much reduced, and the strapping therefore to be reapplied. The discharge has rather increased.

Oct. 29. In consequence of the continued increase of the discharge, an injection of nitrate of silver, three grains to a pint of water, was ordered, by the use of which, in the course of a few days, the discharge was lessened.

Nov. 9. The testicle has returned to its natural size. He is complaining of headache, and feels swimming and giddiness.

Nov. 12. Has violent pain across the temples; pupils dilated and fixed, and vision dimmed; hearing very acute and he is much disturbed by the slightest noise; pulse 80, full and very incompressible; tongue white; bowels soluble; urethral discharge lessened. ℞ *pil. col. c. cal.* gr.x. *stat., c. c. ad* ℥xij. *nuchæ et empl. lytt. postea adhib.*

Nov. 14. Has not slept for the last two nights; mouth more drawn up since yesterday than heretofore; hearing very acute; vision more dim. The shooting pain across the forehead is more severe, and comes on every ten minutes in paroxysms; is perfectly sensible, and answers without hesitation; bowels confined. Discharge from the urethra *entirely stopped.* ℞ *pulv. rhei. c. hydr.* ℈j.; *hirud.* xij. *temp.*

Nov. 15. Mouth more drawn; head symptoms as last reported; pulse 108, softer; bowels open: complains of nausea. ℞ *hydr. chlorid.* gr.ij., *ant. potass. tart.* gr.½. 6*tis.*; *hirud.* xij. *temp.*

Nov. 17. This afternoon he had an attack of violent pain in the belly, with tenderness on pressure; pulse 108 and feeble. He was put in the hot bath, and a mustard poultice applied to the belly, by which he was relieved. But in the evening he had violent spasmodic pain, and it was found his bowels had not been relieved for the last three days. ℞ *ol. ricini* ℥ss., *tinct. opii* ♏xx. *stat.* This relieved him of the pain in the belly in the course of an hour or two. The head symptoms still continuing, a blister was applied to the nape of the neck.

Nov. 18. Had no sleep last night, but was quiet; and has had this morning about half an hour's sleep, the first he has had (according to his own account) since the 12th ult. Pain in the head violent as ever; pupils fixed and eyes vacant; pulse 108, feeble, sharp, but soft; tongue brownish; bowels open.

Nov. 19. Still most violent head-ache, and complains of pain in the belly. Put into a slipper bath immediately, which much relieved him; his head to be shaved, and cold lotions to be applied. ℞ *tinct. rhei* ʒiv., *tinct. op.* ♏xx. *ex aquâ menthæ piper.*

Nov. 20. His head aches much less: the pupils contract sluggishly on the application of light; pulse 108, feeble; bowels freely opened.

Nov. 21. Slept well last night; has less head-ache, but the pupils still continue sluggish; the countenance is less anxious; pulse 84, softer.

Nov. 22. His mouth having now began to be affected with the mercury, and his symptoms being improved, the pill was direeted to be taken at night only.

Nov. 29. Has continued mending; the head-ache has ceased, and his mouth has now reverted to its usual drawing up, the medicine was therefore left off. A gleety discharge from the urethra has re-appeared.

Dec. Left the house quite well. The discharge has gradually subsided without any treatment.—J. F. S.]

179. The proper application of the plaster requires great care; I have observed injurious effects from compression, in the practice abroad, by inattention to this circumstance. The advantages of this mode of treatment are, according to FRICKE's numerous observations, quick subsidence of the pain, a more rapid cure of the disease, simplicity, cheapness, and little want of attendance.

VI.—OF INFLAMMATION OF THE LUMBAR MUSCLES.

180. *Inflammation of the Lumbar Muscles* (*Lumbago*, *Psoitis*, Lat.; *Entzündung der Lendenmuskeln*, Germ.; *Inflammation des Muscles Lombaires*, Fr.) is situated in the *musculus psoas* and *m. quadratus lumborum*, and in the surrounding cellular tissue (1).

It sometimes occurs suddenly; the patient feels pain in the loins; walking becomes troublesome; the thighs can be neither raised nor completely extended without pain. Sometimes it commences gradually, with pricking pain, which, becoming more severe, spreads into the hip and thigh to the knee-joint. Not unfrequently the course of the inflammation is so insidious that it is scarcely noticed, and the disease is first shown by the collection of pus. According to the degree of the inflammation does suppuration occur early or late. The pus collects in the cellular tissue surrounding the *psoas* muscle, descends in its course, and a swelling is produced beneath Poupart's ligament, in the neighbourhood of the rectum, upon the spine, and so on. During these collections of matter, the patient suffers pain in the loins; walking is troublesome, a movement of the pus contained in the swelling is felt on coughing; the swelling is smaller when in the recumbent posture; at first the skin is unchanged. The general symptoms of suppuration, as emaciation, night sweats, hectic fever, and so on, rarely occur when the extent of the abscess is not large. But if, during its increase, the skin covering it inflame and break, pus is discharged at first without smell, but subsequently stinking, and the powers of the patient are quickly exhausted, or the aperture draws together and remains fistulous for a long time.

[(1) It must be distinctly understood that the disease now under consideration, is not that we usually call "Lumbago," which consists of a rheumatic inflammation of the lumbar fascia, but the complaint which we know as "Psoas or Lumbar Abscess;" and, as will be presently seen, it is almost always a secondary disease, a disease *in* the part, and not *of* the part, as Hunter calls such, resulting from affection of the vertebræ, and would be more in place if considered with diseases of joints, under the head "Inflammation of the Vertebral Joints." (*par.* 257 and following.)—J. F. S.

Astley Cooper says of this disease:—"You may know this abscess by the following marks:—in the first place, when you ask the patient whether he has for a long time had continued pains in the loins; if he has psoas abscess, he will reply 'yes; four, five, or six months;' you will find that he has a difficulty in extending the thigh if he puts his legs together, he feels pain and tightness in the groin, and has increased pain in attempting to exert the limb, in consequence of the psoas muscle being then on the stretch." (p. 460.)

Pearson remarks, that "during the progress of suppuration, as there is a remission of the more severe symptoms, the patient often imagines that he is recovering his health; some degree of pain, however, and an inability of duly performing the motion of the parts always remain. He is, sooner or later, alarmed by the appearance of a soft tumor, which arises in one or more of the parts enumerated above. At the first it is rarely accompanied with any discoloration of the integuments or pain, unless it be compressed. When the person stands erect, the tumour becomes more prominent; but its contents recede, either in whole or in part, when he assumes a horizontal posture." He also notices, that "if the contents of the abscess be included in a firm cyst, the long continued pressure of so large a body upon the lumbar vertebræ will sometimes induce a paralysis of the lower extremities." (pp. 97–9.)]

181. The causes of this inflammation may be external violence, severe strains, catching cold, rheumatism, gout, dyscratic affections of all kinds. Caries of the lumbar vertebræ very frequently accompanies lumbar abscess, of which it may be cause or consequence.

[The cause of this disease is held by English surgeons in general to be disease of the vertebræ. This seems to have been first noticed by **Pott**, who, in speaking of the complaint which arises from what is commonly called "strumous or scrofulous indisposition affecting the parts composing the spine," says, that "sometimes it is found in the form of bags or cysts, containing a quantity of stuff of very unequal consistence, partly purulent, partly sanious, and partly a curd-like kind of substance; and not unfrequently entirely of the last. Sometimes, under these bags or cysts, even while they remain whole, the subjacent bones are found to be distempered, that is, deprived of periosteum, and tending to become carious." And then he comes to the disease now considered:—"Sometimes these collections erode the containing membranes, and make their way down by the side of the psoas muscle toward the groin, or by the side of the pelvis behind the great trochanter, or, in some cases, to the outside of the upper part of the thigh." (pp. 467, 8.)

Astley Cooper describes it as "very often nothing more than an abscess, from the disease of the intervertebral substance which I have just spoken of, having its origin in inflammation of the spine and the intervertebral substance. The matter spreads till it reaches the origin of the psoas muscle, which passes into ulceration, and forms a bag, surrounded by a complete ring. The abscess proceeds as far as the tendon of the muscle, by **Poupart's** ligament, and its further progress is restrained by the tendon; when it passes under **Poupart's** ligament, between the femoral vein and the *symphysis pubis*, it has generally attained considerable magnitude, and has the appearance of femoral hernia. * * * If the abscess form on the side of the vertebræ, instead of the fore part, it is termed lumbar abscess instead of psoas." (p. 460.)

Abernethy says:—"Lumbar abscesses in general descend along the psoas muscle, under **Poupart's** ligament;" they "also, in general, are not simple diseases; they arise from and communicate with carious vertebræ; which circumstance is, I believe, the cause of their frequent fatality. The first eight cases that I attended, after I had adopted a new mode of opening them, were simple abscesses, and not arising from disease of the bone, which led me to believe that they were more frequently unconnected with diseased bone than later experience has taught me. The general opinion of Surgeons, in which I entirely concur, is, that lumbar abscesses most frequently arise in consequence of diseases of the vertebræ, and they should certainly all be treated as if such was their origin;" (p. 143.) "as," he afterwards observes, "we cannot know whether the bone be diseased or not." (p. 159.)

Lawrence speaks of "the chronic abscess termed *psoas* or *lumbar abscess*, where, in consequence of the disease of the vertebræ of the lower portion of the back or loins, matter forms around that diseased part, and then descends through the loose cellular membrane covering the muscles along the side of the pelvis into the thigh; it may take a course towards the back, or may go in various directions either within or on the outside of the pelvis." (p. 396.)

Dupuytren says:—"Caries having been once established, the pus remains for a longer or shorter time in the carious spot, in the parts surrounding it, and especially in the cellular tissue. It forms at first a cyst where the pus collects. As the quantity of pus increases the cyst descends; lengthens as it inclines to one or other side of the spinal column, or to both sides at once; the pus makes its way, pushing before it the lower end of the cyst; if it meet with any obstacle it spreads out, but contracts when pressed on by the neighbouring parts, and dilates again when relieved from the pressure. Having arrived beneath the skin, after a more or less lengthy course, the pus projects, and causes a swelling which terminates by forming an abscess. This purulent collection, known by the name of *congestive abscess*, but more properly called *symptomatic abscess*, is a very serious disease, and generally considered fatal." (pp. 136, 7.)

The disease may and frequently does arise from external violence, blows, strains, or the like; but its commencement is in the spine, whence it is propagated to the muscles, which, however, are in fact only absorbed to form a route for the matter produced by the diseased vertebræ to escape.]

Inflammation and suppuration in the psoas muscle, or in the lumbar mass of muscles, without disease of the spine, is rare, and more especially in the former. Of the nineteen cases given by Abernethy, only two are mentioned in which there was no actual disease of spine.—J. F. S.]

[181*. Psoas abscess, when protruding below Poupart's ligament, may, on account of having the same seat as femoral hernia, be mistaken for that disease, especially as it dilates on coughing, and to a certain degree returns into the belly when the patient lies down. But it is generally of larger size, of greater breadth than femoral rupture, and the fingers cannot be at all thrust behind it, as they can be partially behind the hernial sac. The principle distinction, however, is the long continuance of pain in the loins previous to its appearance, and which, indeed, still continues: and the pain produced by attempting to extend the thigh backwards upon the pelvis, and which can only be effected to a limited extent. When the abscess appears in the loins there is no difficulty in determining its character by its history and by its dilatation on coughing. Pulsation may sometimes be communicated to it from the neighbouring large vessels, and under such circumstances it has been mistaken for aneurism.—J. F. S.

John Pearson well observes:—"The situation of the external abscess is not uniform; most commonly it is at some distance from the original seat of the disease; nor is the point at which it projects forward to be considered as forming a portion of the abscess. The fluctuation of the matter may therefore be mos tpalpable about the loins, or at the hip, in the groin, or near the rectum, and sometimes it points towards the lower part of the thigh, in the direction of the large blood vessels." (pp. 96, 7.) "As the purulent matter is situated behind the peritoneum, and the erect position of the body is favourable to its progression downwards, we do not often meet with instances where it is effused into the cavity of the abdomen." (pp. 98, 9.)

Samuel Cooper (*a*) mentions a remarkable case of lumbar abscess, under the care of Ramsden, in which "the tumour extended, from the ilium and sacrum below, as high as the ribs; its diameter, from behind forwards, might be about six or eight inches; it was attended with so strong a pulsation, corresponding with that of the arteries, that it was considered to be a case of aneurism of the aorta. After some weeks, as the tumour increased in size, the throbbing of the whole swelling gradually became fainter and fainter, and at length could not be felt at all. The tumour was nearly on the point of bursting, and Ramsden, suspecting that it was an abscess, determined to make a small puncture in it; and a large quantity of pus was evacuated at intervals." (p. 944.)]

182. The dispersion of the inflammation of the lumbar muscles would be in most instances possible, were not the symptoms often at first so slight as to be usually neglected. The *Cure* is directed by the degree of the inflammation and its causes. In severe inflammation the antiphlogistic treatment is properly adopted, blood-letting, the application of leeches or cupping-glasses. As the inflammation diminishes, the resolution is to be encouraged by volatile ointments and perpetual blisters. If the cause be rheumatism or gout, and the inflammation be insidious, solution of acetate of ammonia in infusion of elder flowers, antimonial wine in small doses, Dover's powder, camphor and the like, may be given; but especially warm baths, rubbing in volatile ointments, blisters, and issues, are to be used.

(*a*) Surgical Dictionary,—Article, *Lumbar Abscess.*

[The reason assigned by Chelius for the neglect of the primary symptoms of this disease is hardly carried far enough, as, in reality, the attack comes on so slowly and insidiously that the patient is scarcely aware of having anything more than slight rheumatic or "growing pains," as young people call them, till some trifling occurrence brings him to a stand-still, and the serious character of his disorder is almost accidentally discovered, often, indeed, not before it has proceeded to suppuration.—J. F. S.]

183. When the inflammation terminates in suppuration, and swellings are formed by the descent of the pus, such abscesses, even when they have obtained a considerable size, may, in some cases, although rarely, be dispersed, by perpetual blisters or issues on the loins, by general treatment which puts the abdominal functions in order and strengthens the patient's powers (1). But if, under this treatment, the abscess increase, it must be opened with a lancet, which should be introduced obliquely (2). The pus must be discharged, as far as possible, in an unbroken stream. The wound is to be carefully closed with sticking plaster, a compress is to be laid over it, the patient kept quiet, and the above-mentioned treatment employed. The wound usually closes in a few days; but the pus most commonly recollects, though in less quantity than at first. If the swelling again rise sufficiently high, it must be again emptied as before, and this must be repeated as often as the abscess is reformed. If the abscess be originally of no great size, or diminished by repeated punctures, it is often best to treat it as a common abscess, to open it freely, and simply apply a poultice; at the same time, however, supporting the powers by tonic remedies, and by a proper dietetic regimen.

[(1) Dupuytren observes, that "these abscesses remain sometimes in the same state for years, and without causing any symptoms; the pus is gradually absorbed and no trace of them remains. At other times, after a greater or less interval, the skin covering them inflames, bursts, and gives issue to the pus, which drains away and is not reproduced. In other circumstances, the pus, having remained for a longer or shorter time, is converted into an adipocerous matter: chemical experiments have proved, indeed, that such is the nature of the substance sometimes met with in abscesses of this kind." (p. 138.)

Astley Cooper has made the following observation in regard to the treatment of this disease:—"You must allow the abscess to take its course; very little can be done in this disease until it has acquired considerable magnitude." (p. 460.) This recommendation is very unsatisfactory; for the treatment should be commenced so soon as the existence of the disease can be ascertained with any certainty, so far, at least, as the use of counter irritants is concerned; for I cannot agree with Cooper that "little can be done to prevent its progress when once formed, and I do not know that any advantage is to be derived from counter irritation." (p. 461.) I feel sure, on the contrary, that much may be done, and, believing that caries of the vertebræ is always the origin of the disease, the treatment which it requires is that which at the onset is necessary for lumbar or psoas abscess, and which, indeed, must be persevered in, even after the abscess has either burst or been punctured; I mean the use of issues.—J. F. S.

Various expedients have been proposed for exciting the absorbents to take up the pus. "The elder Cline (*a*) once gave digitalis to a very considerable extent to a boy of fourteen or fifteen years old; the abscess diminished for a little time, but when the digitalis was given up, in consequence of its influence on the general health, the disease returned." (p. 461.) Abernethy has recommended the application of repeated blisters or of open blisters upon the swelling, and has given two cases under this treatment in which the pus was absorbed. I have not had any personal experience on this point, and cannot, therefore, say anything about it. The same distinguished surgeon has also advocated the use of electricity; but, as in all the cases in which he employed it, other remedies were also used, it is not possible to determine what benefit was attained by it. The exhibition of emetics, to which he also resorted, was under the same circumstances, and, therefore, much cannot be decidedly attributed to them.

Issues are most important aids in the successful treatment of psoas or lumbar abscess, either whilst the abscess remains unopen, or after an aperture in it has been self-formed or made artificially, by which the pus has escaped, and from which it long

(*a*) As stated by Astley Cooper.

continues to be discharged. I do not know any circumstance under which their employment should be withheld. The issue should not be made on the same side of the spine as that where the abscess is, if presenting in the loins, but on the other side, and opposite the outer margin of the *m. quadratus lumborum.* And, if there be abscess in both lumbar regions, the issues should be put in above and below them. But, if the swelling present in the top of the thigh, as in the psoas abscess specially so called, it may then be made on the same side, or, indeed, on both sides issues may be introduced. The issue should never be made upon the ridge of the spine, as, on account of the nearness of the spinous processes to the skin, the periosteum and ligaments covering their tips may be involved in the slough, and the processes themselves become necrotic. Neither should it be made over or upon the abscess itself, as the separation of the slough will open its cavity. Large issues I do not think advisable: a slough as large as a sixpence, made with caustic potash, will, when thrown off, leave a wound as big as a shilling, which is large enough to hold three or four glass beads, and amply sufficient, as with but little attention the issues can be kept open for a considerable time, and, when they seem disposed to heal, their surface must be smeared with the caustic potash sufficiently to produce a fresh slough, and, on its separation, the peas are to be again introduced. The intention of the issues is to divert the diseased action going on in the vertebral column, which is generally the cause of psoas or lumbar abscess, as already mentioned, and is a practice which I have found eminently successful.—J. F. S.

(2) Much difference of opinion still exists among surgeons as to the propriety of waiting the self-evacuation of these abscesses, or of puncturing and emptying them either entirely or partially.

Abernethy asks, when the abscess " protrudes the integuments, that they, from distension, become irritated; that their temperature is slightly augmented; what are we then to do? Are we to wait till evident signs of inflammation appear? I think not. I would relieve them from distension, by emptying the abscess through a wound made by an abscess lancet. I would open the abscess for a reason which appears paradoxical on its first proposal, which is that it may be kept closed. We can empty a cavity, and by healing the wound keep it afterwards shut, and no inflammation ensues. If nature opens the cavity by ulceration, the opening is permanent and the inflammation consequent must be endured." (p. 153.)

The practice of puncturing large abscesses with a trocar, seems to have been first advised by Deckers, in 1696; he left the canula in the cavity stopped with a cork, and let out the matter at intervals. The same proceeding was also adopted by Benjamin Bell. Tapping these abscesses with a small trocar was also recommended by Crowther, who always introduced it at the same spot. He thought that the aperture so made did not ulcerate, nor allow the matter to escape after being dressed. In addition to drawing off the pus with a trocar, Latta (*a*) advises, that after this is effected, the end of the canula, which had been introduced at the bottom, should be pressed gently up to the top of the abscess, the trocar introduced into it and thrust through the skin, and then, being withdrawn, a skein of silk to be passed through the canula, which is also to be removed, and thus a seton formed. (p. 36.) The introduction of the seton is, I should consider, a very dangerous experiment, as likely to excite inflammation, always too much to be dreaded, in a part too prone to run into that condition. I have never pursued this practice, nor, for the reason just mentioned, should I be disposed to do so. And, as to puncturing with the trocar, I do not see any advantage to be obtained from it, and certainly cannot believe the wound would heal more speedily than a simple puncture with a lancet.—J. F. S.

Abernethy's peculiar treatment consisted in puncturing with " an abscess lancet introduced with very little obliquity so far that the wound of the cyst of the abscess should be half an inch in length, and that of the integuments, of course, a little longer. A wound of that size is generally sufficient to give discharge to the solid flakes which will occasionally block up the opening without much poking. It is necessary that the flow of matter should be uninterrupted, so that no air should gain admittance; it is, therefore, right to make pressure on the abscess, in proportion as it is emptied. The abscess where it presents itself is emptied before that part of it in the loins is completely so. The surgeon should then press the sides of the wound together with his finger and thumb, so as to prevent the ingress of air, and desire the patient to cough repeatedly, which will impel the matter from the internal part of the abscess into that which is punctured. When the abscess is emptied as much as possible, the wound should be attentively wiped, and the edges placed in exact contact, and retained in that state by strips of plaster." (p. 154.) A compress is then put on, but no bandage; the patient is

---

(*a*) Practical System of Surgery, vol. i.

to lie perfectly quiet, and the wound, being dressed every second day, "generally united by adhesion, though sometimes otherwise, for it may discharge a little, and yet unite firmly. The abscess thus treated is as free from inflammation as it was before it was punctured. The abscess will, however, fill again, and that sometimes even rapidly. In the first cases which I attended, I punctured pretty regularly after the expiration of a fortnight, and I found in general that the abscess contained about one-third less of fluid. * * * After having discharged the contents of the abscess three or four times, I found that it was not necessary, nor, indeed, easily practicable to puncture it at the end of the fortnight, because it was so little filled and prominent." (pp. 155, 6.)

ASTLEY COOPER supports ABERNETHY'S mode of treatment. He says:—"Let the abscess proceed until you observe a redness or blush of the skin, and then adopt Mr. ABERNETHY'S plan of making a valvular opening into the part, so as to discharge the matter, and close the wound almost immediately. The danger does not arise from the quantity of matter accumulated, but from the irritation produced by the attempts of nature to close the abscess and fill the cavity by the process of adhesion. Four days after the abscess is opened violent symptoms of constitutional irritation are apt to come on, such as great depression of strength, loss of appetite, and the patient is soon reduced to the lowest extremity. It is extremely desirable to prevent the occurrence of these symptoms, and the plan of Mr. ABERNETHY is the best that has ever been suggested by any Surgeon with a view of preventing them." (p. 461.)

LAWRENCE also advocates ABERNETHY'S practice, as it "gets rid of the continuance of an abscess of this kind without incurring the risk of the inconvenience" which arises when, "as in opening a phlegmonous abscess, an incision is made and the matter let run out, and then applying a poultice over it, the access of air into the abscess produces decomposition of the pus which it contains, the matter becomes fetid, the surface of the abscess is inflamed, and the secretion from its sides becomes exceedingly altered, thin, and stinking, extremely irritating to the portion which is in contact with it. The inflamed surface of the abscess is a source of sympathetic disturbance in other parts in the alimentary canal or in the vascular system, and thus arises fever of a different kind." (p. 396.)

Other writers, as KIRKLAND, prefer "the tumour being suffered to break of itself, and its contents to drain gently off, through a very small aperture, which prevents the free ingress of air and violent symptoms; for, when a large tumour of this sort forms on the inside of the thigh, and breaks in a large opening, in such a manner that the air has already passage, we frequently see a violent colliquative fever succeed, that closes the scene in a very short time. But, though small openings should be obtained if possible, they too seldom secure the patient." (p. 199.)

JOHN PEARSON observes on this point:—"Some of the older Surgeons, and the French Surgeons (of his time) in general, advise a free opening to be made, or the introduction of a seton. It hath been thought more advisable, by other practitioners, to permit the abscess to burst spontaneously. Several of the modern Surgeons recommend a very small aperture to be made, and the ulcer to be treated in a very gentle manner. My own experience is in favour of the last mode of treatment, and I have been so happy as to see it followed by a perfect cure of the disease." (p. 103.)

DUPUYTREN "considers it dangerous to open symptomatic abscesses, resulting from caries of the spine, which has yielded to treatment. So to proceed is to re-excite the principal malady, and to lose all the benefit of long and active treatment. He, therefore, recommends giving up these abscesses to the mere efforts of nature; and he follows the same practice even when all remedies have been unavailing to cure the caries." (p. 139.)

The practice I have pursued, which has been for many years past commonly followed at St. Thomas's Hospital, has been either to permit the abscess to break of itself, or only to puncture it when the skin has so reddened and thinned at one point that there is no chance of its bursting being avoided. The puncture should not be a large one, nor do I think making it valvular is of any consequence, as I make no effort to produce its union. It should be of sufficient size to permit the escape of the pus, which should flow out, if it may be so said, at the pleasure of the abscess, which should, on no account, be squeezed or kneaded, to empty its cavity. If thus left to itself the pus flows slowly and the sides of the abscess gradually fall together, though without at once uniting, and accommodate themselves to their new condition, so that ultimately the original abscess becomes only a more or less capacious sinuous cavity, which, if the disease originate in the spine, gives vent to the pus there formed, and may itself also, for a longer or shorter time, furnish the discharge. I have not generally observed the hectic symptoms which by some Surgeons are described as almost certainly occurring when large abscesses, bursting or being opened, at once empty themselves; and I apprehend that when the sac inflames and hectic fever comes on, the cause is rather in the irritable state of the constitution than in the emptying of the abscess. I am not prepared to say, nor would I advise a large puncture and the immediate emptying of the abscess; but, from repeated observation of the practice of others, corresponding to my own above described, viz., the gradual evacuation, either by bursting or by a moderately large puncture, I am convinced that this plan of proceedings is the best.—J. F. S.

The issues are to be still kept up, even after the puncture has been made, for the purpose of diverting the original disease, as already mentioned; and this practice is in accordance with **Abernethy**'s recommendation, that "an issue should be made in the loins, which is likely to be beneficial by its counter-irritation, even when the abscess is not connected with diseased bone; but, when it is, then an issue will be more serviceable and necessary." (p. 151.)

As regards injecting the sinuous cavities into which, after a time, these abscesses are converted, **Pearson** states, that "some of the older writers forbid the use of injections in the lumbar abscess; but their reasons seem to be founded upon mistaken ideas of the true situation of the disease. Solutions of copper, vitriol, or even tepid sea water may sometimes be applied in this way with considerable advantage." (pp. 103, 4.) **Astley Cooper** also says, he "has seen benefit from injecting the abscess, (I presume when it has become fistulous,—J. F. S.): the injection usually employed is the sulphate of zinc or alumen; it promotes the adhesive process in the interior of the abscess, glues its sides together, and lessens the purulent secretion." (p. 461.) **Dupuytren** states "that cauterization may be employed advantageously; but the actual cautery must be straight and exactly run through the canal. In other cases it may be convenient to have recourse to injections of nitrate of silver, or of nitric acid, largely diluted with water, taking care that these liquids do not escape in their course. For these injections he employs twenty or thirty grains, or a drachm of nitrate of silver to a pint of distilled water, and injects it with a siphonous syringe." (p. 148.)

184. There is danger when the cavity of the abscess inflames after the discharge of the pus; and attempts must be made to diminish the inflammation by quiet, by suitable antiphlogistic treatment, and by discharge of the pus. If symptoms of hectic fever are indicated, or the opening of the abscess become fistulous, (the cause of which may be some internal process still going on, such as caries of the lumbar vertebræ or thickening of the walls of the abscess,) the powers of the patient must be supported as much as possible, and, if a general cause can be found out, we must endeavour to counteract it.

[When the cavity of the abscess is inflamed it is known by the great pain caused by slight pressure on the surface, and by the escape of a thin, fetid, frothy matter from the aperture, whether made by ulceration or artificially. It is generally accompanied by the hectic symptoms; but, sometimes, **Abernethy** observes, "both the local and constitutional diseases are of a more purely inflammatory kind;" under which circumstance, the above-mentioned discharge and the hectic symptoms are deficient. Sometimes "the fever is at first inflammatory, then hectical, and, when the local complaint becomes indolent, the general state of the patient's health is no longer affected." And **Abernethy** says, he has "known a considerable space of time elapse between the first bursting of a lumbar abscess and its assuming that morbid state which is so peculiar to those diseases, and which produces a corresponding affection of the system in general." (pp. 221, 2.)

In conclusion, it is right to mention the important observation made by **Pearson**, that, "although the larger arteries have been known to be surrounded with purulent matter for a considerable length of time without suffering any injury, yet this is not universally the case; there have occurred many instances where erosion has taken place, and the person has been suddenly destroyed with hæmorrhage." (pp. 99, 100.) **M'Dowell** (*a*), however, mentions a case in which "ulceration took place in a portion of the ilium adhering to the cyst of the abscess: and the contents of the bowel, after having passed into the abscess, escaped through a fistulous opening near the spine of the ileum. Ulceration also of the external iliac artery followed about an inch and a half above **Poupart**'s ligament, and sudden death resulted from the blood escaping in large quantities into the cavity of the abscess." (pp. 912.)]

185. *Whitlow*, or *Inflammation of the Nail-Joint of the Fingers and Toes*, (*Panaritium*, *Onychia*, *Paronychia*, Lat. ; *Umlauf*, *Wurm*, Germ. ; *Inflammation des Doigts*, *Panaris*, Fr.,) according to its seat and the consequent variations of its severity, usually presents itself in the following four degrees :—

[The following mode of deriving the term whitlow, as given by **Beckett** (*a*), is interesting :—" The old English word *hawe* signifies a swelling of any part. Thus, for instance, a little swelling on the cornea, was anciently called the *hawe in the eye ;* and the swelling that frequently happens on the finger, on one side the nail, was called *whitehawe*, and afterwards *whitflaw* or *whitlow*." (p. 52.)

The division of whitlows employed by **Chelius** was first proposed by **Garengeot**, and is generally followed; but, excepting the first species, which is well marked, I am rather disposed to agree with **Gibson** (*b*), that " these varieties, however, are in a great measure arbitrary; for it is not always in the power of any surgeon to declare from examination of the part, what particular texture is affected." (p. 186.)—J. F. S.]

First. If the inflammation be entirely superficial at the root or side of the nail, the pain is not great; the swelling does not spread beyond the first joint of the finger, but quickly passes to the outpouring of a purulent matter which lies immediately beneath the skin, and assumes a bluish colour; the pain only becomes severe when pus has collected beneath the nail, which generally falls off, and a new one soon grows.

[This whitlow is **Abernethy**'s *Paronychia ungualis*. It begins with slight inflammation, accompanied with a throbbing, and by degrees raises up a small white semi-transparent bladder, the whiteness of which depends on the thickness and opacity of the cuticle. It seems, as **Le Dran** says, to be " only a disease of the skin, which, being slightly excoriated or irritated from some external cause, inflames, and is followed by a collection of purulent serum between the cuticle and true skin." (p. 413 ; Fr. edit., p.539.)]

If the whitlow be left without puncture, it continues increasing, stripping the cuticle of the true skin, and distending it more and more, till at last, finding a crack or a thin part, it bursts, and the pus is discharged But the continued pressure has ulcerated the cutis and then, as **John Hunter** observes, " the soft parts underneath push out through the opening in the cuticle, like a fungus, which, when irritated from any accident, give a greater idea of soreness, perhaps, than any other morbid part of the machine ever does. This is owing to the surrounding belts of cuticle not having given way to the increase of the parts underneath, by which means they are squeezed out of this small opening, like paint out of a bladder." (p. 470.)

(*a*) Phil. Trans., 1720, vol. xxxi.

(*b*) Institutes and Practice of Surgery, vol. i.

Hunter gives the following reasons (the correctness of which must be readily admitted) why the abscesses "about the nails, commonly called whitlows, more especially in working people, give so much pain in the time of inflammation, and are so long in breaking, even after the matter has got through the cutis to the cuticle; the thickness of the cuticle, as also the rigidity of the nail, acting in those cases like a tight bandage, which does not allow them to swell or give way to the extravasation; for in the cuticle there is not the relaxing power, which adds considerably to the pain arising from the inflammation; but when the abscess has reached to this thick cuticle it has not the power of irritation, and therefore acts only by distension; and this is, in most cases, so considerable as to produce a separation of the cuticle from the cutis for a considerable way round the abscess." (p. 469.) * * * "All of which circumstances taken together, make these complaints much more painful than a similar-sized abscess in any of the soft parts." (p. 469.)]

Second. When the inflammation is situated in the cellular tissue beneath the skin, and commonly at the bulbous end of the finger, the pain is very severe on account of the tension of the thickened skin. If the inflammation pass into suppuration, fluctuation cannot readily be perceived, and the pus makes itself an outlet with difficulty.

[This form might not inaptly be called *Paronychia cellulosa*, as, in the inflamed cellular tissue of other parts, the inflammation is disposed to spread; the whole finger often becomes affected, and the disease occasionally extends into the hand itself. The severity of the pain is great, because, as **Le Dran** observes, "the skin of the finger is of very close texture, and therefore cannot yield to the increased size of the inflamed parts which it encloses, consequently the tension, pain, and fever are more violent." (p. 414; Fr. edit. p. 542.)]

Third. If the inflammation be situated in the *sheaths* of the tendons, the pain, which is specially situated on the front of the finger, is very severe, and strikes up through the whole arm to the shoulder; upon the finger only a slight swelling is to be observed, but it spreads so much the more over the greater part of the hand to the wrist, and even to the fore arm. Severe fever usually accompanies it. If the thumb, fore, or middle finger be attacked, the pain ascends outwards upon the front of the hand; but, if the ring or little finger be attacked, then the pain is continued along the ulnar surface to the elbow-joint and up to the arm-pit. When suppuration occurs, fluctuation is not distinguishable on account of the deep situation of the pus. The inflammation readily spreads to the periosteum, and destruction of the phalanges often ensues.

[This form is **Abernethy's** *Paronychia tendinosa.*

Travers (*a*) observes that "this, the case of acute paronychia," as he calls it, "is frequently accompanied with absorbent inflammation, but not invariably; nor is it on this account more serious. Matter is secreted by the inflamed synovial surface of the tendinous sheath, or the particular fascia investing the tendinous extremity of a muscle of the arm or leg; or beneath a ligamentous expansion, as the palmar or plantar aponeurosis." Sometimes the symptoms supervene in a few hours after the injury, sometimes not for days, so that the patient scarcely recognises the injury, usually a small penetrating wound. If the wounded thumb or finger is disfigured by excessive œdema, the symptoms of disturbance are less severe than when, with great tension, the swelling is inconsiderable and void of fluctuation, so as to make the existence of matter doubtful. The quantity of pus is so small, and the relief of discharging it so great, as to demonstrate that its situation alone had given rise to the intense pain. Is it owing to the partial escape of matter into the cellular substance, or to the inflammation having originally attacked this texture, exterior to the theca or fascia, and affected the interior only by sympathetic connexion, that the symptoms are less urgent when the œdema is present?" (pp. 216, 17.)

Le Dran considers this form of whitlow to differ from the preceding in not being consequent on phlegmonous but erysipelatous inflammation: and he does "not think that an erysipelas affecting these parts, and forming a whitlow can proceed from an in-

---

(*a*) On Constitutional Irritation, part i.

ternal cause, as other tendons are not found subject to this disorder: but it may be owing to a puncture which has affected the tendon, together with the sheath, or even the sheath alone. These two parts, we know, are blended together at the third joint where the tendon is inserted into the bone: it is therefore no wonder if inflammation of the one should extend to the other. The inflammation spreads afterwards all over the hand and along the muscle from which the tendon arises, as far as to the fore arm, sometimes even to the whole arm, forming an erysipelatous inflation, which terminates under the arm-pit, and swells the axillary glands. The pain and fever are then very violent, attended sometimes with delirium and convulsions." (p. 419; Fr. edit., p. 547.)

This tendinous and the cellular whitlow just described are continally running one into the other from continuous sympathy; and, under one or other form, or a compound of both, often appears the result of punctured wounds, (which will be heareafter considered, *par.* 328.) especially those most dangerous and often fatal received during dissection. The inflammation set up in the tendon or its sheath, and propagated from the one to the other, as described by Le Dran, is always accompanied with inflammation of the neighbouring cellular tissue, and, as Chelius observes, often spreads to the periosteum, which, separating from the bone in consequence of the effusion of matter beneath it, and often participating in the slough of the theca and tendon, which not unfrequently, though not so constantly, happens in this disease, that we can agree in Le Dran's definition, that it is "not a phlegmonous abscess, like the second kind, but a putrefaction either of the sheath alone or the tendon with it." Under these circumstances, the bone is destroyed and exfoliates, which is commonly a very tedious though not dangerous process.—J. F. S.]

Fourth. On the inflammation taking place in the periosteum; the pain is excessively severe, though not spreading over the hand and fore arm; the affected finger at the beginning is not at all swollen; it soon suppurates, and the bone is attacked.

The severe kinds of whitlow may be connected with each other inasmuch as a less may pass into a more severe form. In the spreading of the inflammation over the hand, painful swellings may occur in various parts.

A painful state, near the nail of the little finger, without any previously apparent inflammation, has been observed, which Richter calls the *dry whitlow*, in which the pain continues for minutes or hours, and then disappears for days or weeks. On amputation of the finger all the soft parts are found natural, but the bone converted into a mass resembling fat (*a*).

[Abernethy calls this *Paronychia osseosa.*

Le Dran asserts "that this species of whitlow proceeds from a disease of the bone, in consequence of which the periosteum soon putrefies, or is attacked with an erysipelas which degenerates into a putrefaction: from whence it happens that, when making an opening, the bone is found bare and frequently carious." He observes that "the inflammation seldom extends over the fore arm, as described in the preceding kind." (p. 420; Fr. edit., p. 550.)

I do not recollect to have distinguished this disease, and doubt much whether the indications mentioned are sufficient for that purpose.—J. F. S.

Abernethy speaks of "an ulceration with great thickening at the end of the fingers, and toes, and pain particularly at night, which has been described under the name of *Epinychia.* It goes on producing disease of the skin, and no nail will grow, or perhaps the disease extends and leaves a little island of nail, and this I have seen plucked out as the cause of the disease, though it was really the only sound part. I have seen it go on for three years and not get well. It is the produce of an ill state of health." (*b*). I presume under this name Abernethy refers to the disease called by Sauvages (*c*) *Epinyctis;* he describes it, however, as a pustule rising in the night, resembling a boil, of a blackish red colour, crowding together three or four lines in diameter, affecting chiefly the legs, and very frequently painful, especially at night. He describes two species,—*E. vulgaris,* and *E. pruriginosa.*

John Pearson speaks of a *Venereal Paronychia,* which he describes as appearing in the form of a smooth, soft, unresisting tumour, of a dark red colour, and situated in the cellular membrane about the root of the nail. It is attended with an inconsiderable degree of pain in the incipient state; but, as suppuration advances, the pain increases in

---

(*a*) Ackill, Chirurgische Vorfalle, Gott., 1777, vol. p. 210. (*b*) MS. Lectures on Surgery.
(*c*) Nosologia Methodica. Amsterdam, 1768. 4to. vol. i.

severity; its progress towards maturation is generally slow, and seldom completed. When the sordid matter it contains is evacuated, the nail is generally found to be loose, and a very foul, but exquisitely sensible ulcer, is exposed; considerable sloughs of cellular membrane, &c., are frequently exfoliated, so that the cavity of the sore is often very deep. The discoloured and tumid state of the skin commonly extends along the finger, considerably beyond the margin of the ulcer; in such cases, the integuments that envelop the finger become remarkably thickened, and the cellular membrane so firmly condensed as not to permit the skin to glide over the subjacent parts. The bone is not usually found in a carious state. This species of paronychia is more frequently seen among the lower class of people, when they labour under *lues venerea,* than in the higher ranks of life. It does not appear to be connected with any particular state of the disease, nor is it confined to one sex more than the other. In the Lock Hospital it occurs in the proportion of about one patient in five hundred." (pp. 85–7.) It is evident, however, that **Pearson** is not quite satisfied as to the actual nature of this disease, which seems more to resemble *onychia maligna* than any other form of whitlow; for he proceeds:—"When I adopt the name of venereal paronychia, it is not with the design of *implying that this is a true venereal abscess,* containing a fluid which is capable of communicating syphilis to a sound person. Its progress and cure seem to be unconnected with the increased or diminished action of the venereal poison in the constitution, and to be also uninfluenced by the operation of mercury. I consider the venereal disease as a remote cause which gives occasion to the appearance of this, as well as several other diseases, that are widely different from its own specific nature." (p. 88.)]

186. The causes of whitlow are in many cases unknown; it is often, however, very common at certain periods. Sometimes a general cause, as gout, and rheumatism, seems to give rise to it; but, in most cases, the cause is local, as contusion, sudden warming of the fingers after they have been chilled, injury with fine puncturing instruments, from splinters, and so on.

To these causes **Garengeot** adds "the excrescences (or rather little shreds) which form about the nails, and are commonly known as *hagnails.*" And he observes, "that workwomen using the needle are most subject to whitlow; though, on the other hand, they protect themselves by immediately sucking their finger, thus imitating the suckers of wounds, or certain irregular practitioners; because, by this proceeding they abstract the blood which escapes from the little vessels opened by the sharp instrument, and thus prevent any deposit, and consequently also abscess." (pp. 287, 8.) Another very common cause of whitlow is the impure soda often used by laundresses in washing linen, which often either irritates any small scratch or crack there may be in the skin of the finger, or even first produces a cleft which presents the appearance of a knife having been drawn through the cuticle down to the cutis, and then, irritating the latter, sets up considerable inflammation in the shape of whitlow.—J. F. S.

Hunter takes the whitlow as an example of "the ulcerative process having no power over the cuticle, so that when the matter has got to that part it stops, and cannot make its way through till the cuticle bursts by distension." (p. 469.)]

187. The *treatment* of whitlow varies according to its different forms. In the *first* form, it may often be at the very onset dispersed by cold applications. If pus be formed, it must be soon evacuated, that it may not spread beneath the nail. If the nail, however, be loosened, it must be partially removed with the scissors, and a piece of linen spread with cerate must be laid between the edge of the nail and the soft parts, in order to prevent the irritation of the latter. If pus be collected beneath the nail, the latter must be scraped thin, so that it may be pierced with the bistoury, and the pus allowed to escape; or, if the nail be somewhat loose, it may be torn off. Generally, as it separates a new nail grows; it should be covered with wax, to give it a good shape.

[**Gibson** says "venesection, both general and topical, may be required in the early stages of whitlow; leeches especially prove very serviceable in all cases, by abating pain and reducing the inflammation These remedies, however, are seldom sufficient to procure resolution; but this has often been accomplished by the early and repeated applications of a *blister*. On the other hand, it must be stated that many patients derive no advantage whatever from the blister." He further, and very justly, notices :—" The same applications, I have observed, produce very opposite effects on different patients: thus I have known common linseed oil spread over a whitlow afford instantaneous relief in some cases, and, in others, so far from proving beneficial, aggravate all the symptoms. Soft soap or common brown soap, warmed and applied to the affected part, occasionally acts in a wonderful manner, assuaging the pain and subduing the swelling in a very short time. Poultices sometimes give relief, and are useful always in softening the skin and removing tension; but, when the swelling is very great, the pain intense, and matter evidently formed, the most effectual mode of easing the patient is to lay the part open freely with the knife." (p. 188.)

HUNTER observes, that " the application of poultices in these cases is of more benefit than in any other, because here they can act mechanically, viz. the moisture being imbibed by the cuticle as in a sponge, and thereby softening the cuticle, by which means it becomes larger in its dimensions, and less durable in its texture." He advocates of course the early opening of these abscesses; and, speaking of the fungus which almost invariably protrudes through, as also when the skin gives way of itself, he says :—" It is a common practice to eat this down by escharotics, as if it was a diseased fungus; but this additional pain is very unnecessary, as the destroying a part which has only escaped from pressure cannot, in the least, affect that which is within; and, by simply poulticing till the inflammation and, of course, the tumefaction subsides, these protruded parts are gradually drawn into their original situations." (p. 470.)

With the practice of freely opening the whitlow I fully concur, and the sooner it is done after suppuration has taken place, and the cuticle is raised like a blister from the true skin, the better. The suppuration takes place usually in twenty-four or forty-eight hours from the onset of the disease, and should be carefully watched that it may be punctured immediately the pus has been poured out. The longer cutting through the skin is delayed after this event, so much the worse; for, beside the separation of a larger extent of cuticle and even of the nail, and the continuance of violent pain from the pressure which the pent-up matter makes on the sensitive extremities of the nerves at the tips of the fingers, the pus presses also on the cutis and causes it to ulcerate, thereby rendering the cure at best tardy; and often producing a very ugly and tiresome sore. After the pus has been discharged by puncturing or cutting through the cuticle, it is best to notch out a little bit of the skin, to ensure a free and constant escape for the matter, otherwise the cut edges often become glued together by the drying of the pus between them, and then it again collects, and sometimes needs a fresh cut. If the pus be confined beneath the nail, as is sometimes the case, the nail having been scraped, it should then have a little hole carefully cut through it to let the matter out. It rarely happens that the whole nail at once separates from the true and highly sensible skin beneath, but is held sometimes at the root, side, or end according to the part at which the pus has been poured out. I do not think it advisable to thrust in lint to save the soft parts beneath, as scraping the centre of the nail, from root to tip, till it will bear scraping no longer without bleeding, or, in other words, till it is almost completely scraped through, allows the edge of the nail so to alter its place that little or no irritation is produced by it. All that is necessary is to give free vent to any matter which may exist, to keep the parts clear from any dirty or irritating substances and to prevent the loosened part of the nail (the movement of which causes much pain) being disturbed, which is best done by wrapping in a poultice, or covering with wax and oil dressing, for I am not disposed to remove any part of it so long as the cutis beneath continues suppurating, as the nail protects it best, just as the cuticle does a blister-sore, and, as the new nail forms, it gradually stretches beneath it, and then, but not till then, may portions of the old separating nail be cut off. If, however, as is sometimes the case, the loosened nail digs in and irritates the sore; if the cutis have ulcerated in consequence of the pus not having been evacuated sufficiently early, or, if it twist up, as it will occasionally do, and continually catch in the dressing, then it may be cut off. I am no advocate for tearing off the nail, nor any part of it, and I can scarcely imagine that in this form of the disease it is ever necessary.—J. F. S.

HIGGINBOTHAM advises brushing over the whitlow with nitrate of silver, and considers it very good practice. I have not, however, had any experience of it. GIBSON mentions that PERKINS of Philadelphia is said to have frequently removed whitlows in a very short time by an admixture of corrosive sublimate and white vitriol, applied to the part on lint steeped in tincture of myrrh, and suffered to remain for several days. GIBSON has tried the remedy in several instances, but cannot say it has answered his expectations in any one case. (p. 189.)]

188. The *second* form of whitlow requires, in consequence of the severity of the inflammation, bleeding or leeches to the affected finger, cold applications, and rubbing in mercurial ointment. If the cause of the whitlow be a puncture, it must be ascertained whether any splinter remain; and, if so, it must be removed; also, if any noxious matter have penetrated into a wound, it must be carefully washed out with warm water. If resolution do not occur in the first three days, the affected part must be cut into. The patient is always thereby relieved, either by the escape of the pus, or, if the pus be not perfectly formed, by the division of the tough and tight skin, and by the bleeding. The cut should always be pretty free. Soothing poultices should be applied till the pain and swelling have subsided. If the skin be thinned to a great extent, and raised like a bladder, it must be removed as soon as the pus is discharged.

[The treatment of this is precisely similar to that directed for the previous form of the disease, excepting that, in the present case, it is always necessary to cut through the cutis as well as the cuticle, and relieve the tension of both at once; the pus, if the incision be made at the proper time, not having yet ulcerated through to the cutis, and poured itself beneath the cuticle.—J. F. S.]

189. The *treatment* of the *third* form of whitlow is the same as in the second, except that the incision must not be deferred beyond the third day; for, otherwise, the tendon will be destroyed. The cut must penetrate into the tendon sheath. The pain is usually quickly diminished by the application of soothing remedies. As the inflammation often spreads over the whole hand, if in any particular part pain, swelling, and fluctuation occur, it must be opened: and as, when the tendons are destroyed, the motions of the finger are lost, care must always be taken to keep it in a proper position.

[The incision, when the sheath of the tendon is concerned, should always be made deeply and freely, and in the course of the tendon, as if that be divided longitudinally, no inconvenience accrues to the movement of the finger or toe, as would were it cut transversely. It must not be expected always to find pus flow in opening the tendon-sheath; very frequently but a drop or two escapes, and sometimes none, the secretion not having been established. The anticipation of such occurrence is not, however, to be any bar to making the incision, as the immediate relief it affords, by getting rid of the tension, and emptying the vessels of the inflamed part, and checking the high constitutional disturbance almost always attending inflamed tendinous structures, is most remarkable. If the inflammation and suppuration be propagated to the palmar or plantar fascia, or further on the arm or leg, incisions through the fascia must be made, for the voidance of the pus. As this subject will be again treated of, in considering punctured wounds, it need not at present be further pursued. As regards the sloughing of the tendons of the fingers or toes, the extent to which they are destroyed is very great: indeed, I have known an instance of slough of the entire tendon, up to its junction with the muscular fibres, of one of the flexor muscles of a finger, of which the top had sloughed off. The straight position is best for the finger, when either flexor or extensor tendons has sloughed; but very commonly, for working persons, its immobility is so inconvenient, that it is necessary to amputate it at the knuckle.—J. F. S.]

190. The *fourth* form of whitlow must be *treated* the same as the previous forms; and, if the severe pain and tightness do not diminish, an early cut through the whole must be made, to prevent the destruction of the bone. This must be made where the pain is most severe, and must be carried down to the bone. The finger must be put in decoction of chamomile if the suppuration be sluggish; it must be bathed in lye (*a*), and soothing applications employed. The bone of the last finger-joint often separates, or may be removed frequently without pain, the finger retaining its form, though rather shorter. If the bone of the second or first joint be affected, the removal of the finger is necessary. However, under the pre-

---

(*a*) Common mixture of crude potash and water.

ceding treatment of soothing poultices and bathing with chamomile, the most severe cases of this kind are often cured.

[For the cure of Epinychia ABERNETHY recommends the use of "a combination of arsenic and sulphur, which, together with some herbs, formed the principal part of a quack medicine called PLUNKET's Epithema; that composition, however, was horribly painful, and produced the most horrible sloughs, not by decomposing the parts, but by exciting vehement action; I have, therefore, followed it so as to render it only a corrigent, and, in many cases, it will relieve without producing pain." For the same purpose he used also successfully the *Aqua Arsenicalis* of St. Bartholomew's Hospital, consisting of arseniate of potash, spirit, and mint water, which he considered to have an excellent corrigent effect on local diseased action. It is also well to use it mixed with basilicon; but care must be taken in its employment, for if the constitution become affected, as sometimes happens, it will make the patient very ill, and even cause temporary blindness.]

191. It is here proper to mention two diseased conditions which depend on changed form and direction or unnatural structure of the nail, or are therewith connected; *growing of the nail into the flesh*, and *inflammation and suppuration of the surface producing the nail.*

192. The Ingrowing of the Nail into the flesh depends less on an increase of the breadth of the nail, than on the pressing upwards of the soft parts. It is ordinarily consequent on squeezing together of the toes by tight shoes, especially if the nails be cut too short, and is almost confined to the great toe, specially to that side of it next the second toe. The irritation of the edge of the nail causes inflammation; at first, the secretion of a serous fluid which dries to a callous mass; subsequently suppuration and fungous excrescences spring up, which spread over the nail; the disease may even assume a carcinomatous character, or the inflammation may extend to the bone. The nail itself grows thicker, and is frequently softened at the ulcerated part. The pain in the severe form of this disease is always very great, and walking often becomes quite impossible.

[The commencement of this disease has been well-described by WARDROP, who says:—"This affection is chiefly confined to the great toe. It frequently happens, when the foot is kept in a tight shoe, that the soft parts situated on the edge of the nail thicken, are pressed over it, and become more or less inflamed and painful. If the inflammation and thickening of the soft parts increase, the edge of the nail becomes at last completely imbedded in them, and its sharp edge, from the pressure of the body when resting on the foot, increases the inflammation, and produces suppuration of the contiguous soft parts. Thus the hard and sharp nail, by pressing on the surface which has become ulcerated, causes great pain and lameness, and in many cases, prevents the person from walking. The ulceration generally extends round a considerable part of the nail, and a fungus arises from this surface, accompanied by excessive irritability." (p. 130.)

This, "the first variety," says DUPUYTREN, "consists of the ulceration sometimes of one, sometimes of both the lateral edges of the nail at once. It almost always happens on the outer edge. If the conformation of the nail be remembered, if the flatness of its body, the direction of its corners, its situation in the thickness of the skin which surrounds and covers it, we may easily conceive how a tight or ill made shoe, producing a constant pressure on the nail, will forcibly thrust its corners upon those parts of the skin where it rests. By degrees these corners, always more or less sharp and cutting, bury themselves into the skin, with the greater facility as the skin itself pushes upwards and outwards, and endeavours to cover them; finally, the irritation increases by walking, and produces a very painful inflammation. Such is really the most common cause of the incarnation of the outer edge of the great toe. The affection almost always commences at the point of union of the front with the side edge of the nail, and appears to be occasioned by the fold that forms in the flesh; as this interrupts the action of the scissors while cutting the nail, they are almost invariably checked before they can cut away the whole of its front edge, especially at that point where an angle is formed by union of the nail with its corresponding lateral edge. This allows the remaining nail to grow, which soon forms a sharp point, punctures, and cuts into the flesh, and gives a sort of signal of ulceration which soon spreads along the corresponding edge of the nail. So sure is it that this point is constantly found on the nails which have been torn off. Scarcely has the nail cut itself into the skin it covers, than the pain becomes very severe; walking, and even standing, are unbearable; a serous or sero-purulent oozing establishes itself in the part affected, and, if the patient take exercise, the whole foot swells. The pain, however, continues increasing, the oozing becomes more abundant, and the sanious pus which escapes has a smell more fetid from mixing with the perspiratory humour of the feet. The patient, tormented with pain, is driven to raise the nail and cut it back; but this proceeding, though sometimes causing momentary relief, far from curing increases the difficulty of the treatment. Finally, if the disease be left alone, the ulcer produced sometimes runs into a cancerous state, sometimes is covered with enormous vegetations, sometimes even the inflammation is propagated to the periosteum, and soon gives rise to caries and necrosis of one or more phalanges." (p. 46.)

Dupuytren also mentions that this disease is liable to be confused with some others, and instances a case which, for eight years, had been treated as if depending on gout.

Colles (a) observes, that "the colour of the fungus is rather florid; surface is smooth; the discharge is purulent, in small quantity, and tolerably healthy, unless the part have been irritated by too much exercise of the limbs, or by some external inflammation or local injury: there is little or no surrounding inflammation, no enlargement of the toe, and the pain is in general trifling, unless during exercise, when the weight of the body on the limb causes the nail to press into the soft substance of the fungus, which thus often induces considerable uneasiness and lameness. This disease does not appear to me to have any tendency to spread to, or to involve, the adjoining parts, as I have seen cases in which it has remained stationary for some months, and in one for two years; at the end of which period the symptoms were in no way more severe than at the commencement, although most writers assert that it generally passes into malignant onychia. The origin of this troublesome affection is usually attributed to the effects of a tight boot or shoe, or to some accident in cutting or breaking off the end of the nail; in many instances, however, no cause can be recollected or assigned for its occurrence." (p. 241.)

Colles, however, speaks of the form of disease liable to be mistaken for gout as quite distinct from that just described. He says:—"There is another morbid affection which occasionally engages the anterior and inner angle of the great toe nail, and which causes considerable lameness and uneasiness, particularly on pressure; this affection is often mistaken for an attack of gout, especially in those persons where such an attack may be expected or even desired. In this disease there is no swelling or redness; but pain, on pressure, at the anterior and internal angle of the nail. On close examination of this spot, we find that this angle rests on a hard white mass of laminated, horny cuticle, which we can easily remove in bran-like scales, when we shall see a small cup-like cavity, without any ulceration or disease. The ungual angle appears thick and bulbous opposite this point, and the pain is caused by its pressing against this mass. * * * I may remark I have never seen this disease engage the outer angle, neither have I seen that last described engage the inner angle of the toe-nail." (pp. 244, 5.)

193. In the slighter forms of this disease, it may always be easily relieved by inserting a slip of lead under the edge of the nail which is to be fixed, there by twisting round it a piece of sticking plaster; by which means the nail is raised and the flesh depressed. If there be fungous excrescences, these must be first removed with lunar caustic, or cut off with the knife. It would be too painful at once to insert the plate of lead beneath the edge of the nail; but it is also unnecessary, as its insertion under the front edge, if the nail be allowed to grow, gradually raises the hind part, and then the lead may be further introduced. When the nail has recovered its proper direction, it must not be cut too short nor rounded at the sides, but only shortened transversely. With these precautions, this treatment, recommended by Desault and Richerand, has, in almost all cases, answered my wishes. Introduction of charpie or wax beneath the edge of the nail is useless.

Biessey (b) scrapes the whole free surface of the nail till nearly its entire thickness is destroyed, particularly in the centre. Then he touches the scraped part five or six times, more or less severely, with lunar caustic until the nail contracts completely, and draws out of the flesh. He then lays pads of charpie under the edge of the nail, till by its growth it stretches over the bulbous part of the toe. Zeis (*a*) especially recommends the introduction of charpie under the edge of the nail, and the use of foot-baths.

(a) Observations on some Morbid Affections of the Nail of the Great Toe; in Dublin Journal of Medical Science, vol. xxiii. 1843.

(b) Remarks on Inverted Toe-Nail; in Philadelphia Journal of Medical and Physical Sciences, vol. ii. 1821.

[The treatment recommended by Meigs (*b*) is very simple:—"Let a small pledget of lint, just large enough to cover all the granulations, and of sufficient thickness to act as a compress, be neatly adjusted, over which a roller of linen, three-quarters of an inch wide and eight or ten inches long, is to be applied, having one end previously spread with adhesive plaster. By this method we are enabled, with great ease, to make it not only act on the compress, which will destroy the granulations very rapidly, but, by confining the toe and nail, to prevent even the small degree of sliding motion or friction of the latter over the wounded part, thus doing away one principal cause of the disease. By pursuing this treatment, the patient will generally recover, even while walking about." (p. 266.)

Astley Cooper says, that "the application of a blister will bring away the cuticle, and often the nail along with it." (p. 193.) I have tried this plan several times, but have rarely succeeded in inducing the separation of the nail.—J. F. S.]

194. It is not possible, however, in many cases to render assistance by this treatment, partly because the nail has gone in too deeply, and is too much covered with fungous growths, partly because it is too painful. Here the treatment proposed by Dupuytren is applicable. When the inflammation of the toe is diminished by poulticing, rest, and so on, a pair of straight sharp scissors, of which one branch is very pointed, must be thrust by a sudden motion from before backwards, from the front edge to the middle of the root of the nail, to at least three lines behind its hinder edge, thus dividing the nail into two halves. The diseased halves are then to be taken hold of and twisted round, all connexion destroyed, and the nail itself removed; the same must be done with the other half, if necessary. If the fungous excrescences are high, they must be destroyed with caustic, by which the skin beneath the nail dries, the sore surface disappears, and in from twenty-four to forty-eight hours is cicatrized. In old persons the nail is generally not replaced; in young persons it sometimes reappears; a recurrence of the disease is, however, rarely to be feared.

[According to Scoutteten (*c*), if it is determined to destroy the matrix of the nail, the point of a straight bistoury should be placed upon the middle of the diseased phalanx, about four lines from the edge of the nail, and the skin divided down to the nail. The cut should not penetrate deeper than the matrix, as this only is to be exposed. The edges of the wound are then to be raised from the nail and kept asunder by the introduction of charpie. On the day following the little wound must be filled with a caustic paste, (five parts of caustic potash, and six of quicklime, moistened with alcohol immediately before use,) and the dry phalanx covered with sticking plaster, the excrescences must be destroyed by the gradual application of the caustic; and, after the falling off of the slough, until the healing is complete, which takes place usually in twenty-four days, there is nothing to do except merely to cut away the exposed edges of the nail with scissors.

The following are Paré's and Faye's treatment. The former consists in thrusting in a straight bistoury at the base of the soft parts which cover the nail, and dividing this part from before backwards to the edge of the nail, then the bistoury is to be turned to the other side, and the flap perfectly removed. Cauterization is to follow. In Faye's method a V-shaped piece of the nail (first scraped thin) must be removed out of the front edge, and through the two edges a metal wire drawn and twisted together, by which the edges of the cut are approximated, and the in-growing edge of the nail raised up.

Of the various modes of treatment which have been recommended for the cure of the in-growing nail, compare Michaelis (*d*), Sachs (*e*), Zeis (*f*).

Astley Cooper first proposed the operation of, "with a pair of scissors, slitting up the

(*f*) Above cited.

nail on that side where the disease exists, and then with a pair of forceps turning back and completely removing the divided portion. This is a very painful operation certainly; but I have known persons get well by this treatment in ten days, where the complaint had for months resisted every other. The applications to be used after the operation are of little importance; poultices are the best, and these will be required but for a very limited period, for the irritating cause having been removed, the fungus will soon disappear." (pp. 192, 3.) Nearly the same plan was followed by **Dupuytren**, as above described.

I entirely concur, however, with the observations made by **Colles** on this point. He says:—"This operation inflicts a great degree of suffering, because in this disease the nail is not, as in onychia, separated from the vascular and highly sensitive matrix, except only through a small extent of space, not more than a quarter of an inch at its external angle, and, therefore, the scissors pushed upwards between the nail and the adherent matrix, and the forcible evulsion of the former by the forceps, must cause exquisite pain, which, though of short duration, can be regarded as nothing short of actual torture. * * * I am by no means an advocate for this peculiarly painful and distressing operation, but, on the contrary, I believe we may be relieved from the necessity of performing it, and that we can, in all instances, effect a permanent cure by a very simple operation, and one comparatively free from suffering; namely, by confining the excision of the nail to so much only as is already detached from the matrix; all of this portion, as well as that imbedded in the fungus, must be removed." His operation consists in having the fungus pressed down with a spatula, and the edge of the portion of nail to be removed seized with strong flat-blade forceps; the flat end of a probe is then thrust beneath the nail as far as it will go directing it towards the outer edge, and upon the pointed edge of a pair of stout crooked scissors is to be carried, with one stroke of which the detached portion of nail is cut off, and then drawn away by the forceps with moderate force. But, if this be insufficient, the probe is to be passed still higher, the scissors introduced again, and a second cut frees the nail: sometimes a sharp momentary pain occurs from the point of the scissors penetrating the sensitive matrix. The only dressing required is "a small bit of dry lint, to be pressed firmly between the fungus and the edge of the nail." In a few hours the toe is free from pain, and the patient can walk without any lameness or uneasiness in three or four days after the operation. The dressing continues perfectly dry, and need not be changed till the fourth day. At this time the fungus will be found much reduced in size, perfectly dry, and of a firmer consistence. * * * In the course of ten or fifteen days the fungus will have entirely disappeared, and the parts be restored to a healthy state. * * * The result of the operation is not in all cases so successful, for, in some instances, four or five days after the operation, the patient will complain of some uneasiness in the toe, when we shall find on examination that the dressing is moistened with a little discharge, and that a small portion of a whitish substance, like soft and swollen leather, is rising up through the fungus. This substance, may be, regarded as a sort of accessory ungual filament, arising close to the original nail, from the anterior and outer border of its matrix, and which is now altered in texture and direction; this filament is so soft that it breaks and tears, if caught by the common dissecting forceps." (pp. 243, 4.)]

195. The Inflammation and Suppuration of the Surface which produces the nail, (**Dupuytren**'s matrix of the nail,) which **Wardrop** has pointed out as a peculiar kind of whitlow, (*Onychia maligna,*) begins with dusky redness and swelling of the soft parts in the neighbourhood of the nail; an ichorous fluid oozes between the nail and soft parts; ulceration takes place at the root of the nail; the neighbouring parts become swollen, dusky red, and the pus which the sore secretes is ill-conditioned and stinking. The nail loses its colour, becomes gray or black, and does not grow, so that it shortens and loses half its width; sometimes it entirely disappears, and only a few streaks of horn are seen here and there; sometimes part is concealed under the fungating flesh; in many cases it is completely separated. This state may continue for many years, and the toe or finger become converted into a shapeless mass. This disease is frequently very painful, especially when touched; the fungations (which do not, as in simple ingrowing of the nail, arise on the side, but are seated at the root of the nail) bleed, on walking and standing.

[As **Dupuytren** observes, "the formation of this second species will be better understood after saying a few words on the anatomical structure of the nail. Its adherent extremity, the only part at present needing study, is implanted in the skin in a peculiar manner; the latter, having passed on the dorsal surface of the nail, is reflected, and, having reached the hind end, divides, into two portions, the epidermis which covers the whole superficial layer, and the cutis which passes beneath the nail, and is continuous with the skin covering the free extremity of the finger. The *cul de sac*, in which this part of the nail is received, is called the *matrix*. It is, then, very important to be acquainted with this disposition of the organ, as fully explaining why the nail received into the flesh is, in many cases, only produced by the ramming in (*refoulement*) of its free extremity into the *cul de sac*. This alteration may take place in consequence of the running over, or fall of a heavy weight upon the great toe. Whatever may be the cause, the patient at first complains when walking of a pain which gradually increases; the kind of *cul de sac*, lodging the base of the nail, reddens and inflames, as well as the bottom of the fold which receives its lateral edges; ulceration is soon observed, which makes rapid progress; its form becomes semilunar, its edges elevated and hard, its base red, violet, and livid. The nail shortens and diminishes to half its size, sometimes even entirely disappears, and in its stead are observed, here and there, pencils of horny substance; often, also, part of the nail is hidden under fungous flesh. These fungosities serve to distinguish this disease, resulting from primitive alteration of the skin, from that consequent on the nail digging into the flesh. When the disease is caused by the nail, the fungosities originating from the inflammation occur on the front and sides of the nail; but when, on the contrary, it depends on the affection of the skin, the fungosities are always observed at the root of the nail. The colour of the nail in these cases is gray and black; sometimes it does not retain its ordinary connexions; the sore is generally bathed in a sanious or sanguinolent suppuration, and spreads far and wide a fetid smell. If the patient walk, or even remain standing upright, the fungosities bleed: every kind of shoe is unbearable, and the least rubbing is extremely painful. In general it is impossible to remain in the same place with persons who have this disease, as the stench which circulates around them, and clings to their clothes, is infectious and penetrating, being produced by the union of the ichorous pus oozing from the bottom of the ulcer, and the copious sweat which the feet of these patients secrete." (p. 61–4.)

Colles mentions:—"When the original nail has been cast off, we usually see projecting from the sides, and tarsal border of the ulcer, a narrow plate of a white substance, not unlike white leather soaked in water; this sometimes forms one continuous shelf all around the ulcerated border, projecting in a peculiarly prominent manner, that is, rather at an angle to, instead of being a plane parallel with, the dorsal surface of the phalanx. In some cases this white substance (which is the result of an abortive attempt to produce a true nail) appears only in detached spots or flakes, the intermediate parts of the ulcerated margin being devoid of any such growths; they are most frequently seen at the posterior and anterior angles of the nail, but occasionally in other parts of the circumference. The surrounding integument is discoloured, being often of a livid or purplish tint; it is also indurated, and exudes a copious perspiration, of a peculiar heavy odour. This ulceration sometimes induces caries of the bone, and even extends to the phalangeal articulation." (p. 246.)

Wardrop says:—"In this state I have seen the disease continue for several years, so, that the toe or finger became a deformed bulbous mass. The pain is sometimes very acute, but the disease is more commonly indolent, and accompanied with little uneasiness. It affects both the toes and the fingers. I have only observed it on the great toe, and more frequently on the thumb than any of the fingers. It occurs, too, chiefly in young people; but I have also seen adults affected with it." (p. 136.)

"When the disease, more especially, attacks that part of the skin immediately beneath the nail, then," says **Dupuytren**, "is it observed to be raised by the development of little tumours, the presence of which cause pain in proportion as the pressure is more considerable. They are of different kinds, fibrous, cartilaginous, bony or vascular; and the proof of their development, simply depending on alteration of the cutis covering the nail, is, that if they are removed, without, also, taking away the skin from whence they spring, the skin generally, again, becomes diseased, ulcerates, and sooner or later requires complete removal." (p. 64.)—J. F. S.]

196. The causes of this disease are either *local*, mechanical, or chemical, for instance in persons having much to do with alkalies; or *general*, herpetic, but especially syphilitic, dyscracy. Several fingers and toes of both

hands and feet are then attacked at the same time; the disease commences sometimes with little sores in the clefts between the fingers or toes, which extend around the origin of the nails; these separate from their root. The disease ordinarily resists mercurials.

197. In the *treatment* of this disease internal remedies are to be employed, according to its different causes, and local, according to the degree of irritation; leeches, soothing applications, baths, and so on, and the foot kept quiet. **Astley Cooper** recommended a grain of calomel and opium night and morning with decoction of sarsaparilla, and the application of lint steeped in lime water and calomel, (*black wash*,) covered with oiled silk. If this treatment be ineffectual, the nail with its secreting surface should, according to the opinion of both **Dupuytren** and **Cooper**, be removed. According to **Dupuytren**, the foot is to be steadied, and the diseased toe held with the left hand; a deep semicircular cut is then to be made with a straight bistoury three lines behind the skin in which the nail is supported, and parallel to its fold. An assistant then holds the toe, whilst the operator raises the flaps from behind forwards with a pair of forceps, and dissects away the skin which produces the nail; if any shreds of nail remain they must be gradually destroyed. This operation is very painful, but of short duration. The toe must be enveloped in pieces of linen perforated and spread with cerate, and a thin bundle of charpie with a compress put upon it; the patient put to bed, and the foot half bent laid on a pillow. The pain subsides some hours after the operation, and, on the third or fourth day, when the bandage is removed, the wound is found covered with good pus, and is then to be simply dressed. The granulations are to be touched from time to time with lunar caustic; if new shreds of horn are formed, they must be pulled out, and the part producing them be cut away. Usually in from fourteen to eighteen days the patient can return again to his business. The scar is a smooth thick nailless skin, which sometimes acquires a horny consistence. If the disease depends on syphilis, **Dupuytren** treats it with *liq. hydr. nitr.*

I must deny the assertion that in this disease the tearing out the nail and the employment of caustic are of no effect. I have in several instances torn out the nail, and merely employed soothing poultices and bathing, and have effected permanent cure. I, therefore, only have recourse to extirpation when the above treatment has not any permanent result.

[In regard to the treatment of this disease, **Wardrop** says:—" The only local treatment I have ever seen relieve this complaint has been the evulsion of the nail, and afterwards the occasional application of escharotics to the ulcerated surrace. But even this painful operation in some cases does not succeed, and will seldom be submitted to by the patient; he must, therefore, either continue lame or submit to the removal of the member. Other surgeons have cut out the soft parts at the root of the nail, an operation equally severe." In preference, therefore, **Wardrop** recommends the internal exhibition of mercury, which he has found beneficial, " in small doses at first, and gradually increased, so as in twelve or fourteen days sensibly to affect the gums. The sores, in general, soon assumed a healing appearance after the system was in this state, and the bulbous swelling of the joint gradually subsided. The ulcers were dressed with wax ointment, so that the effects of the mercury might be watched; and, after the sore began to heal, a weak solution of the muriate of mercury and escharotics were occasionally used to clean the wound. The mercury was continued till the ulcers were perfectly healed, and, as is generally advisable under such circumstances, it was taken in smaller quantities for some time after the patients were apparently cured." (p. 138.)

Colles, admitting that "the complete removal of the entire of this diseased matrix does effect the cure in a very short space of time, provided the bone or joint is not diseased, (in which case amputation is inevitable,) and that subsequently rest and simple dressing will alone accomplish the healing process, the place of the nail being supplied by adverse hard skin," objects to the operation, not only for its severity, but because "it also too frequently happens, that the disease returns in some one spot or other, owing to the matrix not having been wholly eradicated, which, indeed, it is often extremely difficult to do, for the shape of the toe is so bulbous, and so deformed, the texture so changed and so condensed by chronic inflammation, and the edges of the ulcer are so raised over the part to be removed, that even an anatomist cannot easily recognise the relations of the several tissues involved in the disease, or ascertain the exact extent of the substance to be excised." Hence, "some days after the operation the patient becomes alarmed, by feeling a slight return of his former uneasiness, on any exercise of the limb, or any pressure on some particular spot, generally on one of the angles of the original ulcer; and on careful examination there is found still a little ulceration, and a fresh production of that ungual growth already described, and indicating the persistence of some of the diseased matrix." (pp. 246, 7.) This causes a repetition of all the suffering, and requires removal a second, or even a third time. Colles, therefore, prefers the following plan, which in a few days will induce a considerable amendment, and even a perfect cure in the course of three or four weeks:— * * * "I confine the patient to bed, and direct a poultice to the toe for two or three days. I then cleanse the ulcer carefully, by directing on it, from some height, a small stream of tepid water, from a sponge. I next cut away as much of the loose nail as I can, without paining or irritating the sensitive surface around, and then I fumigate the part by means of the mercurial candle, containing *hydr. sulph. rubr.* ʒj., *ad ceræ* ℥ij. This fumigation is to be applied night and morning, and, after each, the toe should be gently enveloped in lint or linen, lightly spread with *ung. spermac.* In four or five days the patient will express himself considerably relieved; the discharge from the ulcer will be found of a healthy, purulent character, and the appearance of the whole part much more favourable. The fumigation is to be still persevered in, and all projecting portions of nail to be closely cut. I consider this latter direction as very essential, as thereby the mercurial fumes can have more free access to the surface of the ulcer. In proportion as the ulcer improves it is interesting to observe, so does the condition of the growing nail; it acquires not only its natural firm and horny consistence, but also assumes its proper horizontal direction. For some time after the general surface of the ulcer has been healed, there still remain small spots of ulceration, generally at the angles around some white germs of new nail; against these points the full force of the mercurial vapour should be directed. This can be effected by adding a small conical wavy tube to the funnel. I attribute much of the success of this treatment to the use of the mercurial candle in preference to fumigation in the ordinary way. During this treatment the patient must absolutely abstain from walking or even standing on the affected limb; exercise but for a single day will counterbalance all the amendment produced by a week's rest and fumigation." (pp. 348, 9.) Colles did not employ any constitutional treatment in his cases, but he thinks it may sometimes be required.

I have never employed this mercurial treatment, and, therefore, only mention it on Wardrop's authority. Neither have I ever torn out the nail, nor dissected away the nail gland, although I admit that either is very efficient, because I believe they are horribly painful, and not absolutely called-for operations, and may, therefore, be avoided. The only advantage, as seems to me, resulting from their preference is, that the disease is cured rather more quickly. My own observation convinces me that cauterizing the nail gland with nitric acid is equally efficient, though not quite so speedy. It should be run quickly round the gland with a bit of stick in sufficient quantity to destroy it, otherwise a second application will certainly be needed; and, as soon as it has dried, a poultice should be applied. If successful, the nail in a day or two curls up out of the matrix, and gradually separates from the rest of its attachments; but if it do not, the acid must be applied again, and, if properly done, will not generally call for repetition.—J. F. S.]

198. The various parts of which the joints consist, stand in the most intimate relation with each other; therefore, in disease of any one, all the other parts are gradually drawn into participation. We speak of the *ligaments* and *synovial membrane*, the *cartilages*, and the *spongy ends of bones*. In each of these structures inflammation may be set up as the primary disease, which may be communicated to the others, and various organic changes be produced, which are described as *Articular Fungus*,

(*Fungus Articulorum*, Lat.; *Gliedschwamm*, Germ.; *Fongus Articulaires*, Fr.,) *White Swelling of the Joints*, (*Tumor Albus Articulorum*, Lat.; *Weisse Gelenkgeschwulst*, Germ.; *Tumeurs Blanches*, Fr.,) *Arthrocace*, *Dislocations from their original place*, (*Luxationes Spontaneæ*, Lat.; *Verrenkungen aus inneren Bedingungen*, Germ.; *Luxations Spontanées*, Fr.)

In reference to joints, Hunter (*a*) observes:—"They being circumscribed cavities, are subject to the same diseases as other circumscribed cavities, as inflammation, &c.; but their peculiar structure sometimes renders their consequences different. Nature is very little disposed to take on the adhesive inflammation, because the necessary consequence would be a loss of motion in a part originally intended for motion. This makes inflammation in joints so much worse than many other circumscribed cavities; for, as before observed, if adhesive inflammation does not come on, the inflammation and consequent suppuration must spread through the whole cavity. * * * Inflammation in joints is generally of more serious consequence than in other parts; even when resolved it is disagreeable; yet this is always to be wished for." (pp. 519, 20.)

199. *Inflammation of Joints* (*Arthrophlogosis*, Lat.; *Gelenkentzündung*, Germ.; *Inflammation des Articulations*, Fr.) is either idiopathic or symptomatic, and its course acute, subacute, or chronic. The causes are external injury, cold, and general diseases, which either of themselves or after the previous operation of local mischief produce disease of the joint, as scrofulous, gouty, rheumatic affections, syphilis, diseases of the skin, metastasis, suppression of the ordinary secretions, and so on. The reason of their beginning sometimes in the soft, sometimes in the hard parts, depends perhaps on the different relations in which the general and local causes stand to the production of the disease.

A.—OF THE INFLAMMATION OF THE LIGAMENTS.

200. When inflammation takes place in the fibrous structure of a joint, (*Inflammatio Ligamentorum*, Lat.; *Entzündung Gelenkbänder*, Germ.; *Inflammation des Ligaments*, Fr.,) it is only in certain stages confined to that alone; but, in its further progress, it spreads to the cellular tissue surrounding the capsule of the joint without, and the synovial membrane within. Its course is more or less acute or chronic.

[In regard to the rarity of affections of the ligaments independent of other parts of a joint, Brodie observes:—" The ligaments cannot be regarded as more exempt from disease than the fibrous membranes, which they very nearly resemble in their texture. It is not improbable that some of the pains which take place in the joints, in syphilitic affections, may depend on a diseased action occurring in the ligaments; and there can be no doubt that the long continued symptoms which occasionally follow a severe sprain, depend on these same parts being in a state of slow inflammation, in consequence of some of their fibres having been ruptured or overstretched. I cannot say that I have never seen a case where disease, independently of these causes, has originated in the ligaments; but I certainly have never met with a case where it has been proved to have done so, by dissection, and it may be safely asserted that this is a rare occurrence, and not what happens in the ordinary diseases to which joints are liable." (p. 7.)]

Among the "variety of cases," mentioned by Mayo, "in which the ligaments appear to be the parts exclusively or principally affected," is one arising from a blow on the knee, in which, "after many weeks confinement to the bed or sofa, the least exertion was followed by heat and pain in the knee. The joint was, in a slight degree, larger than the sound knee; but it contained no fluid; and pressure of the articular surfaces against each other, produced no pain. It caused no pain to rest his weight upon the extended knee; but when he stood on the other leg, and allowed the diseased knee to hang or swing, he felt uneasiness in it, which was greatly increased by twisting the knee. When he remained perfectly still, he would experience no uneasy feeling in the joint for several days together; and then, without any visible cause, the joint became a little heated and the skin slightly reddened. The same effects followed any deviation from the strictest

---

(*a*) Lectures on Surgery; in Palmer's Edition of his Works, vol. i.

rest." (p. 79, 80.) Now, if the injuring cause here mentioned as "a blow," be "a twist or wrench," from the foot slipping, or by falling on the hand, the symptoms are precisely similar in their immediate appearance, and their long continuance. Whether, in such cases, the ligamentous fibres are simply stretched beyond what they can bear with comfort, or whether they are actually torn, in however slight degree, is very difficult to determine; but that they at once become as painful before any inflammation can have been set up, as they afterwards are when they are said to be inflamed there is no doubt. Still, however, this seems the very utmost we know, and little enough it is, of inflammation of ligaments, and I fully concur in the following observations of WICKHAM of Winchester, who says:—"We have no reason, *à priori*, to suppose that the ligaments are not liable to primary disease, or that a lesion of these structures may not originate complaint, and propagate it to the other component parts of the joint. The result of my observation, however, has been, that the ligaments are the last of all the different parts diseased, and that it is very common, on dissection, to find the ligaments perfect and uninfluenced by disease, even when every other texture is either altered or destroyed. The intimate connexion of the capsular ligament with the cellular tissue which invests it, and the synovial membrane which lines it, renders it difficult to distinguish inflammation begun in the ligaments, from diseased action commencing in those other parts; and, in its first stages, I should think it impossible to detect it; in the latter stages it has so blended itself with disorganising effects of disease in other parts as not easily to be selected as giving rise to primary affections." (p. 98.)]

201. In *Acute Inflammation of the Ligaments* there is more or less severe pain, increased by pressure and motion, and accompanied with a feeling of heat and warmth; sometimes there is also an elastic, tense, not hard, shining swelling, which, in very severe inflammations, is red and extremely painful, and most prominent at those parts where the joint capsule is merely covered by skin and cellular tissue. The limb is bent. The pain is not simply confined to the joint; it spreads in the course of the tendons, and by the periosteum, over part of the limb, which frequently becomes œdematous. Fever is always connected with a high degree of this inflammation; frequently the fever precedes, and the inflammation follows it. If the inflammation do not subside, it spreads upon the synovial membrane, and then produces the changes hereafter to be mentioned; or it runs into a chronic condition, in which the pain subsides, but the swelling increases. If this inflammation come on less actively, *i. e.*, in a subacute form, it may continue a very long time.

[I do not know in what respect simple acute inflammation of ligaments differs from acute rheumatism; nor how they are to be discriminated primarily except by reference to the constitutional disturbance which, in this condition, is a very uncertain sign. But that they are different I think there cannot be a doubt; as, in the one case, the disease is propagated to the other parts of the joint, and the ordinary results of inflammation attacking mucous surfaces, viz., suppuration and ulceration, ensue in the cavity of the joint itself; whilst, in rheumatism, the affection is confined to the ligaments and the parts exterior to or enveloping them, and consists only in the effusion of serum or adhesive matter into the cellular tissue, thereby increasing the bulk and interfering with the motions of the joint. I must confess that I am ignorant of the signs which indicate simple inflammation of ligament, independent of rheumatism or of injury, and that I do not know the peculiar symptoms which point out the extension of inflammation to the ligaments, from the synovial membrane or proper tissue of joints. As seems to me, all our knowledge of inflamed ligaments is merely negative, except, perhaps, so far as concerns the injuries to ligaments known as sprains. I say perhaps, because in sprains the pain, on motion, which is held to be one principal sign of inflammation, occurs immediately after the accident, and before it is possible that inflammation can have occurred, however early that condition may, under these circumstances, be set up; and, if the part be carefully preserved in a state of repose, pain does not exist, nor is any other sign of inflammation present, although the slightest movement will produce excruciating pain; to explain the production of which, some other cause than inflammation must be sought for.—J. F. S.]

202. *Chronic Inflammation of the Ligaments* either begins with acute pain, or comes on gradually with a less degree of pain, observable only on

pressure and motion, and entirely subsiding when the patient is at rest; with a soft, doughy-elastic, colourless swelling, which frequently, like the pain, is but partial; usually, however, the whole joint is affected; it becomes shiny as the swelling goes on, penetrated with varicose veins, and is mostly somewhat warmer than the healthy parts, in which it is gradually lost. As the swelling increases, the limb wastes, becomes bent at the joint, and all extension is impossible, on account of the thickening of the ligaments and cellular tissue; the patient has the sensation of weight, weakness, heat in the whole limb, and is frequently, from time to time, attacked with severe pain.

203. Acute inflammation of the ligaments may be resolved under proper treatment, in which case simultaneous critical symptoms of fever appear, the inflammation subsides, and there remains only for a long time slight swelling and stiffness of the joint. Rarely, and only in rheumatic and gouty subjects, does metastasis take place to other parts. Very severe inflammation runs either into suppuration and abscess on the external surface of the capsular ligament, or, when continued, upon the interior parts, into suppuration of the joint and carious destruction, in which case the local and general symptoms hereafter to be described occur. In chronic inflammation the thickening of the ligaments, and the cellular tissue surrounding them, may be very considerable without the deep parts of the joint being attacked. This swelling is rarely dispersed entirely; generally, there remains thickening of the ligaments, with impeded motion of the joint, and a greater or less degree of bending of the limb; just as in gouty inflammation, swellings, and knots arise from earthy deposits. If the chronic inflammation attack the synovial membrane, earlier or later suppuration of the joint is produced, and the happiest result is *anchylosis;* but generally hectic consumption is produced.

204. Examination of the joint presents various changes in the structures affected, according to the degree and duration of the inflammation. In the more trifling form, the ligaments, and their investing cellular tissue, are thickened; subsequently they are changed into a brawny or fatty, grayish, white, yellowish or brownish mass. The synovial membrane often remains unchanged for a considerable time, or, at the utmost, has a wrinkled appearance. In the further progress of the disease, however, it is drawn into this fatlike degeneration; so that the whole of the joint presents a homogeneous mass, in which are dispersed white membranous shreds, vessels, and tendons, and not unfrequently abscesses from the size of a pea to that of a hazel nut (*a*). This mass gradually involves the healthy cellular tissue, and even extends to the muscles. If further destruction occur in the joint, all those changes take place which are alluded to in other forms of inflammation of the joints.

[Key (*b*) says, that, "in ligamentous fibre, the process of ulceration appears to be accompanied with some peculiar circumstances. The ligament, instead of preserving its usual form and size, becomes distended, and feels pulpy. When cut into, the fibres are found to be separated from each other by a vascular structure, which, upon being injected, has a villous appearance. This interstitial vascular mass is the reticular membrane, that in the healthy structure unites the ligamentous fibres; under inflammation it becomes highly vascular, and assumes the appearance alluded to, while the fibres of the ligament retain their natural glistening appearance, until, in the progress of the disease, they at length become softened and pulpy previously to their undergoing absorption. It is not

---

(*a*) Jæger; in his Handwörterbuch der gesammten Chirurgie und Augenheilkunde, Leipzig, 1836, vol. i. p. 537.

(*b*) On the Ulcerative Process in Joints; in Med.-Chir. Trans., vol. xviii. 1833.

improbable that the ligamentous fibres themselves are passive in the ulcerative process which, there is some reason for believing, is performed entirely by the vascular tissue that surrounds them." (p. 215.)

Sometimes, young people, from being compelled by their occupation to bear heavy weights, and especially from wheeling heavy barrows, have the plantar ligaments of the foot, or the inner lateral ligament of the knee, very considerably lengthened; and, as regards the lateral, that very common condition of the joint in labouring persons called knock-knees or in-knees, a very remarkable instance of which is mentioned by **Wickham**, in which "the left leg was so affected by this lateral inclination that the leg was nearly at right angles with the thigh." (p. 100.) Not unfrequently, also, are the ligaments of a joint generally relaxed, and thereby the strength of the joint greatly diminished, when large quantities of synovial fluid, produced by inflammation and long continuing, have at last been absorbed. In neither case, however, is there any actual disease of the ligament, but simply are they relaxed.—J. F. S.]

205. The causes of inflammation of the ligaments may be all the general causes already mentioned, (*par.* 199,) especially the traumatic and rheumatic in scrofulous and lymphatic persons, in whom particularly the chronic form of this inflammation is most common. It may occur in all joints, but it is most common in that of the knee and elbow.

206. The *treatment* must be guided by both the degree of the inflammation and its cause. In severe traumatic inflammation, general, but especially repeated and free local blood-letting by leeches, cold applications, and a corresponding general treatment must be employed. Perfect rest in this, as in all other forms of inflammation of the joints is absolutely necessary. In rheumatic and gouty inflammation in the slighter stages, warmth is to be applied, by rolling in flannel, woollen, and the like, and the internal use of diaphoretics, as hydrochlorate of ammonia, antimonial wine in small doses, or wine of colchicum seeds; in more severe inflammation, more active antiphlogistic treatment is called for, always, however, with caution and proper restriction. In the chronic course of inflammation, repeated blood-letting by a small number of leeches or by cupping-glasses must be employed. If rheumatism or scrofula be the ground of the disease, the internal use especially of *vinum colchici* and cod-liver oil is requisite. As the inflammation subsides, mercurial friction and repeated blisters are very advantageous.

207. If without further inflammation thickening and swelling of the ligaments and cellular tissue occur, their dispersion must be attempted by encouraging absorption, for which purpose various infrictions, fomentations, and plasters are recommended. The most efficient remedies, according to my experience, are, repeated cupping or dry cupping, rubbing in mercurial ointment either alone or with caustic ammonia and camphor, iodine ointment, proper pressure with a bandage; in suppuration, continued blisters; corresponding general treatment of the internal cause. I have not seen any particular benefit from moxas, or from the slight scoring with the actual cautery, which has been recommended.

208. If the inflammation run into suppuration on the external surface of the capsular ligament, it must, when fluctuation is distinct, be properly opened; care must be taken for the free flow of the pus, and poultices applied (1). If the suppuration attack the joint itself, and, if the simple local use of poultices and corresponding general treatment do not lead us to hope that anchylosis can be effected; if the symptoms become worse, and hectic consumption be feared, amputation, or, under favourable circumstances, removal of the carious joint ends of the bones, is the only remedy. During the treatment of the inflammation of joints, care must be taken that the

limb should be as much as possible in such position that, if stiffness and anchylosis should happen, it may be the least inconvenient; in the knee-joint, for instance, in a straight posture, but at the elbow-joint half bent (2).

[(1) The suppuration which CHELIUS here mentions, has certainly nothing to do with the ligaments, but is that

"*Disease of the cellular membrane of joints*" spoken of by WICKHAM, which has resemblance, in some respects, to the white swelling described by RUSSELL and NICOLAI, but seems to me on the whole, very different. "Inflammation," says he, "having its seat in the cellular substance, existing as a primary affection of that tissue, and continuing to occupy that part only of the joint, gives birth to a succession of symptoms wholly distinct from those which are the effect of disease, in any other part." It is first indicated by "swelling more or less, according to the situation and extent of the inflammation. If the cellular substance within the joint be affected, and the inflammation be of a chronic character, the swelling is but slight, but if that structure which invests the capsule be attacked, the swelling is very considerable, and the inflammation generally more active in its progress. The first stages of the disease, under all circumstances, are nearly the same, differing only in degree The swelling of the joint is equable and firm, and, as the skin becomes placed on the stretch, grows shining and white: this stage, which may be called the adhesive, will last sometimes for many months, and produce very great irritation on the general system." As the skin stretches more, the sensibility is much quickened, and the patient's sufferings much aggravated, so that "at times he cannot bear the weight of the bed-clothes. * * * The pain, until the arrival of this symptom, is more obtuse, and oftentimes but very slight. The duration of this stage varies very much; but the approach of that which is attended by the suppurative process, is, for the most part, marked by the usual constitutional symptoms indicating the formation of matter, such as rigors and succeeding heat, and general febrile paroxysms, which assume, if the suppuration be large, a hectic character. It sometimes happens that the constitutional disturbance is so great as to require the removal of the limb, and that before any other structure is implicated; but it is more common for inflammation to propagate itself by contiguity to the synovial membrane, and afterwards to the articulating cartilages, when it becomes confused with the peculiar symptoms attendant on disease of those parts." The disease of the cellular membrane appears in two forms: "the one in which a single, or more, spots may have been the seat of the inflammation, having its origin from some injury which the part may have received, and pursuing a chronic course to the formation of small sacs of pus in those situations, which, perhaps, ulcerate through the synovial membrane; the second case is that in which the whole of the cellular membrane, surrounding the articulation, becomes inflamed, and ultimately envelops the joint in one large abscess. The first case is the more common of the two; the latter, the effect of a sudden attack of inflammation, and more active in its course." (p. 84-6.)

In 1839, I amputated the knee of a man, aged twenty-seven years, for disease of the former kind, which had resulted from slipping down stairs and bending his knee under him sixteen months before. The examination of the joint presented a large abscess on the inner condyle of the thigh-bone, which it had flattened and somewhat roughened without laying it bare; another long abscess extending from the knee upwards behind the hamstring, and downward, about three inches, below the head of the fibula; the skin over both abscesses very thin, but neither communicating with the other, nor with an open wound above the outer condyle, the remains of an abscess which had burst five weeks before the operation. Behind the knee, in the popliteal space, was a fourth abscess, large and deep. Neither of the four had any communication with the cavity of the knee-joint, which did not contain any pus, but the synovial membrane, around the knee-cap, was thickened, soft, and jelly-like.

Earlier in the same year I saw a case of the latter kind in a woman who, about a month previous, had received a blow on the inside of the knee; a fortnight after she was attacked with severe shivering, which was followed by much swelling and puffiness about the joint, especially on the inside. A puncture was made just below the knee-cap, and twelve ounces of good pus discharged, but it was requisite to make a second opening two days after, and eight ounces more matter passed out. She did well. In a second case, where I had been attending a lady for many months, with what seemed to me chronic inflammation of the synovial membrane, with large effusion in the cavity of the joint; suppuration occurred some time after, whilst she was in Barbadoes; the abscess was opened, and she did well. Both these cases I, at the time, considered connected with the joint; but the result proved that such could not have been the case.—J. F. S.

(2) **Chelius**'s direction to keep the knee-joint straight, as the most convenient position, when there is a probability of stiffness resulting from the disease with which it is affected, is not at all satisfactory, nor should it be followed, as, thus fixed, it causes considerable halting in the gait, and, preventing the play of the ankle-joint, puts the patient in nearly the same condition as if he wore a wooden leg. And also when he sits down, the limb is obliged to thrust out before him, very inconveniently both to himself and others. The knee should, indeed, from the first of the treatment, be half bent and supported beneath by pillows, as the tendons passing over the joint, and the tendinous expansions connected with its capsule are thereby relaxed; and, if permanent stiffness take place, the bent position is most convenient for sitting; and, in walking, the play of the ankle-joint is so increased that the halting is comparatively trifling, and the patient's movements much more free than if straight. The bent position is obviously best for persons accustomed to ride on horseback. For these reasons, therefore, the bent is preferable to the straight position of the knee and leg.—J. F. S.]

B.—OF INFLAMMATION OF THE SYNOVIAL MEMBRANE.

209. *Inflammation of the Synovial Membrane* (*Inflammatio Membranæ Synovialis*, Lat.; *Entzündung der Synovialhaut*, Germ.; *Inflammation de la Membrane Synoviale*, Fr.) may arise either as a primary disease, or may have extended from other tissues. The synovial membrane is frequently attacked with inflammation on account of its vital relations; it has generally a tedious course, and the functions of the joint are not at the onset entirely destroyed.

[The importance of every circumstance connected with diseases of joints, and the difference of opinion in regard to the special structure in which one or other of them commences, and by which they are sustained, is sufficient warrant for giving some account of their natural structure and condition. And for this reason I shall here notice

The Structure of Synovial Membrane.—The first satisfactory mention of it is that of **William Hunter** (*a*); a careful perusal of which will show that very little has been really added by modern writers to his observations.

"We are told by anatomists," says this able teacher (*b*), "that cartilages are covered with a membrane named *perichondrium*. If they mean the cartilages of the ribs, larynx, ear, &c., there, indeed, such a membrane is very conspicuous; but the *perichondrium* of the smooth articulating cartilages is so fine and firmly traced upon the surface that there is room to doubt whether it has been often demonstrated or rightly understood. This membrane, however, I have raised in pretty large pieces, after macerating, and find it to be a continuation of that fine smooth membrane (the synovial membrane) that lines the capsular ligament, folded over the end of the bone, from where that ligament is inserted. On the neck of the bone, or between the insertion of the ligament and border of the cartilage it is very conspicuous, and may be pulled up with a pair of pincers; but where it covers the cartilage it coheres to it so closely that it is not to be traced in the recent subject without great care and delicacy. In this particular it resembles that membrane which is common to the eyelids and the fore part of the eyeball, and which is loosely connected with the albuginea, but strongly attached to the cornea." (p. 516.)

This observation of **William Hunter**'s in regard to the continuity of the synovial

---

(*a*) I am not aware it is generally known that **William Hunter** was not only a surgeon, but also a member of the Court of Assistants of the Corporation of Surgeons of London. I became accidentally acquainted with this fact last year, in looking over the Court Books of the Corporation, where is the following entry:—"1st July, 1756. It having been reported to the Court that Dr. **William Hunter**, a member of this Court, was desirous of being disfranchised on such terms as the Court would agree on, It was Ordered that the clerk do deliver him the instrument of disfranchisement, under the seal of this Corporation, on his paying down forty guineas for the same, being the same terms on which it was granted to Dr. **Wathen**, on the 6th Dec. 1753."—**William Hunter** took the degree of M.D. in the University of Glasgow, 24th October, 1750, and he became a Licentiate of the College of Physicians in London, in the year 1756; but at the time of his writing this, as well as other valuable papers, he was a surgeon; and it is too honourable a distinction for the Corporation of Surgeons to have included amongst its members two such celebrated men as **William** and **John Hunter**, as to pass over without its being distinctly recorded.—J.F.S.

(*b*) Of the Structure and Diseases of Articulating Cartilages; in Philos. Trans. vol. xlii. 1743.

membrane over the cartilage of joints, has been confirmed by Henle (*a*), who says:—"The epithelial layer on the inner surface of the synovial membrane attains a thickness of 0,006‴—0,008‴. Many layers of cells are here observed piled on each other, and the outermost, viz. those next the free surface, are like those in the epidermis of the cutis and mucosa, broad, flat, and of irregular form; their nucleus is not always distinct. The round cells of the synovial membrane have, in the mean, a diameter of 0,004‴—0,005‴, and the oblong cells measure as much in their smallest diameter. The ligaments and cartilages which pass through the cavity of a joint, have a covering of epithelium which is continued in a thin layer upon the joint surfaces of the cartilages, but separated from the cartilage corpuscles by a thin layer of cellular tissue." (p. 116.)

Toynbee (*b*) also states that, "in a fœtal calf, towards the latter part of uterine existence, he had removed the synovial membrane from nearly the entire surface of the articular cartilage of the condyle of the femur, to which it was attached by a considerable layer of cellular tissue in which the blood-vessels are seen to ramify." (p. 167.) These are not, however, as he supposes, the branches of William Hunter's *circulus articuli vasculosus*, which, as we shall hereafter see, are described by him "as creeping around the cartilaginous brim, or *under* the cartilage," for especial reasons; but Toynbee himself properly describes them as "the vessels of the synovial membrane which cover the articular cartilage," and says that "during fœtal and infantile life, previous to the period when the articular cartilages are subject to pressure, the synovial vessels extend over certain portions of them, from which, in childhood and during adult age, owing to the functions of the joints, they are necessarily absent. At the period when the child begins to use the various joints, and subjects them to pressure, these vessels recede, and in adult life they are only found on that margin of articular cartilage which is exempt from the influence of external forces. The arteries which pass between the articular cartilage and the synovial membrane, like those of the fœtus, may be considered as the termination of the articular arteries. At the point where the reflexed become continuous with the articular synovial membrane, it contains large vessels subjacent to it which are numerous and plexiform. Immediately, however, that they enter the cellular web, between the articular cartilage and synovial membrane, they become enlarged and straight, and pass to a greater or less distance over the border of the articular cartilage, forming loops, frequently with considerable dilatations, and becoming finally continuous with the veins. The free surface of adult cartilage appears to be nourished by the *liquor sanguinis* which exudes from these looped and dilated vessels." (pp. 172, 3.) I doubt the correctness of Toynbee's statement of the recession of the vessels when the child begins to use his joints, and consider that the analogy with the conjunctive coat of the eyeball here also holds good, and, as there, under ordinary circumstances, its vessels are not seen, as they then carry only colourless blood, yet under inflammation they appear numerous and loaded with red blood; so also the same condition is that of the vessels of synovial membrane. Before concluding this short notice regarding the synovial membrane, I would mention Clopton Havers' (*c*) opinion, that the "soft parts, found in the sinuses of the bones within the joint, which to the touch seemed vesicular and spongious, and the membrane not only lax, but also unequal, with protuberances of a different figure and magnitude," were, the latter, "truly glandulous, and those soft bodies, glands." He applied to them the name of "glandulæ mucilaginosæ, or the mucilaginous glands." (pp. 188, 89.) After giving an account of their structure and vascularity, he speaks of their form as "various, and accommodated to the sinus or cavity in which they are seated. Some are not only long but broad at their top, and grow narrow towards the top, so as to terminate in an edge; some have a broad basis, and rise into a sort of cone; some are like little ridges, some like a fimbria, some are broad and pretty flat;" and then observes on their situation, that "in general they are so seated that they cannot be injured by a compression from the bones." (pp. 193, 4.) Goodsir (*d*), in referring to them, says:—"I have been in the habit of considering the highly vascular fringes and processes of the synovial membranes as more active in the formation of epithelium, and therefore more closely allied to the secreting organs than other portions of these membranes. If this be the case, Clopton Havers was not mistaken in his ideas regarding the functions of these vascular fringes. They are situated where they cannot interfere

---

(*b*) Researches tending to prove the non-vascularity and the peculiar uniform mode of organization and nutrition of certain animal tissues, viz. Articular Cartilage and the Cartilage of the different classes of Fibro-Cartilage, &c., &c.; in Phil. Trans., 1841.

(*c*) Osteologia Nova; or some New Observations of the Bones, &c. London, 1691. 8vo.

(*d*) On the Structure of the Serous Membranes; in his Anatomical and Pathological Observations. Edinburgh, 1845. 8vo.

with the motions of the joint. They hang into those parts of the cavity best fitted for containing and acting as reservoirs of synovia; and their high vascularity, and the pulpy nature of their serous covering, tend to strengthen this opinion." (pp. 42, 3.)

That **Havers'** opinion is correct as to the function of these vascular fringes, I think there is not a doubt, having had to-day (May 2, 1845) the pleasure of being shown, by my laborious friend **Rainey**, our microscopist at St. Thomas's museum, their minute structure on the synovial membrane of joints and in tendon sheaths, which, he tells me, he made out and showed to our mutual friend **Grainger** at least eighteen months since, although, till the present time, it has not been made public. He demonstrates the vessels contained in the fringes as having a very different disposition from those secreting fat, and, being surrounded by an investment of epithelium, from which it is evident that the old idea of their being the synovial glands is correct, and that the modern notion of their being fat-vessels, held by some physiologists, is incorrect. Moreover, that when the sheath, at least of an adult tendon, is injected, these organs are the only parts which readily receive the injection, and appear like vascular lobules on a whitish ground, the other parts of the sheath scarcely exhibiting any injection.—J. F. S.

"No part of the body," says **Brodie**, "is much more frequently diseased than the synovial membranes. This is what their anatomical structure and functions might lead us to expect, since we find that living organs are more subject to have their natural functions deranged, in proportion as they are more vascular, and as they are employed in a greater degree in the process of secretion." (p. 8.)]

At the beginning the pain is trifling, and, although affecting the whole joint, is more severe at one part. Frequently, however, it is very violent, motion of the joint is impossible, and fever occurs. After some time swelling comes on, which fluctuates differently, according to the form of the joint, and is more evident at those points where the soft parts afford least resistance. If the inflammation be long continued, or recur frequently, the swelling becomes gradually larger and harder, depending on the loosening and hardening of the synovial membrane and ligaments; severe pain, sleeplessness, and hectic fever come on; the swelling bursts at different parts, and the powers of the patient are exhausted. In the most favourable cases anchylosis takes place. If the inflammation be very insidious, and do not go on to loosening of the synovial membrane, it may terminate in dropsy of the joint and weakening of the ligaments; so, when the inflammation specially affects the ligaments, thickening of them, with impeded motion and greater or less bending of the joint, swellings, and knots from deposition of earthy matter, (especially in gouty inflammation,) may occur.

[**Chelius** here considers as one, the two forms of diseased synovial membrane which have been distinguished by **Brodie**; the one as "consisting simply in a morbid action," and the other, or "others, in which the morbid action produces a morbid change of anatomical structure." (p. 76.) The former, arising simply from common inflammation, which may be resolved entirely, or terminate in one or other of the usual consequences of inflammation, or which may degenerate into the second form, in which a specific change of structure takes place. It will, therefore, be necessary to point out these different forms.—J. F. S.

Common inflammation of the synovial membrane may be either acute or chronic, or it may assume the sub-acute form, which is by far the most frequent, and generally passes by the name of chronic inflammation.

As to the comparative occurrence of synovial inflammation, **Brodie** observes:—"Although no period of life is altogether exempt from this disease, it does not occur equally in persons of all ages. It very seldom attacks young children, becomes less rare as they approach the age of puberty, and is very frequent in adult persons. This is the reverse of what happens with respect to some of the other diseases to which the joints are liable, and a knowledge of these circumstances will be found of some importance to the surgeon, in assisting him to form a ready diagnosis." (p. 20.)

Acute synovial inflammation may arise spontaneously, but mostly it results from injury as either blows or wounds. When it occurs, **Brodie** observes, that "the swelling takes place immediately after, or at the same instant, with the first attack of pain; there is redness of the skin; the pain is more severe, and it is so much aggravated by the motion of the parts, that the patient keeps the joint constantly in the same position, and usually in an intermediate state between that of flexion and extension. In addition to these symptoms, there is more or less of symptomatic fever of the inflammatory kind. In a few days, the disease, if left to itself, assumes the chronic form, or, perhaps, under proper treatment, it subsides altogether. It must be observed, however, that the boundaries of acute and chronic inflammation do not admit of being very well defined. These terms accurately enough express the two extremes; but there are numerous intermediate degrees of inflammation, of which it is difficult to determine whether they should be considered as being of the acute or chronic kind." (pp. 31, 2.)

Sometimes the inflammation runs on to *suppuration*, and the constitutional excitement is more or less severe till the pus have either found its way out by ulcerating through the whole wall of the joint, or till it have been discharged by puncture; but in either case it sometimes proves fatal from the disturbance produced. The following are examples:—

CASE 1 is mentioned by BRODIE:—"A young lady, nine years of age, being at play on the first of January, 1808, fell and wrenched her hip; she experienced so little uneasiness that she walked out on that day as usual. In the evening she went to a dance, but while there, was seized with a rigor, was carried home, and put to bed. Next morning she was much indisposed, and complained of pain in the thigh and knee: on the following day she had pain in the hip, and was very feverish. These symptoms continued; she became delirious, and she died just a week from the time of the accident. On inspecting the body on the following day, the viscera of the thorax and abdomen were found in a perfectly healthy state. The hip-joint on the side of the injury contained about half an ounce of dark-coloured pus; and the synovial membrane, where it was reflected over the neck of the former, was destroyed by ulceration for about the extent of a shilling." (pp. 73, 4.) BRODIE mentions this as a case of "ulceration of the synovial membrane, as a primary affection;" but it seems to me rather the result of the pressure of the pus in attempting to produce an outlet. And I think that his other case, in which there was "about half an ounce of thin pus found in the shoulder-joint; and the synovial membrane bore marks of general inflammation, and in one spot where it was reflected over the neck of the *os brachii* was destroyed by ulceration for about the extent of a sixpence," (p. 75,) was under similar though less urgent circumstances.—J. F. S.

CASE 2 is related by WICKHAM, in which the pus was discharged by ulceration, but the girl died. M. C., aged fifteen years, applied to him, "on account of pain which she had for several days experienced in her left knee-joint; at that time it had not been severe, but it was confined to one spot below the patella, and she described it as of a dull aching kind." Leeches, saturnine lotion, and aperient medicine were ordered. Three days after she was "suffering very greatly; the pain was general over the joint, of the tensive character, and the part swollen to nearly double its natural size. The skin over it was hot and shining; the febrile symptoms were very high, and delirium had come on. Six days after, suppuration had established itself; and, after the lapse of eleven days more, "she died without any mitigation of the constitutional disturbance; the sensorium continuing to be affected to the last." (pp. 68, 9.)

CASE 3.—In this instance the abscess was opened, and ultimately did well. In 1836, E. A., a girl of twenty-two years of age, slipped down stairs, and wrenched her knee, but so slightly, that she took no notice of it till a week after, when she had pain at the top of the knee, which increased so much during a single night, that on the following day she was unable to put her foot to the ground, on account of the severity of the pain. She continued suffering severely for three weeks, and then came to the hospital, the girth of her knee being twenty-two inches: fluctuation was very distinct all round the knee-cap; she was free from pain when at rest, but if moved, pain came on, and was increased if the leg hung down. Leeches, blisters, and an issue were employed, but without benefit. The tumefaction increased, and the neighbouring cellular tissue on the thigh became œdematous. She continued during five weeks getting worse, and, the skin thinning, a lancet was passed in, which evacuated eight ounces of pus, and the wound, having been carefully closed, healed up. But the matter continued to form, and the pain increasing, and the joint having acquired its former size, another puncture was made, and half a pint more pus escaped. The wound was left unclosed, the discharge continued, but in the course of a fortnight pain, even on motion ceased, and she slowly recovered.

When the synovial membrane suppurates after wound of the joint, very commonly the whole of its interior is destroyed, and the patient is worn out, unless the limb be amputated; or under favourable circumstances the patient recovers with a stiff joint.

If the acute stage be checked, it sometimes subsides entirely, but at other times the inflammation becomes chronic, or terminates in the effusion of a large quantity of fluid in the cavity.

In the much more frequent *subacute or chronic form*, when "inflammation of the synovial membrane takes place, as a symptom of constitutional affection, where the system is under the influence of gout or rheumatism, &c.," BRODIE says, "in these cases, the disease, for the most part, is not very severe; it occasions a preternatural secretion of synovia, but does not, in general, terminate in the effusion of coagulable lymph, or in thickening of the inflamed membrane. Sometimes it attacks the greater number of the joints at the same instant, and even extends to the synovial membranes, which constitute the *bursæ mucosæ* and sheaths of the tendons. At other times, it leaves one part to attack another, and several joints are affected in succession. In other cases, the disease is entirely local, produced by a sprain, or other injury, or the application of cold, and sometimes arising from no evident cause. * * * Where the inflammation is thus confined to a single joint, it is more probable that it will assume a severe character, and that it may be of long duration. It leaves the joint with its functions more or less impaired, and occasionally terminates in its total destruction. In itself it is a serious disease; but it is often confounded under the alarming name of white swelling, with other diseases, which are still more serious." (pp. 21, 2.)

"The pain," BRODIE observes, "usually continues to increase during the first week or ten days, when it is at its height. Sometimes even at this period the pain is trifling, so that the patient experiences but little inconvenience from it: at other times it is considerable, and every motion of the joint is distressing and difficult. In the course of one or two days after the commencement of the pain, the joint may be observed to be swollen. At first the swelling arises entirely from a preternatural collection of fluid in its cavity. In the superficial joints, the fluid may be distinctly felt to undulate when pressure is made alternately by the two hands placed one on each side. When the inflammation has existed for some time, the fluid is less perceptible than before, in consequence of the synovial membrane having become thickened, or from the effusion of lymph on its inner or outer surface; and, in many cases, where the disease has been of long standing, although the joint is much swollen, and symptoms of inflammation still exist, the fluid in its cavity is scarcely to be felt. As the swelling consists more of solid substance, so the natural mobility of the joint is, in a great degree, impaired." (p. 23–5.)

"Inflammation may attack the synovial membranes in different degrees of intensity; but, for the most part, it has the form of a chronic or slow inflammation, which, while it impairs, does not altogether destroy the functions of the joint; and which, if not relieved, in the first instance, by active and judicious treatment, may, like a chronic ophthalmia, continue for weeks or months, and, with occasional recoveries and relapses, may even harass and torment the patient during several successive years." (p. 23.)

"The form of the swelling deserves notice. It is not that of the articulating ends of the bones, and, therefore, it differs from the natural form of the joint. The swelling arises chiefly from the distended state of the synovial membrane, and hence its figure depends, in great measure, on the situation of the ligaments and tendons, which resist it in certain directions, and allow it to take place in others. Thus, when the knee is affected, the swelling is principally observable on the anterior and lower part of the thigh, under the extensor muscles, where there is only a yielding cellular structure between those muscles and the bone. It is also often considerable in the spaces between the ligament of the patella and the lateral ligaments; the fluid collected in the cavity causing the fatty substance to protrude in this situation, where the resistance of the external parts is less than elsewhere. In the elbow, the swelling is principally observable in the posterior part of the arm, above the olechranon, and under the extensor muscles of the fore arm. And in the ankle, it shows itself on each side, in the space between the lateral ligaments and the tendons, which are situated on the anterior part." (pp. 25, 6.)

"After inflammation of the synovial membrane has subsided, the fluid is absorbed, and, in some instances, the joint regains its natural figure and mobility; but, in other cases, stiffness and swelling remain. Sometimes the swelling has the same peculiar form which it possessed while the inflammation still existed, and while fluid was contained in the joint; and we may suppose that it depends principally on the inner surface of the synovial membrane having a thick lining of coagulable lymph; at other times, the swelling has the form of the articulating extremities of the bones, that is, nearly the natural form of the joint, and it probably arises from the thickened state of the synovial membrane. * * * In those cases where the synovial membrane is thickened, although the fluid which had been effused is absorbed, and the principal swelling has disappeared, it occasionally happens, not only that a certain degree of inflammation still lingers in the part, but that it continues until the morbid action extends to the other textures, and ultimately ulceration takes place in the cartilages, suppuration is established, and there is complete destruction of the articulating surfaces." (p. 28, 9.)

"With respect to the fluctuation," LAWRENCE (*a*) says, "that cases of this kind differ materially. In some instances the tumefaction of the joint is quite soft, and we can very easily detect the fluid: we can move it from one part to another: by pressing on the tumour above, we elevate the patella from its situation, actually lift it up from the trochlea of the os femoris, and then, by pressure upon it, can push it down again into a sort of cavity. In some cases the swelling feels much harder; and there are cases, where the inflammation is violent and has proceeded rapidly, in which the swelling is so firm as to afford but a slight sensation of tumefaction to the hand. I have seen cases which, from the tension produced by the large quantity of fluid, have quite deceived me, and have presented all the characters of a solid tumour. However, on cautiously examining those cases, more particularly if the knee is put as much as possible into the extended state, so as to relax the extensor muscles, you will be able to detect the nature of the tumour, although at first it may give you the impression that it is solid." (p. 480.)

Not very unfrequently, I think, though BRODIE says "not often * * * a joint is swollen from a preternatural quantity of fluid collected in its cavity, without pain or inflammation. This may be supposed to arise, either from a diminished action of the absorbents, or an increased action of the secreting vessels. The disease may be compared to the dropsy of the peritoneum or pleura, or, more properly, to the hydrocele; and it has been not improperly designated by the terms *Hydrarthrus* and *Hydrops Articuli.*" (p. 10.)

Here would seem to be the most convenient place to mention the alleged differences between inflammation of the ligaments, and that of the synovial membrane; and, though the form specially mentioned is that of *rheumatic inflammation*, and it might be more strictly considered to belong to the physician's department, yet, as it is the only attempt made to distinguish between the inflammatory conditions of the two tissues, I shall make no apology for the following long extract from WATSON (*b*):—"There are two varieties of acute rheumatism, a circumstance first noticed by Dr. CHAMBERS at St. George's Hospital, and afterwards made public by Dr. FRANCIS HAWKINS in his Gulstonian Lectures. The varieties are spoken of under the names of *fibrous* or *diffused* rheumatism, and *synovial* rheumatism. I apprehend, however, that in both of them the inflammation has its starting point in some fibrous texture; but that in the one a considerable extent of that texture is implicated, while the inflammation does not involve the neighbouring synovial or serous tissue; and in the other the extent of fibrous tissue affected in the onset is comparatively small, while the local symptoms are more expressive of the secondary synovial disease. I will briefly state the distinctive characters of these two varieties of what is primarily and essentially the same malady. In the one, then, the inflammation commences in the immediate neighbourhood of one of the larger joints; not *in* the joint, but *near* it. It attacks the tendons, fasciæ, ligaments, and possibly also the muscles. There is not, at first, much redness or swelling; but after the pain has been of some duration, there is a puffiness around the parts affected, caused apparently by turgescence of the blood-vessels, and at length slight pitting or *œdema* may supervene, from effusion into the surrounding cellular tissue, and what redness is present is disposed in streaks, following the course of the tendons. On the other hand, in the synovial variety, which shows itself more frequently and more plainly in the knee than any where else, the pain, which marks the onset of the complaint, does not last long before some degree of swelling is perceptible, together, in most instances, with slight redness of the skin; and this swelling is not due so much to turgescence of vessels as to œdema of the cellular tissue, as to fluid poured into the *cavity* of the joint. And the form and character of the swelling indicate that it is the result of the fulness and distension of the synovial membrane; it is tight and elastic, and protrudes, as it were, through the spaces that intervene between the tendons and the ligaments, by which it is in other parts bound down and restrained; and *fluctuation* is often distinctly perceptible in the superficial joints, when both hands are applied to them. These are the *local* differences between the two forms of the disease. And there are differences equally well marked between the constitutional symptoms that attend them. It is in that form which (*κατ' ἐξοχην*) is called *fibrous* rheumatism, that the inflammatory fever runs so high, that the tongue is so thickly furred, that the round full-bounding pulse occurs, that the profuse spontaneous acid perspirations break out, which exhaust the patient's strength without alleviating his sufferings, that the urine is high coloured, and deposits a copious sedi-

(*a*) Lectures in Lancet, 1829–30, vol. ii.

(*b*) Lectures on Physic, vol. ii.

ment like brickdust. In the *synovial* form, the fever is either less intense from the beginning, or soon moderates, after the joints begin to swell; the tongue is less foul; the patient sweats much less. It is to this form that the term *rheumatic gout* is often applied." (pp. 621, 2.) Of the chronic rheumatism WATSON also mentions two kinds:— "One attended with local heat and swelling, although the constitution at large sympathises very little, or not at all, with the topical inflammation; the other characterized rather by coldness and stiffness of the painful joints. In the former of these, the pains are increased by pressure, and by movements of the limbs, and by external warmth, the warmth of a bed for example; and there may be even some slight degree of pyrexia at night. In truth, this form of chronic rheumatism claims a near relationship with the acute, *into* which it sometimes passes, and *of* which it is frequently the sequel." (pp. 628, 9.)

Gonorrhœal Rheumatism and *Gonorrhœal Ophthalmia* were, I believe, first mentioned publicly by ASTLEY COOPER, and "the first of these affections," he considers, "is not an unfrequent disease;" but it appears to have been previously observed by the elder CLINE; for, in reply to the question put to him by COOPER, Whether he had ever seen rheumatism produced from gonorrhœa? he said:—"Several times." COOPER'S account of the disease is described in his usual homely but graphic manner, in the following, his first

CASE.—"An American gentleman came to me with a gonorrhœa, and, after he had told his story, I smiled and said, 'Do so and so,' particularizing the treatment, and that he would soon be better, but he stopped me and said, 'Not so fast, sir; a gonorrhœa with me is not to be made so light of; it is no trifle; for in a short time you will find me with inflammation in the eyes, and in a few days after I shall have rheumatism in the joints. I do not say this from the experience of one gonorrhœa only but from that of two, and on each occasion I was afflicted in this manner.' I begged him to be careful to prevent any gonorrhœal matter coming in contact with the eye, which he said he would. Three days after this I called on him, and he said, 'Now you may observe what I told you a day or two ago is true.' He had a green shade on, and there was ophthalmia of each eye. * * * In three days more he sent for me rather earlier than usual, for a pain in his left knee; it was stiff and inflamed. I ordered some applications and soon after the right knee became affected in a similar manner. The ophthalmia was with great difficulty cured, and the rheumatism continued many weeks afterwards. * * * Whether it is by absorption of the poison or the constant irritation produced by the inflammation of the urethra, I do not know; but certain it is that gonorrhœa produces ophthalmia and rheumatism, and when not a single drop of matter has been applied to the eye. The inflammation generally attacks both eyes and is of long duration." (pp. 273, 4.)

BRODIE also speaks of cases of inflamed synovial membrane after gonorrhœa; these were in every instance accompanied with purulent ophthalmia, which, in most, but not in all, preceded the affection of the joints, which recurred often, again and again; and in one case the joint was affected nine times.

For our knowledge of that form of diseased synovial membrane, which may be called *pulpy degeneration*, we are indebted to BRODIE, who describes it as consisting "in a morbid alteration of structure, which takes place in the synovial membranes of joints, and which, as far as I have seen, is peculiar to these parts. I have never known an instance of the same diseases in the serous membranes, which so nearly resemble the former in their nature and functions; nor even in the synovial membranes that constitute the bursæ mucosæ and sheaths of the tendons." (p. 77.) The disease seems to commence in the reflected portions of the synovial membrane, converting them into a light brown pulpy substance, varying from a quarter to a half, or even a whole inch in thickness, intersected with white membranous lines and red spots, formed by small vessels injected with their own blood. It then attacks the synovial membrane, which over-spreads tke cartilaginous covering of the ends of the bones, beginning at their edge and extending gradually over them, ulceration in those cartilages going on correspondently, till the carious or ulcerating surfaces of the bone are exposed. The cavity of the joint sometimes contains pale yellow fluid in the floating flakes of lymph, or pus, which is discharged externally by ulceration; but sometimes neither. Or abscesses may exist in the altered synovial membrane itself, without communication in the joint. LAWRENCE says, that "the ligaments, perhaps, are free from disease, and so, perhaps, are the cartilages; at all events, if either are affected, it will be the cartilages:" (p. 482:) on this point, therefore, he does not agree with BRODIE. The latter author considers that this disease "belongs to the same order with tubercles of the lungs, scirrhus of the breast, the medullary sarcoma or fungus hæmatodes of the testicle, and numerous other diseases, in which the natural structure of the affected organ is destroyed, and a new and different structure is added in its place. To these also it bears a near resemblance in its progress. Thus tubercles of the lungs, in the first instance, occupy the vesicular and interlobular substance; but ultimately they inflame and ulcerate, abscesses form in them, and the pleura, the bronchia, and other contiguous parts become affected. * * * In every case in which I have had it in my power to watch its progress, the complaint has advanced slowly, and sometimes has remained in an indolent state during a very long period, but ultimately it has always terminated in the destruction of the joint. It is a remarkable circumstance that this affection of the synovial membrane is rarely met with, except in the knee. I have never known an instance of it in the hip or shoulder. But Hodgson of Birmingham informs me he has met with one example in the ankle, and another in one of the joints of a finger." (p. 95–7.)

If by placing this disease in "the same order with tubercles of the lungs, scirrhus of the breast," &c., Brodie means to infer that it is malignant in the usual acceptation of the term, I must differ from him, as I am not aware that it presents itself in any other organ of the body, and, indeed, he himself observes, "it is a remarkable circumstance that this affection of the synovial membrane is rarely met with except in the knee." It destroys life, indeed, if the limb be not removed; but only in the same way as other causes by which the surface of the joint is destroyed and either opened or not, by wearing out the powers of the constitution.— J. F. S.

"This disease," according to Brodie, "generally takes place in persons who are not much above the age of puberty. I do not recollect," says he, "one instance of it having occurred after the middle period of life. In general it can be traced to no evident cause; but occasionally it is the consequence of repeated attacks of inflammation. In this respect it resembles other diseases of the same order. Inflammation of the lungs may lay the foundation of tubercles, and inflammation of the breast may occasion the growth of a scirrhous tumour. * * * In the origin of this disease there is a slight degree of stiffness and tumefaction, without pain, and producing only the most trifling inconvenience. These symptoms gradually increase. In the greater number of cases, the joint at last scarcely admits of the smallest motion; but, in a few cases, it always retains a certain degree of mobility. The form of the swelling bears some resemblance to that in cases of inflammation of the synovial membrane, but it is less regular. The swelling is soft and elastic, and gives to the hand a sensation as if it contained fluid. If only one hand be employed in making the examination, the deception may be complete, and the most experienced surgeon may be led to suppose that there is fluid in the joint when there is none; but, if both hands be employed, one on each side, the absence of fluid is distinguished by the want of fluctuation. The patient experiences little or no pain until abscesses begin to form and the cartilages ulcerate; and, even then, the pain is, in many instances, not so severe as where the ulceration of the cartilages occurs as a primary disease, and the abscesses heal more readily, and discharge a smaller quantity of pus, than in cases of this last description. At this period the patient becomes affected with hectic fever, loses his flesh, and gradually sinks, unless the limb be removed by an operation. * * * The gradual progress of the enlargement and stiffness of the joint without pain, and the soft elastic swelling without fluctuation, in the majority of cases, enables us to distinguish it readily from all the other morbid affections to which the joints are liable. The cases with which those of this disease are most liable to be confounded are those of chronic inflammation of the synovial membrane. *Firstly.* When the synovial membrane has undergone a morbid change of structure, it occasionally happens that a preternatural secretion of fluid takes place at the same time from its inner surface, and the joint becomes distended, not with synovia, but with a turbid serum, having flakes of coagulable lymph floating in it, which causes the tumour to present nearly the same external characters as where synovial membrane is inflamed." But Brodie distinguishes it by its not yielding to the ordinary treatment, and by the accurate previous history. "*Secondly.* When the synovial membrane, after inflammation has subsided, has been left in a thickened state, and coagulable lymph has been effused into the articular cavity, the tumour, in some instances, a good deal resembles the tumour which occurs in cases of this disease; so much so, that it will be very difficult to give a correct opinion merely from observing the present appearance and condition of the joint. The surgeon must, in great measure, form his judgment from the account which he receives of the origin and early symptoms of the complaint, or, when an accurate statement cannot be procured, by waiting to observe its future progress." (p. 101–6.)]

210. The examination of the joint after death shows, in a milder form of the disease, the synovial membrane inflamed, and the cavity of the joint

filled with a thin, often reddish, fluid (1). In a more advanced state, thickening of the ligaments, swelling of the synovial membrane into a fungous fleshy-like mass penetrated with white streaks, often with a mass beset with polypous or hydatid-like growths, a collection of yellowish lymph mixed with white flakes (2); finally, destruction of the cartilages and caries of the joint ends of the bones (3).

[(1) This is the result of simple inflammation. BRODIE mentions one excellent example, in which, "throughout the whole of its internal surface, except where it covered the cartilages, the synovial membrane was of a dark-red colour; the vessels being as numerous and as much distended with blood as those of the *tunica conjunctiva* of the eye in a violent ophthalmia." (p. 12.) In another case—"the synovial membrane was increased in thickness about one-eighth of an inch, and was of a gristly texture." (p. 14.) The former patient had died of fever, independent of the disease in the knee-joint; and the limb of the latter was removed for some other complaint. These are highly important cases, as opportunities for examining inflamed synovial membrane in this, its primary condition, are very rare.

(2) This is the pulpy degeneration described by BRODIE.

(3) This appears to me the form of joint disease described by KEY (*a*), in which "the cartilage is not absorbed *per se*, but through the agency of a structure probably evolved for the special purpose of completing that process," (p. 134,) or, as he elsewhere (*b*) expresses it, a "highly vascular fringe of (synovial) membrane, which is a newly organized, and, in some parts, a superadded structure for the purpose of producing ulceration of the contiguous cartilage." (p. 224.) I fully concur with the correctness of KEY's views upon this point, having seen the condition he describes again and again. But it will be more convenient to consider the subject in connexion with true ulceration of cartilage, a little further on.—J. F. S.]

211. The inflammation of the synovial membrane occurs very readily in superficial joints, especially in the knee-joint, from mechanical violence, cold, rheumatism, gout, gonorrhœa, syphilis, or improper use of mercury. It takes place frequently in several joints at once, or in one after another. When arising from some marked internal cause, the course of this inflammation is usually tedious.

212. The prognosis is more favourable when the disease is consequent to external than when it depends on internal causes. At first it can be dispersed by proper treatment; subsequently, when a collection of fluid has taken place, the resolution is only slowly brought about, and there remains for a long while, and often permanently, a swelling of the joint. If the synovial membrane and the ligaments be much thickened or ulcerated, the cartilages and bones affected, and openings of abscesses present, anchylosis must be considered the most favourable termination: in the majority of cases, however, the removal of the joint is the only remedy.

213. The *treatment* is guided by the causes and degree of the inflammation. If the affection of the joint be connected with general disease, the plan of cure must be directed towards it. In rheumatism and gout especially, *vin. sem. colch.*; in scrofula, cod-liver oil; in gonorrhœa and syphilis, ZITTMANN's decoction. In more severe degrees of inflammation, general, but especially repeated local blood-letting with leeches, and cold fomentations with lead wash are required; but warm fomentations or soothing poultices when the swelling is considerable. When the course of the inflammation is slow, cupping at the commencement is sufficient.

[As regards the local treatment of simple acute inflammation of the synovial membrane, BRODIE says, "If the swelling has rapidly risen to such a height as to occasion considerable tension of the soft parts, the pain will be best relieved by means of warm fomentations and poultices; but otherwise cold evaporating lotions seem to produce a

---

(*a*) Med.-Chir. Trans., vol. xix.

(*b*) Med.-Chir. Trans., vol, xviii.

better effect." (p. 35.) I must confess in these cases I prefer warm poultices, either of bread or chamomile flowers, or hot flannels frequently reapplied: the warmth having appeared to me most soothing in the majority of cases. But, as sometimes cold, sometimes heat, affords ease to patients of different constitutions, their feelings must be attended to, and either treatment, found most agreeable, continued. The subacute inflammation requires leeching more frequently, and sometimes cupping; but I think leeches are preferable, as the wounds they make often excite a little erythematous inflammation on the skin, which acts as a gentle diversion. Warm applications here also seem to me preferable to cold. Blisters should not generally be employed till blood has been taken from the part twice or thrice, and the tenderness is either subsiding or has subsided. But sometimes they may be needed earlier if the constitution be weakly and the patient cannot bear the loss of blood.

If the simple acute inflammation of the synovial membrane terminate, as it sometimes does, in suppuration, the swelling should be punctured and the pus discharged as soon as it points, or, perhaps, even before, as the severity of the constitutional excitement will lead to a tolerably sure diagnosis of its existence. The longer it is retained the more does the constitution suffer, and the greater is the liability of ulceration of the membrane and cartilages. There is but a choice of evils, and that of opening the joint seems, to me, less than that of the continued confinement of the pus. I do not think blisters in this case are of much use.—J. F. S.]

214. When the inflammatory stage has passed, but the swelling (from effusion of fluid into the joint) continues, the dispersion is to be encouraged by blisters, repeated around the whole joint, or applied in the neighbourhood, or kept open for some sufficient time with savine cerate; by rubbing in mercurial ointment with camphor and caustic ammonia, by application of solution of acetate of ammonia, by stimulating and dispersing plasters, as *emp. ammon. c. acet. scill.*, and so on. The stiffness in the joint, which often is long continued, may be removed by rubbings with volatile substances, by baths, douche, and careful motion.

[For the removal of fluid in the joint I believe that blisters are the most efficient remedy we can employ; but I do not like blistering the whole joint at once, nor dressing blisters with savine ointment, as, in the one case, independent of strangury which is sometimes excited, and is very annoying as well as painful, it is requisite to wait till the sore is healed before a second application can be made; and, as regards the savine ointment, the pain it causes, if properly applied, (*i. e.*, immediately to the cutis, the cuticle having been previously removed,) is extremely severe, and, as I think, not warrantable by the benefit obtained. I therefore prefer the employment of repeated blisters, two at a time, each about as large as a crown-piece, one above and the other below and on opposite sides of the joint, applied on the alternate parts every third day, by which time, generally, the first applied blisters are beginning to heal, if, immediately after they have risen, they be punctured, and either poulticed or dressed with simple ointment. In this way a constant diversion on the skin may be kept up to an almost unlimited period, with little actual inconvenience to the patient, but with remarkable benefit to his joint. Or, each side of the joint may be alternately blistered, and, the cuticle having been removed, may be dressed with the ointment of iodide of potass, a drachm to the ounce, which is often very efficacious.—J. F. S.

In reference to friction, which was formerly more in vogue than at present, and, if properly employed, is very useful in cases of stiffness after the absorption of the fluid, Brodie very justly observes:—"It should be employed with caution, as, when used too freely, it sometimes occasions a return of the inflammation. Whenever there is the slightest indication of this being the case the friction should be omitted, blood should be taken from the part, and some time should elapse before the friction is resumed. It is sometimes productive of very essential benefit, but not unless it be employed to a considerable extent, as for two or three hours daily, and during a long period of time." He also mentions having "sometimes tried the effect of pumping hot water on a stiff joint, as recommended by Le Dran, and now practised at some watering-places. The blow of a column of water, falling from a height of several feet, produces considerable friction, even so as to excoriate the surface, with which are combined the relaxing powers of heat and moisture. This practice is certainly productive of benefit; but the observations just made apply to this as well as the other modes of producing friction." (p. 40–42.)]

215. If there be already thickened synovial membrane, and, if the acute have passed into the chronic condition, leeches must be repeatedly applied, but in small numbers, waiting, however, each time till the erysipelas thereby excited has subsided. If the swelling be soft, light compression may be employed, mercurial or iodine ointment used; continued derivation by blisters and issues, and moxas or the actual cautery applied (1).

When suppuration occurs in the joint, with destruction of the cartilages and bones, care must be taken for the proper discharge of the pus (2); the limb must be kept in the most perfect rest; the powers supported by the use of tonic remedies, and a proper attention to diet; and poulticing must be continued. If exhaustion be feared, the removal of the limb is indicated.

[(1) When the inflammation has become actually chronic, especially if there be thicking, then irritating applications are especially beneficial. In the milder form soap liniment, either alone, or rendered more stimulating by the addition of *liquor ammoniæ*, or *tinctura lyttæ*, in proportion of a drachm to the ounce, the liniment of ammonia, with oil of turpentine, as recommended by Brodie, or mustard liniment, made by macerating an ounce of mustard flour in a pint of spirit of turpentine, are often sufficient. When more active excitement is necessary, friction with croton oil, about a dozen or twenty drops every evening till it brings out little blisters, which soon run into suppuration, is very serviceable, and a very cleanly application. Brodie recommends a liniment consisting of *ol. olivæ* ℥jss., *ad. acid. sulph.* ʒss.; but, if the patient's skin be delicate, or very tender, less acid must be used; it excites some degree of inflammation of the skin, and the cuticle browns, and is thrown off in thick broad scales. Some persons paint the whole joint over with tincture of iodine, which often acts like a blister. Mercurial ointment, with or without camphor, is frequently used, or ointment of iodide of lead; these are best applied upon lint without rubbing, as the former, if rubbed, often causes ptyalism in delicate persons especially, and the latter soon irritates the skin so much, that its discontinuance is compelled. The use of pressure, with straps of soap plaster, is often very comfortable and beneficial, and may be combined with stimulation of the skin, by using *emp. thur. comp.*, *emp. ammon. c. hydr.*, or *emp. picis Burg.* Tartarized antimonial liniment was a favourite remedy of Astley Cooper's; but it requires to be used with great caution, as, in persons with delicate skin, it often very speedily excites violent inflammation, with a very large crop of pustules, which become extremely painful, and often degenerate into deep and tiresome sores.

(2) The puncture of a joint when fluctuation is accompanied with other symptoms which lead to the presumption of pus being confined in its cavity is, though highly necessary if there be much constitutional excitement, and specially if the abscess point, not always unattended with inconvenience or even danger, and not certainly beneficial to the patient, of which the following is an instance:

Case.—J. P., aged twenty-five years, a baker, came under my care in the year 1843. Three months after having had typhus fever four years and a half since, his right knee became weak, and he began to limp; at this time there was not any swelling of the joint, but during the following six months the knee swelled, and he was under medical treatment; an abscess formed below the knee-cap, and burst subsequently by two wounds below and on the inside of the tubercle of the shin-bone. A discharge continued for four or five months, during which he followed his business, and walked about a good deal. The wounds at last healed, but soon after swelling occurred below and around the knee-cap, and thirteen months since it suppurated, and continued discharging on the apex of the knee-cap till the beginning of April in this year. During nearly the whole of this time he has walked, though not without pain, but has been unable to follow his business. The discharge having ceased, general swelling of the whole knee commenced, and he began to feel weakness on the sides of the joint. Being thus again crippled he came into the hospital

May 2, and I presume (for I did not make any note of his case at the time) I then considered his case as chronic inflammation of the synovial membrane, as he was treated by repeatedly blistering the joint, but the disease has not been at all checked. It is only however, within a fortnight from the present time (*Aug.* 19) that I have begun to think very seriously of his condition. During this time his sleep has been disturbed by shooting pain on the outside of the knee, the pain extending down the leg, always coming on as he falls asleep, and rousing him completely. Latterly he has lost flesh; his pulse is small and quick; but he does not sweat much, and his appetite is good.

The joint is now a good deal swollen and fluctuating, especially above the base of the knee-cap, and on the condyles of the thigh-bone, and less distinctly below the former bone. It is tender on pressure about the middle of the joint on the outside, and above the knee-cap on the inside. He has great pain on the slightest motion: pain on striking up the leg; and on pressing the articulating surfaces together, and twisting the leg upon the thigh causes severe pain; but no grating of the bones can be felt, though perhaps it might be, were not the movement of the limb so painful as to forbid persisting in attempts to ascertain it.

As I felt pretty confident that the joint contained pus, I determined, although it did not point, to evacuate it, and try if it were possible to bring about anchylosis by keeping the parts perfectly quiet, and establishing issues to promote a diversion of the irritation of the joint. And therefore in the afternoon of this day,

Aug. 19. Made a puncture with an abscess lancet on the outside of the base of the knee-cap, where the skin was thinnest. Blood flowed rather freely (about two ounces) at first, but on introducing a director about an ounce of synovial fluid escaped. As no pus appeared, and as the director did not give the sensation of touching any articular surface, I presumed I had only opened the bursa above the knee-cap, and thought it best to close the wound and obtain adhesion as soon as possible, by bringing the edges together with adhesive plaister; for although blood continued flowing from between the lips of the wound, I expected the slight pressure would stop it. The tension was diminished, and the patient was relieved from pain on the inside of the knee immediately on the discharge. Shortly after the wound had been brought together the knee began to swell again and feel distended, and in about a quarter of an hour or twenty minutes the oozing of blood, which had been rather free, was converted into a stream, which flowed freely, and was checked partially by pressure on the artery at the hip-joint, but still the bleeding continued for some time, and he lost twenty-six ounces of blood, when he became very faint. The swelling of the knee, which had been at first very hard gradually diminished and softened as the blood flowed. A tourniquet was applied high up, and the bleeding completely arrested. But he had become so faint and his pulse so weak and fluttering, that it was necessary to give him five ounces of wine and four ounces of brandy before he could be brought round.

Two hours after. I saw him again; he had then rallied, but was still very pale, and his pulse small, weak, and quick. The swelling of the knee, however, being soft, and no hæmorrhage having recurred, the tourniquet was removed, and an evaporating lotion applied to the knee.

I presumed that the bleeding depended entirely on the increased vascularity of the synovial membrane, and not from wound of either of the articular arteries, which, however, might have been the cause. The almost immediate recurrence of the swelling is accounted for by the closure of the wound preventing the external escape of the flowing blood, which was therefore retained in the synovial cavity. No further bleeding occurred; but as his health continued failing, it was determined to amputate the knee, which I did, and he recovered.

On examining the joint, the whole of the synovial membrane lining the capsular and extending over the other ligaments of the joint was found covered with a vascular, thick, soft, and granular substance. The cartilage on the edge of the patella was partially absorbed, as also that on the left articular cavity of the head of the tibia in a semi-circular form, and on both condyles of the thigh-bone it was partially removed, these corresponded to the granular substance on the synovial membrane; and a groove on the cartilage of the internal condyle answered to a remarkable slip of the granular substance, which crossed between and connected the capsular and crucial ligaments. There was not any pus on the joint; but the wound by which the lancet had entered, as it proved to have done, was distinct.—J. F. S.]

C.—OF INFLAMMATION OF THE CARTILAGES.

216. The joint-cartilages may be the primary seat of inflammation (*Inflammatio Cartilaginum*, Lat.; *Entzündung der Knorpel*, Germ.; *Inflammation des Cartilages*, Fr.) and ulceration, which may thence be propagated over the other structures of the joint.

[Before considering the effects of inflammation, and its results on cartilage, it will be well to take a view of the opinions which have been, and are, held as regards its vascularity or non-vascularity, not only on account of the difference of opinion there is upon these points whilst cartilage is in a healthy state, and during its growth, but, also, because upon one or other of these views are founded the different opinions held in reference to their activity or passiveness in the production of the diseases with which they are affected.

Structure of Cartilage.—WILLIAM HUNTER (*a*) examined articular cartilages previously prepared by boiling, or long-continued maceration, and thus describes them :—" When an articular cartilage is well prepared it feels soft, yields to the touch, but restores itself to its former equality of surface when the pressure is taken off. This surface, when viewed through a glass, appears like a piece of velvet. If we endeavour to peel the cartilage off in lamellæ, we find it impracticable, but if we use a certain degree of force, it separates from the bone in small parcels, and we never find the edge of the remaining part oblique, but always perpendicular to the subjacent surface of the bone. If we view this edge through a glass, it appears like the edge of velvet, a mass of short and nearly parallel fibres rising from the bone, and terminating at the external surface of the cartilage; and the bone itself is planned out into small circular dimples where the little bundles of the cartilaginous fibres were fixed. Thus we may compare the texture of cartilage to the pile of velvet, its fibres rising up from the bone, as the silky threads of that rise from the woven cloth or basis. In both substances the short threads sink and bend upon being compressed, but by the power of elasticity recover their perpendicular bearing as soon as they are no longer subjected to a compressing force. * * * Now these perpendicular fibres make the greatest part of the cartilaginous substance; but, without doubt, there are, likewise, transverse fibrils which connect them, and make the whole a solid body, though these last are not easily seen, because, being very tender, they are destroyed in preparing the cartilage. * * * The blood-vessels are so small that they do not admit the red globules of the blood; so that they remained in a great measure unknown till the art of filling the vascular system with a liquid wax brought them to light. Nor even by this method are we able, in adult subjects, to demonstrate the vessels of the true cartilaginous substance; the fat-glands and ligaments shall be red with injected vessels, while not one coloured speck appears upon the cartilage itself. In very young subjects, after a subtle injection, they are very obvious; and I have found their course to be as follows: all round the neck of the bone there are a great number of arteries and veins which ramify into smaller branches, and communicate with one another by frequent anastomoses like those of the mesentery. This might be called the *circulus articuli vasculosus*, the vascular border of the joint. The small branches divide into still smaller ones upon the adjoining surface in their progress towards the centre of the cartilage. We are very seldom able to trace them into its substance, because they terminate abruptly at the edge of the cartilage, like the vessels on the *albuginea oculi*, when they come to the *cornea*. The larger vessels which compose the vascular circle, plunge in by a great number of small holes, and disperse themselves into branches between the cartilage and bone. From these again there arises a crop of small short twigs, that shoot towards the outer surface; and whether they serve for nourishing only, or if they pour out a dewy fluid, I shall not pretend to determine. However that be, I cannot help observing that the distribution of the blood-vessels to the articulating cartilages is very peculiar, and seems calculated for obviating great inconveniences. Had they run on the outer surface, the pressure and motion of the two cartilages must infallibly have occasioned frequent obstructions, inflammations, &c., which would soon have rendered our motions painful, and at last entirely deprived us of them. But by creeping round the cartilaginous brim, where there is little friction, or under the cartilage, where there is none, they are perfectly well defended from such accidents. It were to be wished we could trace the nerves of cartilages: but, in relation to these organs, here, as in many other parts of the body, we are under a necessity, from the imperfection of our senses, of being satisfied with mere conjecture; and though, from the great insensibility of a cartilage, some have doubt of its being furnished with nerves; yet, as it is generally allowed, that these are a *sine quâ non* in the growth and nourishment of animals, we have no sufficient reason to deny their existence in this particular part. With regard to the manner of their distribution, we may presume, from analogy, that they follow the same course with the blood-vessels." (p. 515–19.)

MIESCHER (*b*) says there is not the least difference between permanent cartilage and that which is to be converted into bone. (p. 15.) His observations in regard to articular cartilages do not, however, agree with WILLIAM HUNTER's as regards their actual fibrous structure. He observes:—" When articular cartilages have been thrown for some time into acid, they can easily be separated from the other cartilage which was

---

(*a*) Above cited.

(*b*) De Inflammatione Ossium eorumque Anatome generali. Berolini, 1836. 4to.

bony. They are more easily split transversely than in any other direction, their broken surface presents a fibrous appearance, but when placed under the microscope forthwith lose it, and exhibit none other than a regular pellucid substance with ovate corpuscles. These are ranged in the manner of clusters; their longitudinal diameter is situated transversely, as is very distinctly perceived in the thick cartilage covering the joint surface of the knee-cap. On the corpuscles being thus arranged depends the fibrous appearance." (p. 25.)

Todd and Bowman (*a*), however, consider there is a difference between temporary and articular cartilage. In the latter "the cells are oval or roundish, often disposed in small sets of two, three, or four, irregularly disseminated through a nearly homogeneous matrix which is more abundant than in the former." This, however, is in reality all the difference which even they point out, as although they say "in the inner part of the cartilages of incrustation (a term applied to articular cartilages by some anatomists) we usually find the cells assuming more or less of a linear direction and pointing towards the surface, which arrangement is probably connected with a corresponding peculiarity of texture of the intercellular substance, but which it is more difficult to distinguish; for these specimens have a disposition to fracture in a regular manner along planes vertical to the surface, and the broken surface is striated in the same direction." Yet had they previously stated, in reference to temporary cartilage, "When ossification begins, the cells which hitherto were scattered without definite arrangement become disposed in clusters or rows, (Miescher's exact expression *corpuscula racemorum in modum consita*,) the ends of which are directed towards the ossifying part." (p. 90.)

The fibrous structure of articular cartilage as described by William Hunter is explained in the following way by Henle (*b*):—"I have sometimes observed," says he, "the contour of the cavities projecting from one longitudinal row of cavities (in the cartilage) to the next, and it appeared as if a part of the cavity together with the enclosed cells were separated by a cleft. It is, however, possible that these are the hollow parts of one system of long canals which twisted, or perhaps also in rare cases divided angularly, penetrate the cartilage from its lower towards its upper surface, and remain in the cleft partially in the one and partly in the other segment. By this formation is satisfactorily explained why the articular cartilage presents a fibrous fractured surface, and seemed to the old observers to consist of fibres which ran perpendicularly through its thickness. Next the free surface they are more lamellar and can be separated into delicate plates (Meckauer). The flattened cells of this layer have the closest resemblance with the epithelial cells of the synovial membrane and often subside imperceptibly into it; but usually a layer of connecting tissue forms the boundary between them." (p. 796.)

"Most cartilages," says Henle, "are devoid of vessels. The joint-cartilages at their adhering surface are in contact with the very vascular bones, at their free surface they are overspread with synovial membrane; in the connecting tissue of which, however, in the newly born child, and sometimes even in the adult, vessels pass from the edge, and are rendered apparent by injection. Perhaps they originally cover the entire surface and subsequently are obliterated towards the edge from which they are reflected out of the synovial membrane upon the capsular ligament. But in the adult no branches either from the bone or from the synovial membrane penetrate into the cartilage." (pp. 802, 3.)

"The cartilaginous covering of joints is not at first separate from that part of the bone cartilage which will be ossified. During the period of ossification there is a considerable layer of vessels between the cartilage and the already perfectly ossified parts, and it is easy to separate the two parts" (as already stated by Hunter.) "Both have irregular surfaces, elevations, and depressions, by which they hold together. In proportion as ossification extends towards the epiphysis, the vascular layer shrinks and the adhesion becomes more intimate. In newly-born children, however, pretty wide but only slightly branching canals with blood-vessels from without, and from the surface, covered with synovial membrane, penetrate the cartilage deep enough to reach the epiphysal cartilage. * * * When the formation of cartilage is completed, the vessels retract from it, and in the adult its nutrition seems derived only from the vessels of the adjacent bone and perichondrium, perhaps in the joint cartilages also mediately from the synovia which comes from the vessels of the synovial membrane, and the so-called Haverschian glands. The taking up of the plasma thus follows by saturation and thereto seems the special use of the cavities of cartilage. * * * Macerated cartilage is often distinctly

---

(*a*) Physiological Anatomy and Physiology of Man, chap. iv. London, 1843. 8vo.

(*b*) Allgemeine Anatomie. Lehre von den Mischungs und Formbestandtheilen des menschlichen Körpers. Leipzig, 1841. 8vo.

reddened by imbibition of the red colour of the blood, and the reddening is greater, the more the cells proportionally exceed the basement; most distinctly therefore in fœtal cartilage. If the blood in the living body carry unnatural colouring substances, as for instance the bile pigment, it penetrates the cartilage, which, therefore, in jaundice, becomes yellow, as noticed by BICHAT." (pp. 808, 9.)

TOYNBEE (*a*) observes, in reference to articular cartilage:—"Although they are properly considered as non-vascular tissues, they appear to be pervaded by blood-vessels at an early period of their development, or, perhaps, it would be more correct to say, that as growth proceeds, the cartilage increases, so as to occupy the space that had previously been permeated by vessels. I have been able," he continues, "to demonstrate that vessels are never found within these cartilages when fully developed; but at that period vessels form convolutions in their immediate vicinity. These vessels are separated from articular cartilage, at adult age, by a layer of bone; and in fibro-cartilage, at the same period, they uniformly terminate within the boundary of its fibrous tissue. Over a certain portion of the free surface of both these tissues blood-vessels extend, but they do not penetrate into their substance. The investigations which are about to be detailed lead, I think, to the certain conclusion, that articular cartilage in the adult state is principally nourished by fluid derived from the vessels of the cancelli of the bone to which it is attached, which exudes through the coats of those vessels, and makes its way into the substance of the cartilage through the intermediate lamella of bone. The cartilage of fibro-cartilage is nourished, in like manner, by *liquor sanguinis*, derived from vessels situated in the contiguous fibrous portion. The vessels ramifying in a certain extent of the free synovial surface of both these species of cartilage, contribute, doubtless, to their nutrition, but not to near the same extent as do the vessels of the opposite side. With respect to the actual process of nutrition, I shall only observe here, that the cells of these structures must be regarded as having the function which has been ascribed to those of all non-vascular tissues, viz., that of promoting the circulation of and modifying the nutrient liquor. In connexion with this process, however, it will be seen that articular cartilage presents, in its adult state, very minute canals, which may be regarded as existing for the reception of the nutrient fluid, and for its circulation through the mass of cartilage; their presence is especially required in this particular form of cartilaginous structure, from the great degree of density which it possesses. * * * The portion of bone upon which articular cartilage rests is, in some instances, formed by the ossification of a distinct cartilaginous epiphysis. In non-epiphysal bones, the extremity of the shaft of the bone performs the same functions with regard to the articular cartilage situated upon it as do the epiphyses in those bones which are provided with them. There is this difference in articular cartilage, with regard to its nutrition during and after its development, that in the former state there is no positive separation of it from the cartilage which is subsequently converted into bone, and in which its nourishing vessels are contained; whilst, in the latter state, these vessels are separated from it by an osseous lamella. The free surface of articular cartilage during, as well as after, its development, is covered by synovial membrane, to which it is attached by cellular membrane." (pp. 162, 3.)

TOYNBEE concludes, from examinations he has made, "that during the most early periods, the cartilage of the epiphysal extremities of bones does not contain any blood-vessels, and that, notwithstanding their absence, the cells of this cartilage are developed, and its growth carried on; and that, at the same time, the cells of the epiphysal and the articular cartilage are formed and developed without the presence of vessels;" and "that, at the more early period of fœtal development, the synovial surface of cartilage does not contain blood-vessels." (pp. 164, 5.)

According to the same observer, in the second stage of development the epiphysal cartilage "presents, except at its articular surface, numerous depressions of various depths. The deepest may be regarded as canals, some of which are single, others bifid; they terminate in blind sacs. The direction of some of these canals is towards the centre of the epiphysis, of others towards its point of attachment to the osseous shaft, and of others towards the articular cartilage. Some of these canals are of a large size, and are frequently considerably dilated at their blind extremities. They do not penetrate into the substance of the articular cartilage; they are for the reception of branches of sanguiferous vessels. When the epiphysis is minutely injected, the depressions upon its surface will be found to contain congeries of convoluted vessels, which are more drawn out the deeper the depression, until at length, in the interior of the canals and their divisions, single and nearly straight vessels are found. These epiphysal vessels have a very peculiar disposition. They consist of an artery having a course more or less

---

(*a*) Already cited.

straight, which terminates in a dilatation, or in convoluted branches, from which the vein arises. From the fact of the presence of these vessels, which converge towards, and form convolutions internal to the articular cartilage, it may be inferred that they supply the cells of the latter with a nutrient fluid. As the articular cartilage increases in thickness, and the ossific nucleus which is developed in the epiphysal cartilage becomes larger, these vessels gradually recede from between them, and leave a considerable mass of non-vascular cartilage between the osseous nucleus and the synovial membrane; all of this appears to be articular cartilage, which is now nourished by the vessels in the interior of the nucleus. The supply of blood-vessels in the cancelli of the osseous nucleus is remarkably abundant; they are large, and are separated from the surrounding cartilage by an extremely delicate lamina of bone, which is principally made up of osseous cells. I am induced to believe that at this stage of development, as in adult age, the fluid passes from the bone into the cartilage and nourishes it. * * * The articular cartilage, at this early period of life, is thicker than in the adult state. Although devoid of canals for the reception of blood-vessels, it presents numerous minute canals, which pervade that portion of it contiguous to the osseous nucleus, and they course from the latter towards the synovial membrane, which, however, they do not reach. * * * They are minute, and extremely numerous; they divide, sub-divide, and communicate with each other, and form dilatations. The parietes of these canals present distinct rounded cells, which in some places are arranged in rows and groups. The substance between these tubes is transparent, and contains no corpuscles. The articular cartilage above described is gradually being converted into bone during the whole of life." (p. 165-7.)

The nutrient vessels of articular cartilage during its development, which are situated betwixt it and its synovial membrane, "are contained and ramify in a considerable layer of cellular tissue," by which that membrane is attached to the articular cartilage, and from which Toynbee detached nearly the whole. His statement, however, that "these vessels have been alluded to by Dr. William Hunter under the name of 'circulus articuli vasculosus,'" is quite incorrect, as reference to the passage already quoted will prove; in which Hunter says, they "plunge in by a great number of small holes, and disperse themselves into branches *between* the cartilage and the bone;" and not "*on* the entire surface of the articular cartilage," as described by Toynbee. "It is difficult," says this latter writer, "to state generally at what period of fœtal existence these vessels, which have been spoken of in the first stage as forming convolutions around the joints, are prolonged upon its (the articular cartilage's) surface." But, after having studied with care these stages, he states, that "at between the *third* and *fourth* month of fœtal life these vessels are simply a mass of delicate convolutions, situated between the synovial membrane; at the *fifth* month, these convolutions are somewhat unravelled, so as to extend over the surface of the cartilage to the distance of about half a line; and at between the *seventh* and *eighth* months, they are drawn out and prolonged to the distance of a line and a half. At this stage, these vessels consist of arteries of considerable size, which radiate in a straight course from the attachment of the *ligamentum teres*. They give off but few branches, and, previous to terminating, divide and sub-divide, but do not much diminish in size. They terminate by turning and forming loops with the small veins. Subsequent to the *eighth* month these vessels begin to recede in their course; and at *birth*, and the periods subsequent to it, they are again found to be gathered immediately around the point of attachment of the *ligamentum teres*. After these vessels have receded, the position they occupied at the more early periods may be for some time detected by the white aspect of the cellular tissue between the cartilage and the synovial membrane." In the knee-joint there is a little difference: "The arteries which have run straight towards the centre of circulation, give off small branches, forming a delicate net-work communicating with the small veins, and terminate either by turning in their course, and forming broad loops with the venous radicles, or empty themselves into a single vessel from which the veins arise." (p. 168.)

The canals in adult cartilage, already mentioned, Toynbee describes as "irregular in their distribution; some are merely dilated cavities; frequently several of these cavities are elongated and arranged serially, running from the attached towards the free surfaces of the cartilage. At the free or synovial surface these canals do not exist; the cells of the texture at this part being elongated and flattened, and having their long diameters parallel to the free surface. These canals contain a transparent fluid, which is seen to ooze from them after a section. It is most probable that the uninjected vessels mentioned by Meckel, Bichat, and others, were these canals and sinuses." (pp. 169-70.) The observations just alluded to are the following:—Meckel (a) says,

---

(a) Handbuch der Menschlichen Anatomie, vol. i. Halæ et Berol., 1815-20.

"Cartilages do not receive vessels carrying red blood, although in cutting them distinct vessels are frequently observed in their substance." **Bichat** (*a*) observes that in cartilage "no blood-vessels are distinguishable. The exhalant system carries only white juices; but as this system is continued to the arteries of the neighbouring parts, so that the organic sensibility is there elevated by weak irritants, and so brought into relation with the red globules of the blood, that they pass readily, whence arises the redness which cartilage assumes, as seen in inflammation, wounds, &c. It is exactly the same as occurs in inflamed conjunctiva, &c. When the irritation ceases, the sensibility resumes its natural type, and the red globules at the same time become alien to the cartilage, which recovers its whiteness. We know not the nature of the white fluids ordinarily circulating in the vascular system of cartilage. They are very susceptible of becoming the vehicle of the bile, or, at least, of its colouring substance, when diffused throughout the animal economy in jaundice." (p. 129-30.) **Müller** (*b*) states, that "in tendons, ligaments, and cartilage, there are blood-vessels, but few in number." (p. 362.)

In **Brodie**'s opinion the cartilages are vascular. He says:—"Up to the period of growth being concluded, we must suppose the articular cartilages to be vascular, otherwise we cannot account for the changes of bulk and figure which mark their progress towards complete development. In the child, canals or sinuses may be seen ramifying through their substance, containing blood, and manifestly intended to answer the purposes, though not constructed with the distinct tunics of ordinary blood-vessels. In the adult person these canals for the distribution of blood are not perceptible. This proves that they are very minute, but not that they are altogether wanting." (p. 111.) He also supports his opinion by the analogy of "the transparent cornea of the eye, in which no vascular structure can be detected under ordinary circumstances, but the existence of vessels in it is proved by the changes which it undergoes in disease; and when it is inflamed such vessels become distinctly visible, injected with red blood. So we meet with occasional though rare instances of vessels containing red blood extending from a diseased bone into the cartilage covering it." Also by the exposure of the joint cartilages to friction without being affected by it, which "cannot be explained unless we admit the cartilages to possess a power of reparation; and this must be supposed to depend, as in other textures, on the action of blood-vessels modified by that of the absorbents." And lastly, he brings forward the occasional conversion of an articular cartilage "into a number of ligamentous fibres, each of which is connected by one extremity to the bone, whilst the other is loose towards the cavity of the joint. Here is a morbid alteration of structure, the occurrence of which seems to indicate that there must be such a vascular apparatus entering into the formation of cartilage as enables new materials to be deposited and old materials to be absorbed, and without which morbid alterations of structure do not take place in other parts of the body." (p. 111-13.)

Toynbee, however, asserts, that "into the substance of healthy cartilage he has never been able to trace blood-vessels, and his researches induce him to believe that they do not possess any. (p. 170.) Of the same opinion, also, is **Beclard** (*c*), who says:—"These cartilages have no vessels; delicate injections and microscopic examinations exhibit the capillary vessels terminating at the circumference and adhering surface without ever penetrating their substance." (p. 466.) And **Cruvelhier** (*d*) still more decidedly affirms, that "the diarthrodial cartilages do not present any trace of organization." (p. 162.)

The importance of the subject will, I trust, be sufficient apology in regard to this long anatomical digression, in which it will be observed that **William Hunter** appears to have held generally very correct views on the structure of cartilage, excepting as to its fibrous character. The reader will also be struck with the near resemblance of the opinions held by **Toynbee** and **Henle**. I have, indeed, mentioned those of the latter author first, as in the course of the narrative it was convenient so to do. But the statements of both were published in the same year, and it is scarcely possible that either could have had knowledge of the views of the other.—J. F. S.]

At first, the patient feels only little and passing pain, which is increased by the motions of the joint, but ceases when it is at rest. It gradually becomes continuous, and spreads from the joint over the bones. After several weeks or months, the swelling of the joint is affected with a slight external inflammation. This swelling is neither great nor fluctuating, and has pretty much the form of the joint. After a shorter or longer time,

(*d*) Observations sur les Cartilages Diarthrodiaux; in Archives Générales de Médecine, vol. iv.

suppuration in the joint occurs: it breaks, and hectic fever destroys the patient. Although the course of this disease is nearly always insidious in its beginning, peculiar conditions may increase the symptoms, and the disease assume an acute form.

Mayo (*a*) speaks of "three distinct forms of ulceration" of joint-cartilages, which, although they may be occasionally combined, are oftener met with separately. (p. 49.) *First.* Rapid absorption of cartilage beginning on its synovial aspect; the new surface, if cartilaginous, being smooth and unaltered in structure; if of bone, healthy; the absorption of cartilage being attended with inflammation of the capsular synovial membrane. (p. 50.) This form is "of rare occurrence. The absorption of cartilage takes place rapidly. It is attended with severe pain, with inflammation of the capsular synovial ligament, and generally with suppuration in the cellular tissue adjacent to the joint. The only favourable termination of the disease, that I have witnessed, is anchylosis. *Second.* Chronic ulceration of cartilage beginning on its synovial aspect, producing an irregularly excavated surface with fibrous or brush-like projections of the cartilage and synovial membrane, attended with inflammation of the capsular synovial membrane, and sometimes of the same membrane where it is reflected over the cartilage, the bone and the surface of cartilage towards it being healthy. (p. 53.) *Third.* Absorption of cartilage beginning on the surface towards the bone, attended with inflammation of the adjacent surface of the bone, with inflammation of the synovial membrane, and sometimes with sensible vascularity of the cartilage itself." (p. 59.)

[As to the inflammation of cartilage, if such there be, **Wilson** (*b*) observes, "the active powers of life are possessed by articular cartilages in a very limited degree, so much so, that the ocular demonstration is wanting of their being *capable* of inflammation. This affection is in other parts marked by a state of vessels easily distinguished by the eye and by the touch; but, as vessels are not to be seen or felt in these cartilages, we have not sufficiently decisive proofs of inflammation ever taking place in them. I have never seen in articular cartilages, which were completely formed, any vessels either filled with its own blood or having its cavity distended by injection." (pp. 327, 28.)

John Hunter (*c*) takes no notice of this point at all; but, after speaking of the union of fractured cartilage by bone, proceeds:—"Sometimes the inflammation goes on to suppuration; but they (the cartilages) seem to have insufficient power to admit of ulceration, yet they may be absorbed by the absorbents of other parts, as in white swellings, when suppurated, the cartilaginous ends are removed by the absorbents on the surface of the ends of the bone that the cartilage covers. It may be ulcerated in this manner in other joints also: in the knee we find all the different stages of absorption of cartilage; granulations will shoot from under the cartilage, and sometimes, when there is not much matter in the joint, these granulations will inosculate and form a bony union. (p. 535.)

Wilson says that "the synovial membrane which lines the capsular ligament, and is reflected from it over part of the bone to the edge of the articular cartilage, will indeed sometimes pass a little way on the surface; it there becomes inseparably connected with the cartilage, and its appearance is then lost." But he continues:—"In a diseased state of joint, I certainly have seen the surfaces of the articular cartilages covered by a membrane, but this membrane I have no reason to believe to have been originally more than a coating of coagulable lymph; it is of different degrees of thickness, and at first easily peels from the surface it covers, but it soon becomes organized and very vascular. In a preparation, belonging to the Windmill-street museum, vessels seem to pass from this new formed membrane into little inequalities on the surface of the cartilage, and it is far from improbable but that absorbent vessels may be among these, and which are employed, along with the absorbents from the bone, in removing the articular cartilage. * * * I do not mean to deny the possibility of the removal being attempted partially by vessels belonging to their own substance, so as to produce some of the appearances called ulceration of cartilages; but we are deficient in proofs of this, and, from what I have observed of the state and appearance of diseased joints, I am induced to abide by the opinion entertained by **John Hunter**, that the removal of articular cartilages is generally effected by the vessels of the neighbouring more vascular parts, viz., of the bones and synovial ligaments, and occasionally by the vessels of coagulated and organized lymph." (pp. 328, 29.)

(*c*) Lectures; **Palmer**'s Edition.

Brodie, however, holds there is "sufficient to prove that the articular cartilages may be absorbed or ulcerated from the action of their own vessels, and that the ulceration may begin, and frequently does begin, on that surface which is towards the articular cavity. At the same time it is to be observed that in many instances the ulceration begins in another situation, and I have frequently seen the cartilage abraded where it had been in contact with the bone, while on the surface, towards the cavity of the joint, it remained smooth and perfect. Under these circumstances the space formed by the absorption of the cartilage becomes filled up by a vascular substance resembling granulations, and uniting the bone and cartilage to each other. In whatever way the ulceration of the articular cartilages is produced there is this remarkable difference between it and the ulceration of soft parts: suppuration seldom takes place while the ulcer of the cartilage is small, and often the disease proceeds so far as to cause caries of the bones to a great extent without matter being formed in the joint. This circumstance is deserving of notice. It has long been established, that suppuration may take place without ulceration, and it appears that, in this instance, ulceration occurs without the formation of pus." (pp. 116, 17.)

Lawrence (*a*) also says, that "ulceration of cartilage" not only takes place from other causes, but "as an original affection of the joints. Without any disease of the synovial membrane, without the occurrence of any accident or injury, it may commence as a primary or original affection of the joint itself. The ulceration is attended with two circumstances which are very different from those we observe in ulceration of other structures. There is no formation of pus, nor do we ever find granulations produced from diseased cartilages—no attempt at reproduction of the cartilaginous structure. Although ulceration of the cartilages may be in the first instance limited to the cartilaginous structure itself, yet it soon involves other parts of the joint. It extends in the first place to the bony articular extremities, which become ulcerated, and are, in common language, rendered *carious:* the synovial membrane and external soft parts about the joint become inflamed: small abscesses form and break externally; a succession of these takes place in various parts of the joint, and a number of fistulous openings are established about the joint, giving place to matter, and, in many cases, to carious portions of bone. The ulcerative process often extends to the ligaments that connect the articulations; the consequence of which is, that the bones are no longer retained in their relative positions, but are thrown into certain unnatural directions by the action of the strong muscles of the limb." (p. 483.)

According to Key's views, the ulceration of cartilages, commonly so called, depends on four conditions, in three of which "the cartilage," he says (*b*), "is not absorbed *per se*, but through the agency of a structure, probably evolved for the special purpose of completing that process," and the fourth is "the result of disorganization of texture." The first two forms, viz., "the loss of articular cartilage that attends upon the chronic inflammation of the synovial membrane, and the more active destruction of the articular cartilage that attends acute inflammation of the joint," appear to me simply modifications of the same process by the degree of the inflammatory action, and, therefore, to be considered as one form, either in its chronic or acute stage, as may be, the result of which is the production of a vascular and absorbing membrane from the synovial membrane. The next is "the absorption of cartilage that accompanies strumous disease of the cancellated structure of bone," or that condition mentioned by Brodie, in which "the cancellous structure of the bones is the part primarily affected; in consequence of which ulceration takes place in the cartilages covering their articulating surfaces." (p. 226.) The consideration of this form must be deferred to Inflammation of the Joint-ends of Bones. (*par.* 221–24.) The last condition, much less frequent, is that in which Key says, "that structure (cartilage) appears to undergo a change in its organization, independent of foreign agency. * * * An action altogether different from absorption, and analagous to the softening of the intervertebral substance." To which he applies the term "disintegration, in contradistinction to absorption, the one being a loss of substance from an absorbing action, the other being the result of a disorganization of texture. It is the primary ulceration of cartilage described by authors." (pp. 134, 35.)

Of the absorption of cartilage by a new membrane produced by inflammation of the synovial membrane,

Key (*c*) thus speaks:—"In a manner analogous, in many respects, to the process of removing dead bone, does nature achieve the task of absorbing the cartilaginous structure covering the articular extremities of bones. These structures possess but

(*b*) Further Remarks on the Ulcerative Process; in Med.-Chir. Trans., vol. xix.

(*c*) On the Ulcerative Process in Joints; in Med.-Chir. Trans., vol. xviii.

a low degree of organization; in their healthy condition they present very few of the characters of animal vitality: they exhibit scarcely any trace of red blood vessels, and, for obvious reasons, their supply of nervous influence is not more than sufficient to connect them with the surrounding structures, as part of a whole. Under disease they exhibit that want of action which might be anticipated from the limited extent of their organization. In acute inflammation of a joint, while the synovial membrane and ligaments are much altered, the cartilage appears unchanged in colour or in texture, and apparently uninfluenced by the increased action going on in the surrounding parts. The cartilage becomes, under disease, softer somewhat in texture; but this change may be as well attributed to the absence of pressure as to the effect of inflammatory action; for healthy joints when kept long at rest are found to undergo a similar change, on their cartilaginous surface, from the want of that pressure to which they have been accustomed, and which may be necessary to the preservation of their due consistence. There are, however, some forms of inflammation under which the cartilage, very early in the disease, undergoes a change of structure: these instances are much less frequent, and may be looked on as exceptions to the ordinary rule." (pp. 216, 17.)

"The progress of ulceration in cartilage covering the ends of bone," continues KEY, "is not uniform in its course. The means by which it is effected vary according to the cause that gives rise to it. It is sometimes the result of acute synovial inflammation, or of a chronic affection of that membrane: it is occasionally found as a primary affection, independent of the other textures of the joint. * * * I am inclined to believe that inflammation of this membrane is the most frequent cause of ulceration of the cartilage. This opinion I have been led to adopt from the examination of a considerable number of diseased joints, in which ulceration of cartilage has been found to exist in different degrees of progress from its most advanced stage, in which the bone has been entirely denuded, to the very incipient abrasion of its surface or margin. The history of some of these cases, together with the morbid appearances, has also satisfactorily proved the existence of a long-continued synovial affection, before any alteration of the cartilaginous surface could have taken place, as the cartilage in some has been quite sound, with the exception of a slight loss of substance at the edge of the bone, where the synovial membrane is reflected from it: while the symptoms of diseased joint have existed for many months, with pain over a large part of the synovial surface, and general swelling of the joint. * * * The inflammation of the synovial membrane that leads to ulceration of cartilage in the ordinary strumous affection of joints in the adult, is not, as far as my observation goes, of the most acute kind. * * * The less acute forms of the disease, assuming various shades of activity between the chronic and the acute forms, rarely occur for any great length of time without the cartilage participating in the mischief. This may in some measure depend on the peculiarity of those constitutions in which sub-acute inflammation seems to have a spontaneous origin. The knee-joint is most frequently observed to suffer disorganization from this form of inflammation. * * * When the more acute symptoms are subdued (by treatment) the membrane sometimes fails to regain its normal condition, passing into a chronic form of action so slight as to attract but little attention, and often regarded as stiffness that will yield to exercise and passive motion. This slight degree of inflammation that remains often lays the foundation of future mischief, especially if the condition of the patient's health is not adverted to after the acute stage of the inflammation has subsided. The nature of the remedies employed always leaves the patient in a state of weakness and irritability, under which the low degree of action that remains in the joint will be disposed to assume the ulcerative form. * * * This state of joint as the disease advances is usually attended with more pain, than when the disease assumes from the commencement the chronic form; the intervals of ease become short and few; and the action goes on with but little interruption to the formation of abscess. In the chronic form of synovial inflammation that occurs in indolent habits of a strumous tendency, especially in persons below the age of puberty, years often elapse before the ulcerative process is completed. The symptoms are proportionally mild in their course. The joint is not much swelled, the general and uniform fulness of the joint, so characteristic, as BRODIE has observed of the most acute forms of inflammation of the synovial membrane, is absent; the joint appears as if the bones themselves were enlarged, an appearance as much produced by the shrinking of the limb above and below the joint as by the swelling of the joint itself. The swelling of the soft parts about the joint depends on the degree of inflammation present in the synovial membrane, and the consequent effusion in the soft parts. In the most chronic forms the bones can almost be felt through their ligamentous investments; in the less chronic forms, when the disease runs its course in a shorter period, there is effusion of albumen in the soft structures surrounding the joint, which increases its volume, preventing the bones being distinctly felt, and in some measure altering the form of the joint. (pp. 218-22.)

"The patella and the extremity of the femur are the parts on which the ulcerative process can be best traced, on account of the disease being in these less advanced. In the former bone, the first part that commonly gives way to ulceration is the margin of the cartilage, where the synovial membrane is reflected from it. At this point sulci of different depths are formed, which cannot be always distinguished until the thickened edge of the synovial membrane is raised. The ulcerated surface sometimes exhibits parallel vascular lines, verging towards the centre, and having their origin from the synovial membrane. The synovial membrane at this part, if the vessels are well filled with fine injection, appears highly vascular and fringed, or villous, like a mucous membrane. This increased vascularity is particularly noticeable at the edge of the membrane and in those portions of the fringed margin that correspond to the ulcerated surface of the cartilage; the other parts of the synovial membrane have their vascularity but slightly increased. This highly vascular fringe of membrane is a newly organised, and will be found in some parts to be a superadded, structure, for the purpose of producing ulceration of the contiguous cartilage. It may, when recently formed, be raised in some parts from the synovial membrane, but is found to adhere very slightly to that part of the cartilage where ulceration is going on; this adhesion is not perceived unless the joint is opened with great care. * * * The process, therefore, by which the ulceration of cartilage is in this case effected, is analogous to that by which the sequestrum of the cylindrical bones under necrosis takes place. Indisposed to ulceration, from the low degree of its organization, it is acted upon by the newly organised synovial surface, which is rendered highly vascular, and by means of its villous processes forms a groove in the edge of the cartilage, thus commencing the work of destruction. The cartilage at the edge is sometimes entirely destroyed, so as to lay bare the bone, in which case vascular granulations also arise from the surface of the exposed bone, and assist the membrane in the work of absorption. This, however, is more usually observed in the most acute form of inflammation. In the more chronic form, the vascular fringe of synovial membrane contracts adhesion to the surface of the cartilage in which ulceration is going on, and gives rise to the formation of a new membrane, which spreads gradually over the surface of the cartilage. A diseased joint is hardly ever examined without exhibiting one or more of the bones partly covered with this pulpy membrane. When injected, its vascularity is found to vary according to the activity of the inflammation in the joint; when first formed it exhibits considerable vascularity during the ulcerative process: when the cartilage has been wholly absorbed, and the ulcerative process has been checked by the inflammation being arrested, this membrane then serves another purpose; it becomes the medium of union between opposed surfaces of bone, or the means of anchylosis. Long after all inflammation has subsided, one of the condyles of the femur is often found adhering to the tibia by means of this membrane, which appears white and ligamentous; a layer of cartilage often remaining between the membrane and the bones, as if the process of ulceration were arrested." (p. 223-226.)

Goodsir (*a*) holds with Key in the deposit from the synovial membrane being the cause of ulceration in cartilage; for, as "in the thin articular cartilages of the adult human subject, few or no vessels can be detected, it is evident that in the process of ulceration in cartilage, it cannot be the usual blood-vessels of the part which are the active agents, still less likely is it that lymphatics, the existence of which has never been asserted in this texture, are the absorbing instruments." He then proceeds:—"If a thin section, at right angles, be made through the articular cartilages of a joint, at any part where it is covered by gelatinous membrane in scrofulous disease, or by false membrane in simple inflammatory condition of the joint, and if this section be examined, it will be found to present the following appearances. On one edge of the section is the cartilage unaltered, with its corpuscles natural in position and size. On the opposite edge, is the gelatinous, or false membrane, both consisting essentially of nucleated particles, intermixed, especially in the latter, with fibres and blood-vessels; and, in the former, with tubercular granular matter. In the immediate vicinity, and on both sides of the irregular edges of the section of cartilage, where it is connected on the membrane, certain remarkable appearances are seen. These consist, on the side of the cartilage, of a change in the shape and size of the cartilage corpuscles. Instead of being of their usual form, they are larger, rounded, or uniform; and, instead of two or three nucleated cells in their interior, contain a mass of them. At the very edge of the ulcerated cartilage, the

---

(*a*) **The Process of Ulceration in Articular Cartilages; in his Anatomical and Pathological Observations. Edinburgh, 1845. 8vo.**

cellular contents of the enlarged cartilage corpuscles communicate with the diseased membrane by openings more or less extended Some of the ovoidal masses in the enlarged corpuscles may be seen half released from their cavities by the removal of the cartilage; and others of them may be observed on the substance of the false membrane, close to the cartilage, where they have been left by the entire removal of the cartilage which originally surrounded them. If a portion of the false membrane be gradually torn off the cartilage, the latter will appear rough and honeycombed. Into each depression on its surface a nipple-like projection of the false membrane penetrates. The cavities of the enlarged corpuscles of the cartilage open on the ulcerated surface by orifices of a size proportional to the extent of absorption of the walls of the corpuscle, and of the free surface of the cartilage. The texture of the cartilage does not exhibit, during the progress of the ulceration, any trace of vascularity. The false membrane is vascular, and loops of capillary vessels dip into the substance of the nipple-like projections which fill the depressions on the ulcerated surface of the cartilage; but, with the exception of the enlargement of the corpuscles, and the peculiar development of their contents, no change has occurred in it. A layer of nucleated particles always exists between the loops of capillaries and the ulcerated surface. The cartilage, where it is not covered by the false membrane, is unchanged in structure. The membrane generally adheres with some firmness to the ulcerating surface; in other instances it is loosely applied to it; but, in all, the latter is accurately moulded to the former. (p. 17–19.)

The view given by KEY, of the usual mode in which cartilage is absorbed, or as it is commonly called, ulcerates, is in the main similar to that held by WILSON, but more fully and more satisfactorily developed. Its correctness I cannot doubt, for I have seen it, I think more than once or twice, from the first commencement, in which, on carefully lifting up the new membrane, its perfect impress is perceived upon the cartilage, varying in depth and extent according to the thickness and size of the membrane, till the entire depth of the cartilage is removed and the membrane comes in contact with the bone, the articular surface of which is also destroyed either by it or by simultaneous inflammatory action set up in the cancellated structure of the bone. The preparations to which I allude are in St. Thomas's museum, and some of the patients were under my own care.—J. F. S.

"When *suppuration*," KEY continues, "*follows acute inflammation, from a wound of the synovial membrane*, the latter undergoes that change which enables it to perform its new function. The surface becomes highly vascular, and, in most parts, covered with a new deposit of adhesive matter, which adheres firmly to the synovial membrane. The new surface is irregular, wanting the polish of the original membrane, and appears in many parts villous, or furnished with vascular fringed projections. In a joint thus far advanced in disease, the only mode of arresting the disease, or of repairing the mischief occasioned by the inflammation, consists in anchylosis. To this end, the removal of the cartilage is an essential step; and it would appear that the office of removing it devolves on the inflamed synovial membrane. The cartilage, under these circumstances, is not only eroded at the edge where the synovial membrane is reflected upon it, but grooves and indentations may be traced in various parts of it, having no connexion, as in the progressive strumous form of ulceration, with the edge of the synovial membrane, and not showing any indications of a new membrane forming on its surface. The means by which this ulceration is effected appear to be the newly organized surface of the synovial membrane in contact with the parts in which absorption is going on. To those who will carefully examine joints in this condition, the evidence of this will, I think, be sufficiently conclusive. The absence of all action in the cartilage, and the total want of vascularity in those parts, where ulceration appears to be most active, were the circumstances that first led me to look for some agent in the work of ulceration. The ulceration evidently begins on the surface of the cartilage, and not on that side next to the bone. It presents merely an eroded surface; there is no disorganization of its texture in the parts where absorption is about to take place; there is no previous degeneration of the cartilage into its primary fibrous structure, as may be seen in other forms of ulceration; but the cartilage seems to have lost part of its surface, as if it had been dug out, the remaining part appearing healthy, and presenting no trace of increased vascularity. The grooves are found only in those parts of the cartilage that happen to be opposed to the fringed and vascular synovial membrane; and these highly organized portions of the membrane may be seen to be closely adapted, and even to fit into the grooves in the cartilage. Those parts of the cartilage that happen to be in contact with another cartilaginous surface present no signs nor trace of ulceration, but appear to the eye perfectly healthy, and in texture firm. The process exhibits the closest analogy to that by which nature removes dead bones; the same inactivity or passive condition of the parts absorbed; the same suppurative action from the vascular granulation; and a similar degree of vascularity bestowed upon the newly organised structure which has to perform the office of absorption. It is not, however, in every instance of suppuration in a joint, even where this villous membrane is found, that ulceration of the opposite cartilage is to be looked for as an uniform occurrence; for strumous joints are occasionally examined, in which the synovial capsule has been for many months distended with purulent secretion, and the synovial membrane covered with flocculi hanging into the joint, without a trace of ulceration in the opposite cartilaginous surface. This exception rather favours the view which I have advanced of the ulcerative process in the case of suppuration from wound. The condition essential to the act of absorption is here wanting. There is not a wound or opening by which the pus can escape as fast as it is secreted: it consequently collects in the cavity of the joint, and, by distension, prevents the membrane coming in contact with the cartilage; and the villous projections from the membrane, even when the vessels are well filled with fine injection, do not exhibit that degree of vascularity which is so clearly developed when ulceration of the cartilage takes place. (p. 234–37.) Nature, it seems, does not often adopt this mode of removing the cartilage. It is only in the acute form of inflammation, as in wounds of joints, that I have observed it. The process of removing the cartilage appears at all times, and under all circumstances of disease, an object that she endeavours to accomplish; while the cartilage remains entire, anchylosis, the natural cure in some forms of diseased joint, cannot be effected; and, therefore, we may often observe ulceration of cartilage going on very early in those diseases that, forming some defect in the patient's constitution, cannot be arrested without anchylosis. (pp. 239, 40.)

Brodie (*a*), however, still considers that "the explanation which **Key** has offered does not admit of a general application, and that the absorption of the cartilage, commencing on the surface towards the cavity of a joint, may take place under such circumstances, that it cannot be supposed to be the result of any other agency than that of the vessels of the cartilage itself. (p. 331.) In speaking of ulceration of the articular cartilages, as a conseqnence of inflammation of the synovial membrane, I have not endeavoured to explain the exact nature of the process by which such ulceration is effected, and simply for this reason,—that I have not been able completely to satisfy my own mind on the subject. There can be no doubt that, in many instances, ulceration begins at the margin of the cartilage, where the synovial membrane is reflected over it from the neighbouring bone, or from the inter-articular ligaments, where such ligaments exist; but it may still admit of a question, in what manner the ulceration is accomplished; whether it be from the inflammation extending directly to the cartilage itself, or to the bone first, and the cartilage afterwards; or whether, according to the views entertained by Mr. **Key**, the latter, being altogether in a passive state, becomes absorbed by the action of the vessels of the fringed processes of the synovial membrane lying in contact with it. But there are other cases of inflammation of the synovial membrane, in which ulceration begins in the centre of the cartilage, so that none of these hypotheses afford any reasonable explanation of it. It seems not improbable that, in some of those cases which are usually regarded as examples of simple inflammation of the synovial membrane, the inflammation may not have been confined (even in the first instance) to this individual part, but may have begun simultaneously in all the textures of the joint. This is in conformity with what is observed to happen occasionally in the eye and other organs; and, under such circumstances, it is no more than might be expected, that, as the inflammation subsides, the cartilage should ulcerate either in the centre or in some other part of its surface. Nor is this a merely speculative opinion; at least I am much mistaken if it be viewed in that light by any one who, after having perused the history of the following case, considers what would probably have happened if the patient had not died of another disease before there was time for the disease in the joint to have run its course. A gentleman, about twenty-five years of age, had laboured for several years under a disease of the brain, in consequence of which he had been in a state of complete helplessness and imbecility. In the summer of 1820 he became indisposed otherwise: there was a cluster of enlarged glands in the left groin, and a purulent sediment was deposited by the urine. I was now desired to see him in consultation with Dr. **Maton**, who was his ordinary medical attendant. Soon afterwards, it was observed, that there was a general tumefaction of the left thigh and nates, and the patient complained of pain in certain motions of the limb. Under the treatment employed, the tumefaction subsided; but, immediately afterwards, a violent attack of diarrhœa took place, under which he sunk, and died on the 29th July. On examin-

---

(*a*) Additional Notes on Ulceration of Cartilage; in the Third Edition of his book on the Diseases of Joints, 1834.

ing the body we discovered an abscess, which seemed to have had its origin in the cellular membrane of the pelvis, near the neck of the bladder, which had burst into the neighbouring portion of the urethra, and which had also extended upwards on the left side, so that it could be traced as high as the mass of enlarged glands in the groin. The whole of the muscles surrounding the left hip-joint, were preternaturally soft and vascular, and so altered from their natural condition, that they could be lacerated by the slightest force. They also were to a considerable extent detached, or separated from each other, apparently in consequence of a serous fluid which had been effused between them, but of which nearly the whole had become absorbed. The capsular ligament and synovial membrane of the joint were of a red colour, and unusually vascular; and the cartilages covering the head of the femur and lining the acetabulum were also red and of a soft consistence, giving to the fingers a sensation somewhat resembling that which is produced by touching velvet." (p. 336–39.)

A very remarkable instance of ulceration of cartilage in an almost incredibly short space of time is mentioned by LAWRENCE (*a*). In a case of phlebitis, after bleeding, which came under his own care in St. Bartholomew's Hospital, the patient had pain in his knee, commencing on the fourth, and he died on the eighth day of the same month. "On examination after death I found the knee-joint filled with pus of a reddish colour, that is, with pus rendered red by the admixture of blood. The synovial membrane which had produced this pus was highly inflamed, but the articular cartilage of the femur and the corresponding articular surface of the tibia were completely destroyed, and this high degree of ulceration had been produced within the short period mentioned." (pp. 482, 3.)

He also mentions the following very curious circumstance:—"When necrosis attacks the shaft of a long bone, though it does not involve the ends, yet the mortification extends (or rather may extend ?—J. F. S.) sufficiently to the extremities to excite inflammation and absorption of the cartilages, although the synovial membrane does not become involved." And he speaks of a case in which "the whole shaft of the thigh-bone had perished, and the cartilages were as completely removed as if they had been cut out by the knife." (p. 483.) This appears to me the condition, though much more advanced, to which KEY refers, when, having spoken of the vascular deposit on the synovial membrane that destroys cartilage, he proceeds:—"A membrane is sometimes seen in joints under different circumstances, and affords a contrast to the above, as well in structure as in office. I allude to that adventitious membrane that is formed from the edges of the synovial membrane, in consequence of inflammation of a joint, induced by a contiguous disease of bone, as necrosis. In this case the membrane is formed for the purpose of circumscribing the cavity of the joint, when the cartilage is destroyed by the extension of the disease. It possesses but little vascularity, is smooth on its surface, not being furnished with the villous texture necessary to the ulcerative function. The opposed cartilage, under these circumstances, appears entire, ulceration taking place only on the surface next to the bone, and the membrane has not any connexion with the surface of the cartilage." (pp. 226, 27.)

Although it appears that, under inflammation, either chronic or acute, the less or greater deposit of coagulable lymph from the synovial membrane, which becomes organized, absorbs or eats up the cartilage with which it is in contact, as has been so ably described by KEY just quoted, and often requires amputation of the limb to tranquillize the constitutional excitement of the patient, which, if continued, would wear out his powers and destroy him; yet is it not to be considered as always a destructive, but rather, as KEY (*b*) has very truly stated it to be, "a repairing process, established with a view to the ultimate anchylosis of the joint, and by an efficient provision to prevent an inflammatory process that would otherwise end in ulceration and suppuration. A membrane is gradually developed by the agency of which the cartilage is absorbed, and which afterwards becomes the medium of anchylosis; thus the destruction of the joint is often prevented." (p. 146.)

HENLE agrees with KEY as to the absence of vessels in cartilage, but he explains its wasting or ulceration as dependent on want of nutriment. The following are his observations on the subject:—"As cartilage has not vessels it is not subject to any disease which depends on unnatural movement of the blood, neither inflammation nor hypertrophy; for the same reason, as it needs no vessels, it is not so easily wasted by pressure as bone * * * Cartilage only wastes when the current of blood into the tissue upon which its nutrition depends is interrupted; the diseased cartilage, as for instance of inflamed joints, therefore is destroyed as if by maceration, rough, then as it were eaten, and finally dissolved." (p. 809.)

(*a*) Lectures on Surgery; in Lancet, 1829-30, vol. ii.

(*b*) Med.-Chir. Trans., vol. xix.

Of Ulceration of Cartilage.—This, the more rare mode in which destruction of cartilage is effected, really occurs in the cartilage itself, and is described by Key (*a*) as "an action altogether different from absorption, and analogous to the softening of the intervertebral substance," in other words, "the result of disorganization of texture." (p. 135.) But before stating his opinions on this subject it will be advisable to mention his views on ulcerations in general, for the better comprehension of their application to cartilage. "Ulceration is a process analagous to the softening attending suppuration; it is a degeneration of tissue, a change in the affinities existing between its component parts, by which it becomes changed from a solid texture to a fluid inorganic mass. It differs from gangrene in being a vital action; while gangrene, by at once producing death in a part, prevents any such change taking place. In gangrene the supply of blood to the part altogether ceases, while the integrity of tissue is preserved; under ulceration the circulation in the vessels continues during the action, and the part still belongs to the living mass, and remains under the influence of vital action until its separation is completed." (pp. 137, 38.)

"Ulceration of cartilage," says Key, "is effected in the same manner as an ulcer in soft parts; it is a destructive action that sooner or later is followed by suppuration of the joint. It commences in the structure of the cartilage itself, which, no longer under the influence of those forces that unite its integral parts, breaks up, and becomes converted into a purulent mass, which, mixing with the synovia of the joint, irritates the synovial membrane to inflammation, and ultimately to suppuration and ulceration. Ulceration of cartilage, however, as a primary disease, is a much less frequent occurrence than absorption through the intervention of membrane. I do not remember," says Key, "to have examined a joint, that had been the subject of ordinary chronic inflammation, in which this membrane was not more or less developed. Nor have I seen an instance of chronic inflammation, in the early stage of strumous disease, in which degeneration or ulceration of the cartilage existed as the primary action. Chronic inflammation, however, after existing for many months or years in strumous subjects, may, and often does, become acute, and ulceration sometimes, in such cases, supersedes the absorbing process, and abscess rapidly forms. * * * Nature endeavours, so long as she can, to remove the cartilage by absorption, in order to prevent the necessity of suppuration; for primary ulceration of cartilage leads to the formation of abscess. The breaking up of the tissue of the cartilage is equivalent to the suppurative process in softer tissues; it creates a product that must be got rid of; the synovial membrane is irritated, and ulceration with abscess is the result. In absorption of the cartilage through the intervention of the membrane, suppuration is not a necessary attendant, and we sometimes find the whole process completed without abscess. But where the membrane is wanting, the process is analogous to the degeneration of soft parts, and is sooner or later followed by suppuration. * * * The diseases in which the texture of the cartilage primarily undergoes ulceration are, for the most part, acute from their commencement. The inflammation that follows wounds of joints often leads to the rapid ulceration of the cartilage, and to burrowing abscess. In these cases, the cartilage is found often to be extensively destroyed, and the bone laid bare, without any appearance of a membrane for the purpose of absorption. The remaining cartilage sometimes exhibits different stages of approaching disorganization; in some parts retaining its natural form, consistence, and appearance; in others being soft and spongy, or even pulpy; and in those parts most advanced towards ulceration, the fibre of the cartilage can be seen to separate, and flakes here and there appeared to be almost detached. * * * The chronic inflammation of the synovial membrane, attended with absorption of the cartilage, not unfrequently becomes acute from accidental causes, and, leading to ulceration, quickly disorganises the joint. Both ulceration and absorption may here be seen to operate. In some parts may be seen the membrane adhering to the cartilage or to the denuded bone, in various degrees of activity or vascularity, according as its office is completed or in progress; and in others a total loss of the cartilage may be observed, without the development of a membrane. It is not unusual for one half of a knee-joint to be losing its cartilage by absorption, while, by a process of inflammation subsequently excited, the other is in a state of active ulceration. On one side the cartilage is furnished with the absorbing membrane, which sometimes spreads over the whole of that side of the cavity, and protects it from the devastating process of ulceration that is at work on the other side of the joint, which is filled with pus and the remains of the disorganised cartilage. In persons who have become extremely irritable and weak, the ulcerative process is so determined, that the membrane itself is sometimes found in a state of ulceration." (p. 146–50.)]

(*a*) Med.-Chir. Trans., vol xix.

217. On examination of the joint after death, produced by other diseases, it has been found, if the disease were still in its commencement, that the cartilage, at one or more places, was loosened into a fibrous mass, and ulcerated; at a later period there was great destruction of the cartilage, the joint was filled with ichor, the synovial membrane and other parts of the joint disorganized.

Many will not allow the possibility of primary affections of the cartilage, as the cartilages of a movable joint must be considered as lifeless parts, which cannot take on inflammation, do not feel the effect of irritants, and, in affections of the synovial membrane or of the bony tissue beneath it, only suffer destruction and exfoliation. **Schumer** (*a*) has, in his experiments on animals, observed the same results as **Dörner** and others had previously, that the joint-cartilages, laid bare, injured, and even exposed to the air, never showed any trace of inflammation, which appeared only in the bony epiphyses and synovial membrane. **Gendrin** (*b*) supports this opinion especially on the ground of the cartilage not being covered with synovial membrane; an assertion which though also put forth by others is contradicted by observation. J. B. **Marc** (*c*).

According to **Brodie**'s and my own observations, I must consider the disease here described as different from common inflammation of the synovial membrane and of the spongy ends of bones, even although perhaps it does not always arise as a primary affection of the cartilage, but is caused by *partial* inflammation of the synovial membrane, and of the spongy bony tissue beneath the cartilage. **Meckel** (*d*) also supposes that the cartilage in different diseases of the joints may redden, swell, soften, and loosen up, but with this peculiarity, that suppuration is not necessarily connected with their ulceration.

[Sufficient has been already said in the last paragraph to prove, as seems to me, the truth of **Wilson**'s and **Key**'s notion of the deposit of a new and vascular substance upon the synovial membrane being the usual cause of ulceration of cartilage, and that the cause is not in the cartilage itself. It will not, therefore, require again to be adverted to further than to observe that it is quite distinct from the "loosening of the cartilage into a fibrous mass," spoken of in the present paragraph.

This form **Brodie** speaks of thus:—"We find occasionally some portion of the cartilage covering bone, altered from its natural organization, converted into a number of ligamentous fibres, each of which is connected by one extremity to the bone, while the other is towards the cavity of the joint" (p. 113); and as he soon after mentions in the dissection of one such case, "having no lateral connexion with each other" (p. 119); producing the "brush-like projections of the cartilage and synovial membrane," as **Mayo** calls them (*e*). This "conversion of the cartilage into soft fibrous structure," **Brodie** says, "I am disposed to believe is the frequent, though not constant, forerunner of ulceration. In a woman who died a week after a severe contusion of the hip, the cartilage of the hip was found in some parts entirely absorbed, in others having a fibrous appearance, similar to what has been described. And I have noticed the same circumstances in other cases sometimes connected with, and sometimes independent of local injury." (p. 121.) Here, then, is a morbid alteration of structure, the occurrence of which seems to indicate that there must be such a vascular apparatus entering into the formation of cartilages as enables new materials to be deposited and old materials to be absorbed, and without which morbid alterations of structure do not take place in other parts of the body." (p. 113.) **Brodie** (*f*) further observes:—"The degeneration of the cartilage into a fibrous structure is no uncommon circumstance; and I suspect that it is *one* cause of the crackling of the joints, which is not uncommonly met with in persons somewhat advanced in life. I have no doubt that it often exists where it is never followed by ulceration; but I am also well assured that, in many other instances, it precedes, and, in fact, forms, the first stage of the disease." (p. 339.) In regard to this "degeneration of the cartilage of a joint into a fibrous structure," which **Key** holds as a distinct form, and describes as the third mode of ulceration of cartilage, he says:—"As far as my observations have enabled me to judge, it is a disease of a peculiar character, and differing in many respects from the ordinary affection of joints that end in the destruction of the cartilage. I have had but few opportunities of verifying by dissection the

(*f*) Additional Notes.

existence of this disease. **Brodie** has described it, and appears to regard it as a not uncommon occurrence; in one instance he found it combined with disease of the intervertebral substance. Of three cases that have come under my notice, two have occurred in subjects brought into the dissecting-room, and the history of which I was unacquainted with; the other case was that of a gentleman who was labouring under stone in the bladder, and suddenly experienced a severe attack of pain about the head of the fibula and the bursæ at the back part of the head of the tibia. The pain was accompanied with considerable fever, and slight swelling of the parts in which he complained of the pain. On the third day the pain shifted from the fibula to the knee-joint, which swelled, as if from an effusion of synovial fluid. The suffering now became excessive, and the fever assumed a typhoid character. At the end of ten days from the commencement of the attack he died. The bladder presented less evidence of the inflammatory action than might have been expected from the intensity of his sufferings. The knee-joint was distended with a thin opaque synovial secretion, of a somewhat purulent character; the surface of the synovial membrane presented here and there patches of more than ordinary vascularity. The cartilaginous surfaces of the bones were entire, with the exception of a small spot on the end of the femur, which appeared ragged and irregularly broken up into a fibrous mass." (pp. 241, 2.)]

218. This disease shows itself in every age, but especially in children; more frequently in the hip and shoulder than in other joints. Its causes are external injury, but especially dyscratic diseases.

["The ulceration of the articular cartilages may," according to **Brodie**, "occur at any period of life, but it is most frequent in those who have passed the age of puberty, and who are under thirty-five years of age. We meet with it, however, some times in young children, and at other times in old persons." (p. 151.)]

219. The prognosis is always unfavourable, as the disease is often mistaken at its commencement, and speedy destruction of the parts of the joint is produced.

220. In severe irritation of the joint, leeches, cupping, even blood-letting, warm baths, and so on, must be employed at the onset. If the inflammation be thereby diminished, or if the disease has originally taken an insidious course, derivative remedies, and, among these, issues especially and the actual cautery are to be employed. The action of these remedies is often very rapid; the suppuration must, however, be kept up from the surface for a long time, and the joint kept perfectly at rest. Sometimes improvement quickly takes place; but the attacks recur, in which case, probably, suppuration has already taken place in the joint. When abscesses are formed, they must be treated as already directed, and especially the general diseased condition of the body somehow connected with the disease of the joint, properly attended to.

D.—OF THE INFLAMMATION OF THE JOINT-ENDS OF BONES.

221. The inflammation, in these cases, (*Inflammatio Processuum Articulorum*, Lat.; *Entzündung der Gelenk-Enden der Knochen*, Germ.; *Inflammation des Extrémités Articulaires des Os*, Fr.,) begins in the very vascular spongy part of the joint-end of the bone, and is at first accompanied with little pain, which comes on imperceptibly. After a lapse of time of uncertain length, there appears an elastic, irregularly spreading swelling of the outermost parts of the joint, the form of which depends on the expanded joint processes: the swelling is larger when the joint is in action, and smaller when it is at rest. The motions of the joint are little interfered with. After a shorter or longer time, increased pain comes on, the external skin becomes dusky red, and finally breaks; ill-conditioned pus is discharged, and caries is felt on using a probe. So often as some

wounds close, others break out, and hectic fever threatens to exhaust the patient.

[" There is another malady," says BRODIE, " which affects the joints, having all the character of scrofula, generally occurring in persons who have a scrofulous appearance, and usually preceded by, or combined with, scrofulous symptoms. In this disease of the joints, the cancellous structure of the bone is the part primarily affected; in consequence of which ulceration takes place in the cartilages covering their articulating surfaces. The cartilages being ulcerated, the subsequent progress of the disease is, in many respects, the same as where this ulceration takes place in the first instance." (p. 226.) The morbid affection appears to have its origin in the bones, which become preternaturally vascular, and containing a less than usual quantity of earthy matter; while at first a transparent fluid, and afterwards a yellow cheesy substance, is deposited in their cancelli. From the diseased bone we see, in some instances, vessels carrying red blood extend into the cartilage. The cartilage afterwards ulcerates in spots, the ulceration beginning on that surface which is connected to the bone. The ulceration of the cartilage often proceeds very slowly. I have known a knee amputated on account of this disease, in which the cartilage was absorbed for not more than the extent of a sixpence. Occasionally a portion of the carious bone dies and exfoliates. As the caries of the bones advances inflammation takes place of the cellular membrane, external to the joint. Serum, and afterwards coagulable lymph, is effused, and hence arises a puffy and elastic swelling in the early, and an œdematous swelling in the advanced, stage of the disease. Abscess having formed in the joint, makes its way by ulceration through the ligaments and synovial membrane, and afterwards bursts externally, having caused the formation of numerous and circuitous sinuses in the neighbouring soft parts. In one case, thin layers of cartilage were found lying on the ulcerated surface of bone, apparently unconnected with it. In some instances, in the advanced stages of this disease, we find nearly the whole of the cartilage forming an exfoliation instead of being ulcerated. This scrofulous affection attacks those bones, or portions of bones, which have a spongy texture, as the extremities of the cylindrical bones, and the bones of the carpus and tarsus, and hence the joints become affected from their contiguity to the parts which are the original seat of the disease. Sometimes, however, we may trace the effects of these morbid changes even in the shaft of a cylindrical bone; so that we see the femur or tibia converted in its middle into a thin shell of earthy matter, enclosing a medullary canal of unusual magnitude. It has been remarked by a modern author (*a*), that in the last stage of this disease the bones not only lose the preternatural vascularity which they possessed at an early period, but even become less vascular than healthy bone. I believe the observation to be correct; and this diminution of the number of vessels, and, consequently, of the supply of blood, is probably (as this author has suggested) the proximate cause of those exfoliations which sometimes occur where the disease has existed for a considerable length of time, especially in the smaller bones." (p. 245–48.)

Upon this condition, his " last form, in which ulceration (or rather absorption) of cartilage takes place," KEY (*b*) observes:—" There are two forms of disease in bone under which this secondary absorption of cartilage takes place; the one is of a chronic nature; the other assumes an acute form; but in the process of ulceration the same passive condition of the cartilage may be observed as in that which commences within the cavity of the joint.

The *chronic* form is that in which a strumous action takes place in the cancellated structure," (pp. 243, 44,) and is that just described. " I apprehend," says KEY, " that most pathologists will concur in the probability of the loss of the cartilage being effected by means of the vascular granulations that spring up from the cancelli, and appear to form a continuous structure with the surface of the cartilage. In making a transverse section of the joint, under these circumstances, there is no trace to be seen of increased vascularity in the cartilage, nor in the synovial membrane, until the action is far advanced, that can lead us to suppose that the cartilage was ulcerated by any other agent than the vascular tissue of the bone.

The *acute* form of the disease differs from the former in the comparative suddenness of the attack, as well as in the appearance which the bone presents. The former is like all strumous affections, slow in its progress, and at first marked by little or no pain in the part. Months often elapse before the symptoms become severe, and the constitution much affected. But in the acute form of disease attacking the spongy extremities of bones, the pain is often severe in the beginning, the limb at that part tender when pressed, and the constitution a good deal disturbed. A few weeks only elapse

---

(*a*) LLOYD on Scrofula, p. 123.

(*b*) Med.-Chir. Trans., vol. xviii.

before the joint exhibits symptoms of participating in the mischief. From this time the disease makes rapid progress: if suppuration takes place in the cavity of the joint, the synovial membrane ulcerates and allows the matter to burrow between the muscles of the limb: fistulous openings at length form, and tend in some measure to abate the patient's sufferings. The effect, however, on the constitution is such that amputation is usually resorted to for the preservation of life. Examination of the joint exhibits very different appearances from those which are observed in the chronic strumous disease of the bone; not in the cavity of the joint itself, for here the process of destruction is in some respects the same; but in the bone the affection is found to be altogether of a different character. The substance of the bone retains its firmness of texture; and when cut through shows no signs of disease except at one part of the cancelli. There a cavity is found containing one or more portions of detached bone, surrounded with pus; this cavity is found to communicate with the joint by a fistulous opening of small size, which may sometimes escape observation. The cancellated structure of the bone surrounding the cavity usually appears natural and sending forth vascular granulations. The cartilage covering the end of the bone is extensively ulcerated in some parts, whilst in others it appears to have undergone no change. The process of ulceration evidently begins on the outside of the joint, for the cartilage, when closely examined, appears to be undermined, and the surface towards the joint where this undermining process is going on seems quite sound. The synovial membrane shows signs of acute inflammation, and its cavity is found to communicate with one or more extensive collections of pus above and below the joint. This form of disease is in its nature analogous to necrosis of the shafts of the cylindrical bones." (p. 245–47.)

"In scrofulous disease of the cancellated texture of the heads of bone," says Goodsir, "or in cases where the joint only is affected, but to the extent of total destruction of the cartilage over part or the whole of its extent, the latter is, during the progress of the ulceration, attacked from its attached surface. Nipple-shaped processes of vascular texture pass from the bone into the attached surface of the cartilage, the latter undergoing the change already described. The processes from the two surfaces may thus meet halfway in the substance of the cartilage, or they may pass from the attached, and project through a sound portion of the surface of the cartilage, like little vascular nipples or granulations. The cartilage may thus be riddled, or it may be broken up into scales of various size and thickness, or it may be undermined for a greater or less extent, or be thrown into the fluid of the cavity of the joint in small detached portions, or it may entirely disappear." (p. 19.)]

222. According to the stage of the disease, the joint ends are found on dissection in different conditions. They are soft, broken up, dusky red; their vessels much enlarged, and the cells of the bone are filled with reddish lymph. The cartilages are often still unchanged externally, but their inner surface is loosened from the destroyed bone. In the most advanced stage, both bone and cartilage are destroyed, the synovial membrane and ligaments disorganized, and the cavity of the joint filled with ichorous pus.

223. This disease is more rare in the hip and shoulder than in other joints, and most frequent in the spongy bones of the wrist and instep. It is more frequent in children and young persons than in adults. Its occasional cause may be external violence, but there is always dyscratic disease, and especially scrofula, in causal connexion with it.

[Brodie says:—"The scrofulous affection of the joints occurs frequently in children; it is rare after thirty years of age. Examples of it occur in almost every joint of the body; but the hip and shoulder appear less liable to it than many other articulations." (p. 248.) But Key states:—"The bones in which he has observed this (the chronic) form of disease are the small bones of the carpus and the extremity of the femur; and, more frequently, the head of the tibia and the bones of the tarsus. Persons of *all* ages appear to be liable to it: I have witnessed it," he says, "in patients from the age of two years to fifty." (p. 244.)

Brodie also further observes:—"As it depends on a certain morbid condition of the general system, it is not surprising that we should sometimes find it affecting several joints at the same time, nor that it show itself in different joints in succession, attacking a second joint after it has been cured in the first, or after the first has been removed by amputation. It is seldom met with, except in persons who have the marks of what is called a scrofulous diathesis; and in many cases it is either preceded, attended, or followed, by some other scrofulous symptoms, such as enlargement of the scrofulous glands of the neck, and mesentery; or tubercles of the lungs. I have often been led to believe that the occurrence of this disease in the joint has suspended the progress of some other, and perhaps more serious, disease elsewhere." (pp. 249, 50.)

Brodie's last observation is, I am convinced, exceedingly correct, if, as I presume, he means some modification of scrofulous disease in other parts of the body. I am certain that I have, again and again, seen persons, whose appearance betokened incipient phthisis, recover, and become stout and healthy; as if the disease had proceeded to its crisis in the joint, and, on the removal of which by amputation, all the constitutional disturbance ceased.—J. F. S.

Brodie considers that "the scrofulous disease is more likely to be confounded with ulceration of the articular cartilages than with any other. There is, in many respects, a correspondence in their symptoms. There are, however, certain points of difference, and I believe that this difference will be found in general sufficient to enable the practitioner, who is careful and minute in his observations, to make a correct diagnosis; at least, in those cases in which the local disease is not so far advanced, and in which it has not so much affected the general constitution as to make the diagnosis of no importance. (p. 250.) The principal difference which is to be observed between the symptoms which have been just described, and those which are met with, where ulceration of the cartilages occurs as a primary affection, is in the degree of pain which the patient endures, and which is much less in the cases of the former (the scrofulous disease) than in those of the latter description. It may, indeed, be matter of surprise that, in cases of this scrofulous affection, the sufferings of the patient should be so little as they are found to be in proportion to the quantity of local mischief. For the most part, the pain which he experiences is not a subject of serious complaint, except at the time when an abscess is just presenting itself underneath the skin, and then it is immediately relieved by the abscess bursting. There is never that severe pain which exhausts the powers and the spirits of the patient in cases of ulceration of the cartilage, except in a very few instances, and in the most advanced stage of the disease, when a portion of the ulcerated bone has died, and, having exfoliated so as to lie loose in the cavity of the joint, irritates the parts with which it is in contact, and thus becomes a source of constant torment. There are other circumstances, besides the less degree of pain, which, although not in themselves sufficient, it is useful to take into the account in forming our diagnosis, such as the general aspect and constitution of the patient, and his having manifested a disposition to other scrofulous symptoms; the very tedious progress of the disease; and the circumstance of the suppuration not being in general confined to a single collection of matter, but producing a succession of abscesses." (pp. 255, 6.)]

224. The prognosis and treatment are the same, as already stated, in inflammation and ulceration of cartilage.

[OF THE FAVOURABLE CONSEQUENCES OF ULCERATION OF THE CARTILAGES.

224.* The termination of ulceration of the articular cartilages from whatever cause, although generally destroying the patient by wearing out his constitutional powers, unless prevented by the removal of the limb, is neither always fatal, nor does the joint or its motions even seem to be always destroyed. When the destruction of cartilage has a favourable issue it terminates in one of two ways. In the *first*, the cartilage is replaced by a layer of ivory-like bone, and the motions of the joint continue; this especially happens in disease of the hip-joint. In the *second*, the opposed ends of the bones are united either by a ligamento-fibrous structure, which permits a slightly yielding motion of the joint, or by bone which precludes any motion, and thus are produced the two forms of anchylosis, viz., the soft and the hard. Whether the one kind passes into the other, I can not positively state, though I think I have seen, in more than one instance, part of the connecting medium ligamento-fibrous and part bony.

I. Of the *ivory-like covering of the joint surfaces of bones.* This condition has been by some anatomists thought to be merely a natural process, the common consequence of age, by which the cartilage thick in youth is gradually thinned in adult age, and finally in advanced life completely removed, bone being stated to be constantly deposited in its place till the whole surface of the joint is thus covered. I think, however, I shall be able to show that this is an erroneous statement, as at the very onset it would appear unlikely that more earthy matter should be deposited. under natural circumstances, upon the ends of bones, so as to give those parts an ivory-like character, whilst on every other part of the same organs less earth is deposited, and even the fibrous mould in which it is lodged becomes thinner and thinner in age.

"The removal of the cartilage from the heads of bones in old people," observes **Key**, "proceeds so slowly that it is difficult to say, on the examination of a joint, whether the action has ceased, or is still in a state of progress. The form of disease to which I allude is attended with a good deal of stiffening of the joint, accompanied by what are termed rheumatic pains. The place of the cartilage is often supplied by a bony deposit, resembling ivory in texture as well as appearance." (p. 242.) **Toynbee** says:—"The articular cartilage is gradually being converted into bone during the whole of life; thus it is thicker in young than in adult subjects; and, as Sir B. **Brodie** informs me, it is much thinner in old age than in the adult: in fact, it is not very rare to find that the articular cartilage of the head of the *os femoris* in very old persons has completely disappeared, a change which is probably to be attributed to its entire ossification." (p. 167.)

That this is merely a natural process as might be inferred from **Toynbee**'s observation cannot be admitted; were it so, the disappearance of the cartilage and the ivory-like covering of the joint-end of bones would be much more frequent than it is. It is quite true that the cartilages of elderly people are much thinner than those of young persons; but this does not depend on their conversion into bone, for the shell of bone in the aged is commonly as much attenuated in comparison. It ought also to be commonly happening in all joints, which is far from the case, as it is but rarely found except in the hip-joint. For these reasons I think **Brodie**'s opinion is correct, that "it is probable in these cases the original disease had been ulceration of the cartilages." And especially as he mentions what appears to me to be the two stages of this ivory-like appearance, the *first* being that which he speaks of as having "many times in dissection observed a portion of cartilage of a joint wanting, and in its place a thin layer of hard, semi-transparent substance, of a gray colour, and presenting an irregular granulated substance;" and the *second*, that in which "no remains of cartilage were found on the bones of one hip; but, in its place, a crust of bony matter was formed, of a compact texture, of a white colour, smooth, and having an appearance not very unlike that of marble." (pp. 204, 5.) The difference of the two appearances seems to me easily explained by the continual motions in the joint wearing down the irregular granulated surface till the white, smooth, marble-like condition is produced. That it is also a consequence of absorption of the cartilage I think is further proved by the expansion of the articular surfaces, which is very often noticed in the hip-joint under this form of disease, both the head of the thigh-bone and its socket being also flattened; which flattening and spreading of ball and socket, or of hinge-joints, very frequently occurs with ulceration of cartilage without any ivory-like deposit, and as commonly when soft anchylosis exists. This then is the first and most favourable result of ulceration of cartilage, in which the motions of the joint are not materially impaired.

II. Of *Anchylosis*.—"This is an union of bone with bone," says **John Hunter** (*a*), "which ought not to be united, and is of two kinds, one by soft parts, the other by bone. In inflammations of joints we often have adhesions by a soft medium. Very considerable inflammation is necessary to produce anchylosis in joints, and much time is necessary for their perfection, as we see in white swellings. The adhesions are sometimes partial, sometimes universal. The soft is from two modes, viz., adhesion and granulation. The soft only can take place where there is naturally no intermediate substance, and the joint is surrounded by capsular ligament. Bony anchylosis I shall divide into five kinds, four of which are in the surrounding parts by ossific inflammation, the other by an entirely new substance between the extremities of a bone." (p. 521.) With the first four kinds we have at present nothing to do, but the fifth kind is the immediate object of our attention, viz.,

Anchylosis effected "*by the whole substance of the articulation.*"

This is of two kinds, and these are the only ones which can admit of the soft anchylosis. It is somewhat similar to the union which takes place in soft parts; it arises from two causes, 1*st*, from inflammation of the parts themselves; 2*ndly*, from the inflammation of the surrounding parts, the parts themselves partaking of it.

From the *first cause*, or inflammation of the parts themselves, arises "*suppuration in*

(*a*) Lectures on Surgery, **Palmer**'s Edition.

joints producing anchylosis. This is of two kinds," says **Hunter**, "viz., the truly inflammatory, and the scrofulous; the former we shall now treat of.

"If the inflammation be carried on, an abscess is formed in the cavity as in any other part; and the suppuration is more universal in the cavity than in other parts, being diffused through the whole. This continues to approach nearer and nearer the external surface, and either breaks or may be opened. So far as they are connected with bone, they are similar to compound fractures, but the suppuration is slow, and takes place with difficulty, and then generally falls into the natural scrofulous disposition, which renders it tedious. The suppuration is then imperfect, appearing to partake of both the adhesive and suppurative. The ulcerative disposition is slow in bringing the matter to the skin, which arises from the indolence of the prior suppurative disposition and inflammation. The ulcerative inflammation sometimes goes on, so as entirely to alter the joint, that is, the receiving cavity becomes larger and the received part less; this is often the case in the hip-joint. These cases then become very tedious, and generally very uncertain in their cure. Before they are opened they are generally become so indolent that opening has very little effect, and often, when scrofulous, such a disagreeable inflammation comes on as to destroy the patient, and therefore amputation had better be performed at once, if this disagreeable inflammation does not take place immediately after opening; yet a fistulous opening is generally the consequence.

"*Soft anchylosis from granulations.*—A joint so healed has no cavity left; the surfaces uniting. A joint coming to suppuration from not being resolved in the first mode, but forming granulations, is more tedious than in the soft parts, and the powers of restoration in them are very weak.

"*Bony anchylosis* takes place when the granulations ossify, so that the two bones are united into one, exactly similar to a compound fracture. But when the suppuration is healthy the joints sometimes recover; in such cases the matter is sooner discharged, and the parts are more disposed to return into their original state." (pp. 522, 23.)

Such is **John Hunter's** account of this important process, to which, however, some exceptions must be made. He seems to wish it inferred, that anchylosis generally results from suppuration of joints, for he has elsewhere observed, that "Nature is very little disposed to take on adhesive inflammation, because the necessary consequence would be loss of motion in a part originally intended for motion." (p. 519.) And that granulations as the consequence of suppuration produce anchylosis either soft or bony. I am not, however, disposed to assent generally to these statements, though I would not deny their occurrence as exceptions.

In the first place, as regards the frequency of *Soft Anchylosis from granulations* following suppuration, I feel assured, from frequent observation, that soft anchylosis is produced by the adventitious membrane poured out during inflammation of the synovial membrane, which, as **Key** (*a*) says, "produces ulceration of the contiguous cartilage," (p. 224,) and, "when the cartilage has been wholly absorbed, and the ulcerative process has been checked by the inflammation being arrested, serves another purpose: it becomes the medium of union between opposed surfaces of bone, or the means of anchylosis. Long after all inflammation has subsided, one of the condyles of the femur is often found adhering to the tibia by means of this membrane, which appears white and ligamentous, a layer of cartilage often remaining between the membrane and the bones, as if the process of ulceration had been arrested." (p. 226.) And I believe, most commonly, when the soft anchylosis so originating is completed, that no suppuration in the joint takes place, and that, when it does happen, it results from recent inflammatory action assuming the suppurative character, and set up by external violence, which, destroying the cartilage down to the surface of the bones, these also ulcerate; and then, if there be sufficient constitutional power, the bones produce the granulations, and these inosculating, union of the opposed surfaces is produced, as seen in **Mayo's** case below, (p. 246,) and as in compound fracture, by deposit of earthy matter in the granulations, and thus bony anchylosis is brought about. I think this will be shown to be a correct view of the subject on examination of the cases which will be presently mentioned. Hip disease, which is also almost invariably attended with suppuration, and more or less complete destruction of the cartilage, and even of the head of the thigh-bone and its socket, seems to me a further proof of the opinion I have advanced, as at that joint soft anchylosis is very rare; whilst, on the contrary, bony anchylosis, if the patient's strength enable him to battle out the disease, is almost the constant favourable issue of the contest.

Key states, that "the formation of the vascular membrane frequently takes place without suppuration, as may be seen in strumous joints that have been the subject of chronic inflammation for years, without abscess having formed; and the inflammation

---

(*a*) Med.-Chir. Trans., vol. xviii.

is sometimes confined to one side of the joint. Such joints are sometimes seized with an acute attack of inflammation of that part which had been previously healthy; suppuration rapidly ensues, under which the failing of the patient's health and powers demand amputation of the limb for the preservation of life. The two sides of the joint present different appearances: one shows no recent signs of inflammation; the ends of the bones are partially, perhaps wholly, deprived of their cartilage, or the cartilaginous surface is ulcerated only to a certain depth; between the bones is seen the membrane adhering to the cartilage, white, possessing scarcely a trace of vascularity, and merely serving to connect the ends of the bones by means of what is termed ligamentous anchylosis. The other side of the joint is full of pus; every tissue in a state of active inflammation; the cartilage removed by a rapid process of ulceration, in which the bone is probably found to have taken an active part; and the ends of the bone are seen covered with vascular fungous granulations, from which pus is abundantly secreted." (pp. 227, 28.) With the correctness of these remarks I fully concur, and the following instances well support them, excepting that, in the first, the pus had been discharged, and, in the second, ulceration had occurred without suppuration.

Case 1.—B. S., aged nine years, a fair-haired strumous boy, became my patient in June, 1840. Five years ago he was attacked with swelling and lameness of the left knee, without any known cause; he was put under medical treatment, and afterwards was admitted into the hospital, from which, about four years since, he was discharged; and it may be presumed all active disease had ceased, as his mother was told that the knee, which had become much bent, with the heel much raised from the ground, would be restored, as his health recovered. No such improvement, however, has taken place, and he has since gone about constantly on a crutch. Being a very active boy, he has frequently got falls, and hurt his knee; which, however, in the course of a few days have been recovered from. Within the last two months he has fallen twice, but has not got well as previously; and though during the day his knee has been little painful, yet at night it has become so much so as to prevent his sleeping.

The leg is now bent nearly at a right angle with the thigh; it can be bent a little more, but not straightened; the great toe only touches the ground, but he cannot bear upon it. The knee is rather larger than natural, especially the inner condyle; and both condyles project a little over the front of the head of the shin-bone. There is a little fulness above the knee-cap, as if the joint were distended; but there is little tenderness, and gentle motion does not cause pain.

During a month nothing was done except keeping quiet; and it was observed that, if he did not move about during the day, he had not any pain at night. The joint then seeming to be perfectly free from irritation, I thought it advisable to attempt straightening the leg, sufficient to bring the foot down and render the limb useful. A hinge-splint, adapted to the bent state of the limb, was, therefore, adjusted to the back of the leg and thigh, which it was purposed slowly to extend by a screw, the two ends of which were affixed to the two portions of the splint. This practice was continued for some weeks without benefit; but swelling coming on, attended with pain and tenderness, it was discontinued, and amputation successfully performed in the September following.

On examination, the whole joint was found largely covered with fat; and immediately above the knee-cap an abscess, about the size of a shilling, communicating with the joint below the front of the outer condyle by a narrow passage an inch long, lined with adhesive matter, but not containing pus. There is not any dislocation, but mere bending of the leg upon the thigh-bone. The cavity of the joint was destroyed, and the opposed bony surfaces united with fibrous matter, but some of the cartilage still remained.

Case 2.—J. P., aged nineteen years, a dark-haired scrofulous lad, came under my care in November 1839. Eight years ago, whilst running, he felt a sudden snap in his left knee-joint, and almost immediately a swelling appeared above the base of the knee-cap, rather larger than a pigeon's egg, but unattended with pain. This on the following morning had subsided, but another swelling presented itself on the inside of the ham, which was at once blistered by his medical attendant. On the next day he was attacked with bilious fever, which confined him to bed fifteen weeks, and reduced him very much; but during this time he did not suffer any pain or inconvenience in his knee. Soon after getting about, the knee began to swell and to become stiff, but unaccompanied with pain, and not preventing his walking. Leeches were once applied, and an evaporation lotion used, but nothing more done; and at the end of a twelvemonth, the knee having become fixed in a straight position, he was told he had a white-swelling, and the removal of the limb advised, to which, however, he would not submit. His health continued improving, and he walked about with the aid of a stick, without pain, or further inconvenience than a little halting, as late as July last, when he took a walk of fourteen miles without annoyance. At the latter end of the following month (August) he slipped on a stone, and fell on his side, at the same time bending the previously fixed knee. At the moment he had little pain; but when he went to bed the pain came on, and has recurred nightly ever since. Little swelling followed, but he could no longer bear on the limb without pain, which was also excited when pressure was made on the knee-cap. On first getting up in the morning, the leg shakes very much, and causes great pain in the knee; but both subside in a few minutes, and he has not any more pain till he again goes to bed, when it recurs, and much disturbs his sleep. His general health is good.

The knee-joint is now but little enlarged, and there does not appear to be any fulness from fluid in the joint. The leg is partially bent, the condyles of the thigh projecting much over the head of the shin-bone, and the knee-cap seems nearly fixed on the front of the outer condyle. The whole knee is generally tender, but especially upon the inner side. When the bones are pressed together he suffers pain, and a slight grating is felt. Amputation was performed, and he recovered.

Upon examination, the whole exterior of the joint was found covered with much fat, especially in the ham, and on the inside of the tip of the knee-cap was a small abscess, containing a tea-spoonful of thick greenish-yellow pus. Within, the knee-cap was found adhering by bone to the outer condyle of the thigh-bone, and the latter was connected by fibrous tissue with the outer articular surface on the head of the shin-bone; but the greater portion of the hind part of the condyle was absorbed. The cartilage upon the inner condyle was partially destroyed, and the surface of the bone exposed; upon the corresponding part of the head of the shin-bone the cartilage was almost entirely destroyed, and the bone itself ulcerating.

Whether the fibrous anchylosis be the first step to bony anchylosis, I am not prepared to say; but the following instance in which the limb was amputated between thirty and forty years after the motion of the knee had been destroyed, for necrosis in the condyle, produced by a comparatively recent injury, would lead to the belief that the two diseases were distinct.

Case 1.—S. D., aged fifty years, a sickly woman, came under my care in October, 1839. When ten years old she fell down an area on her right knee, which immediately swelled and became painful; suppuration ensued, and pus having been discharged on the outside of the thigh and knee, after a time she got comparatively well, being able to tread on the entire sole of the foot; but she has never since had free motion of her knee, though capable of bending it to some extent. Twenty-three years since suppuration of the joint again occurred shortly before one of her confinements, and from that time a sinus on the fore and upper part of the inner condyle has continued discharging. Three years ago she received a blow with a heavy boot, just above the knee-joint, which suppurated and burst, an inch or two above and on the outside of the base of the knee-cap. From this time her health failed, and, though after lying in bed for nine months she was able to go about her usual occupations, yet during the last year the pain in the knee again became so severe that she has been constantly confined to her bed. She has now one sinus near the outer hamstring, a little above the knee-joint, and other three about the inner condyle, from which there is a free discharge. The condyles project forwards, as if the ligaments of the knee had given way, and partial dislocation had taken place. Motion of the knee-joint does not cause much pain, but she has frequent dull aching pain just above the knee, both day and night, which occasionally extends up to the hip, and is brought on whenever attempts are made to put the foot to the ground. Her health is much broken; her appetite bad, and she gets but little sleep. Under these circumstances, amputation above the knee was performed, and she did well.

Upon examination, by making a vertical section of the bones, the recent disease was ascertained to consist in a sequestrum as large as the top of the thumb in the expanded part of the thigh-bone, which was enlarged just above its articular surface; the front of the shell of the bone was here absorbed, forming an aperture as big as a sixpence, which communicated with the wound above the knee-cap, and with the lower wound on the inner condyle; the sequestrum, which was quite loose in the cancellated structure of the bone, might have been easily removed by dilating the former wound. The popliteal space of the thigh-bone was quite bared of its periosteum, and communicated with the upper two wounds in the inner condyle. Of the *primary disease* there were the following traces:—The joint surfaces of the thigh and shin-bone connected by fibrous structure; the front of the head of the latter destroyed, and in its place a patch of fibrous matter; the bottom of the condyles destroyed, and in several parts the remaining articular surface deprived of its cartilage; both condyles were partially dislocated forwards upon the head of the shin-bone. The semilunar cartilage remained on the outer, but not on the inner side. The knee-cap was not anchylosed.

The following is a similar instance, but of much shorter duration, and strengthens my opinion of the long existence of the fibrous structure just mentioned.

Case 2.—E. B., aged thirteen years, a fine boy, but of strumous appearance, became my patient in December, 1839. Five years since, but without any injury, he had some affection of his right knee-joint, accompanied with much pain and drawing up of the heel, so that he could not put the whole sole of his foot upon the ground. He was not, however put under medical treatment till the lapse of six months; but the knee became more and more bent, and about two years since the leg was so much drawn up that the foot would not reach the ground. About this time an abscess, doubtless connected with the joint, burst just above the outer condyle, from which pus was freely discharged, and the pain he had previously suffered diminished. The wound became sinuous and has so continued to the present time.

The leg is *now* bent upon the thigh at an acute angle, beyond which it cannot be straightened, though it may be bent up to the thigh with a little pain. The condyles of the thigh-bone project in front of the head of the shin-bone, which rests entirely on the hind articular surfaces of the former. The knee-cap is sunk between the condyles, and between it and the head of the shin-bone is a large fluid cushion, painful on pressure, and occupying the place of the ligament, which seems completely destroyed. Upon the inside of the knee there is also tenderness.

Amputation above the knee was performed, and he did well.

On examination of the joint, a sinus was found extending around the outer condyle to the knee-cap, behind which was some scrofulous matter. All the articular surfaces were connected by fibrous structure, but some portions of cartilage still remained. Within the epiphysis of the head shin-bone was a small portion of dead bone, but not communicating with the joint.

That soft or fibrous and bony anchylosis may occasionally, though rarely, happen at the same time I do not deny, as they are shown to do so by the following

Case.—J. M., aged forty-two years, a stout healthy sailor, was put under my care in May, 1838. Two years ago he was attacked suddenly twice or thrice, without assignable cause, with numbness of the left leg and knee, and inability to stand upon it for four or five minutes, after which he moved about as freely as usual. In August of the same year he caught violent cold, was very sick, and his knee began to ache constantly, accompanied with shooting pain. Soon after he was unable to bend the joint at all without excessive pain. In the following month, his leg having become perfectly straight and incapable of motion without great pain in the knee, the inside of which was very tender, he was admitted into the hospital. He was then freely leeched, cupped, blistered, and had his mouth kept sore for a long while. Under this treatment the active stage of the disease passed by, but the leg gradually became half bent by his own effort to render his position more easy, and I could not ascertain whether it could be then straightened. It was however determined to attempt anchylosis in the bent posture, and the limb was therefore put on an Amesbury's apparatus, where it was kept for several months. In the May of the year following, anchylosis being presumed to have taken place, the apparatus was removed, and he walked on crutches, the toe touching the ground; but he could not bear on it without having pain in the knee. As his home was at the sea-side it was thought advisable that he should go there; but after remaining about six weeks, he came up to another hospital where he continued for three months, during which time a screw apparatus was applied for the purpose of straightening the limb, but no benefit resulting, he went home in the following September.

He has now come to me to have amputation performed, as though the joint is quite fixed and but little larger than the other, he is still unable to walk without crutches, cannot bear upon the limb, and if he accidentally strike the toe, has severe pain in the knee. His general health good. On the second of June I amputated through the thigh, but he died three weeks after of peripneumony and ulceration of the mucous membrane of the bowels.

On dissection of the joint it was found covered with fat, and the ligaments had degenerated into a sort of half-fatty, half-cartilaginous structure. A vertical section made on the inner edge of the knee-cap and from before to behind presented a firm anchylosis, which appeared bony on the sides, and specially on the inner side of the joint. The hinder half of the condyles being destroyed and the knee half bent, the thigh at its truncated part rested on the head of the shin-bone, but not immediately, as a quantity of dense fatty fibrous tissue was interposed between them. This new structure was about half an inch thick behind towards the ham, but in front it thinned and became sharp, so as to have a wedge-like shape. Where the articular surface remained there was a thin layer of cartilage. The knee-cap was anchylosed by bone to the outer condyle, but its edge, where unapplied, still exhibited a trace of cartilage. On clearing off the half-fatty half-ligamentous structure into which the ligaments had been converted, the ends of the bone were found close together and not separated as within. There was a slight indication of cartilage between them on the exterior, but on the interior of the joint the union seemed to be bony. The posterior ligament was undistinguishable, being involved in the fibrous mass between the thigh and shin bone. In front of the thigh-bone at top of the pulley for the knee-cap, there was a slight remnant of what was probably synovial membrane, but it was little vascular.

Of the *second cause* or inflammation of the surrounding parts, in which the parts themselves partake of it, JOHN HUNTER gives the following

CASE.—A lady had an inflammation come on from the opening of a sacculus mucosus on her elbow, which inflammation was very violent and extended to the joint, soon after which she lay in and died of puerperal fever. On opening the joint, soft union was found to have taken place, which, if she had lived, would probably have become bony, and the joint would have been anchylosed, merely from adhesive inflammation." (p. 522.)

The following very similar instance is given by MAYO (*a*):—

CASE.—" A young man had a lacerated wound of the ankle; ten days after erysipelas had supervened, and matter had formed about the joint; the integument sloughing, an opening could be seen into the fore and outer part of the ankle-joint, the cartilage of which became rapidly absorbed. The patient suffered severe pain, which he described as gnawing, throbbing pain, with occasional violent shootings through the joint, and a distressing sense of grating when the limb was disturbed. The patient's strength declining rapidly, amputation was thought necessary. The limb was removed two months after the accident.

" Upon a vertical section being made of the ankle, one common change was found to have taken place in both the joints, which the upper and under surfaces of the astragalus contribute to form. In each of these joints the cartilage had entirely disappeared; and the denuded ends of the bones were joined together by a layer of semitransparent and organised lymph, from a sixth to a quarter of an inch in thickness. This union by lymph was a step towards union by bone. One circumstance appeared to me of peculiar interest. The interior of the bones was perfectly healthy, but the surfaces to which the lymph adhered, were for the depth of one or two lines, extremely vascular. They combined with that vascularity the roughness of surface and softness of texture described as found upon the articular aspect of bone in the third kind of ulceration of cartilage, specified above. (p. 228.) I conclude, from hence, that long anchylosis may, under favourable circumstances, take place after that form of ulceration of cartilage, which depends upon inflammation of the adjacent surface of the bone." (pp. 68, 9.)

Bony Anchylosis may occur in any joint, either by the conversion into bone of the cartilages forming symphyses, as in those connecting the pelvic bones together, which can scarcely be called disease,—1st, by the conversion of ligament and fibro-cartilage, as in the anterior and crucial ligaments, and the intervertebral substance of the spine, which scarcely at all differs from ossification of the symphyses just mentioned, instances of which are far from uncommon in elderly persons as regards all the vertebræ, except the two uppermost, which, however, in very rare cases, are also in like manner not only united by bone to each other, but also to the occipital bone, of both which conditions we have examples in St. Thomas's museum; in these the articular surfaces have been deprived of their cartilages either by ulceration or ossification, and the true joints destroyed by bony union: 2dly, by conversion of the ligamentous capsules alone into bone, the contained joints still existing; this occurs in the capsules of the articular processes of the vertebræ, and is not to be confused with that just mentioned. I am not aware that it happens on any other joints. One or other, or all these forms together, are found in elderly persons.

But the most important form of bony anchylosis is that which I have mentioned above, and produced, as I believe, from the granulations of the joint-ends of bones, the cartilaginous covering of which, as well as the articular surfaces, having been destroyed by suppuration, whether arising from acute or from scrofulous inflammation; and thus circumstanced, " the two bones are," as JOHN HUNTER observes, " united into one exactly similar to compound fracture." This kind of anchylosis is undoubtedly most common in the hip-joint, where the inflammation seems to run more readily into suppuration than in any other joint; it is next frequent in the bones of the wrist and instep, but least usual in the elbow, knee, and shoulder; indeed, as regards the latter, anchylosis is, under any circumstances, rare. Instances of anchylosis, even of the lower jaw to the temporal

(*a*) On Ulceration of the Cartilages of Joints, and on Anchylosis; in Med.-Chir. Trans., vol. xix.

bone, have been mentioned by the older writers; and of late, CRUVELHIER (*a*) mentions the case of an old woman who had anchylosis of the right condyle of this bone, the result of a blow received when a child.

In these cases the greater part, if not the whole, of the articular surfaces are removed, and the cancellated structure seems continuous from the one to the other bone.

Other kinds of anchylosis are mentioned, as where bones are fractured into joints; but, so far as my observation has gone, I have not noticed this fact. It is quite true that often when a fracture extends into a joint, the motions of the latter are destroyed, but this generally depends on the displacement of the joint surfaces. Anchylosis is also said to occur when, from any cause, a limb has been kept in one position for several years, and the attitudal penances of the Indian fakirs have been quoted as examples; I presume, however, that in these cases there is not union of the joint surfaces, and that the fixation of the joint simply depends on the rigidity which the muscles have acquired from being long retained in the same position, instances of which, though in minor degree, are of daily occurrence, in the stiffness of uninjured joints which have been long kept in one posture during the cure of fracture, and to restore their perfect freedom of motion is often a very tedious process, and occasionally even not to be effected.

As regards the *treatment* of anchylosis, if it be of the soft or ligamento-fibrous kind, attempts for its relief may be made either by passive motion or by the use of a hinge-splint, the hinge of which is to be placed in the bend of the joint, and its two parts bandaged to the corresponding members of the limb, which is very slowly to be moved, two or three eighths of an inch daily, as the patient can bear it, by means of an iron rod, each end of which is provided with a male screw acting in a female screw, sunk in a movable but shorter rod attached to each portion of the splint; or passive flexion may be performed frequently during the day with the hand alone. In employing either method, however, special care must be taken to relieve the stress on the joint by taking off the apparatus, or to leave off passive motion, whenever pain occurs in the joint, as that indicates at least a disposition to inflammation, which, if increased, may be productive of very serious consequences.

As adjuncts to these immediate remedies, covering the joint with warm brewer's grains, or friction, may be employed to promote relaxation; but, if pain be excited by either, it must not be persisted in.—J. F. S.

VELPEAU (*b*) has considered ably, and at great length, the treatment of complete anchylosis in reference to the three modes proposed for its relief, viz., 1st, the cutting out a wedge-shaped piece of bone; 2ndly, the establishment of a false joint; 3rdly, the violent and sudden rupture of the anchylosis.

The *first* operation was proposed by BARTON (*c*), one of the surgeons to the Pennsylvania Hospital, Philadelphia, U.S., performed a bold and successful operation for the relief of an anchylosed hip, in a young sailor who had fallen down a ship's hold, and had not any surgical assistance for seven months. The injured thigh, which was the right, was bent, with the knee drawn across the left femur; the outer edge of the foot was placed forwards, and the sole turned outwards, which circumstances led to the presumption of dislocation; but there was so much swelling and so great pain on making any attempt to discover it, that it was left alone. After these symptoms had subsided the limb was put in an apparatus for some weeks, but no relief was obtained, and anchylosis took place. After the lapse of a year BARTON determined to attempt an artificial joint, for which purpose he made in the upper part of the thigh an incision six or seven inches long, with its middle corresponding to the great trochanter. A second incision was made across the centre of the former at right angles, and four or five inches in length. The cuts were continued down to the bone, so as to expose its front and hind part between the great and little trochanter, after which the bone was sawn through between the great trochanter and the neck. The limb was then readily restored to its natural position, and found to be only half an inch shorter than the other. The case did extremely well, and, at the end of four months, the patient could walk a considerable distance, and he could by that time carry the foot twenty-four inches forwards, twenty-six backwards, twenty laterally, and rotated it six inches inwards or outwards. The same operation was performed a second time (*d*), with success, by BARTON, on a young physician, but on the lower part of the thigh, for anchylosis of the knee; and subsequently by GIBSON of Philadelphia, also in anchylosis of the knee.

The *second* operation consists "in laying bare the bone, and sawing it in such a way as to interrupt its continuity; and, for the purpose of preventing union, it must be

slightly moved from time to time, and all other means used likely to produce a false joint; by degrees the two ends of the bone grind against each other, and the movable end rounds and becomes blunted, whilst the other hollows slightly. The muscles soon adapt themselves to this new joint, and in the end permit the patient to use the limb as previously." **Velpeau** is favourable to this operation, from the motions occurring in false joints caused by ununited fractures. "As to the danger of the operation," says he, "it is much less than those of amputation or resection of the bone." (pp. 200, 201.) Two operations of this kind have been performed with success upon the thigh; the first by **Barton**, in 1826, who cut through and detached all the soft parts about the great trochanter, and then divided the bone with a small saw; after which the limb was placed on **Dessault's** extending splint. The second was performed by **Rodgers** of New York, in 1830, and also did well.

The *third* operation, viz., that of breaking through the anchylosis, was practised and recommended by the older surgeons; but **Velpeau** does not favour it, and mentions a case, referred to by **Amussat** (*a*), of anchylosis of the knee-joint, in which "an attempt was made to restore motion by bending the leg suddenly upon the thigh. A painful cracking was immediately heard in the knee, and very soon alarming abdominal and thoracic symptoms occurred, which in a few days destroyed the patient." **Velpeau** thinks that "if the union be but slight, or so dispersed that some little motion is permitted, prudence allows the anchylosis to be broken either suddenly or gradually; if the deformity be so great as to render walking or standing impossible without assistance, but not if the contrary be the case; * * * the rupture of the anchylosis being then, really difficult to effect, dangerous, and success by no means certain, as there is always a tendency to the reproduction of union. * * * Attempts only are justifiable when the limb is in such a state of flexion or deviation that its use is prevented. And if the patient earnestly require it, the operation may be performed, *but never if the knee-cap adhere to the thigh-bone.*" And he well observes that "the adherence of the knee-cap to the front of the condyles of the thigh, when existing alone, does not appear to have sufficiently attracted the attention of practitioners. The action of the extensor muscles of the leg is destroyed thereby, and thus the flexors, deprived of their antagonists, gradually drag the head of the shin-bone into the ham, and bend the leg. It matters little that the mobility of the rest of the joint remains, or that it is by any means restored, the anchylosis of the knee-cap continues an insurmountable obstacle to the restoration of the functions of the knee-joint. (p. 204–206.) When the knee-cap is movable, and there is simply false anchylosis, the subcutaneous division of the ligaments or tendons is preferable to the sudden rupture of the anchylosis, because it is infinitely less dangerous and painful, and has at least as favourable a result. * * * If it be a true anchylosis, it would be better, in the greater number of cases, to do nothing at all. It may, however, be necessary, for some reason or other, to choose between the violent and sudden rupture, the wedge-shaped section of the bone, and the establishment of a false joint. Of the latter two operations I have already spoken. As to the rupture, if the soldering of the knee-cap is such as to render dislocation of the shin-bone backwards very probable, we should only operate at the urgent entreaty of the patient, and after having laid before him or his friends the chances of what may happen. This operation is indicated if the flexion be not directly at a right angle, if the knee-cap be not so fixed as to leave little hope of its being detached, or if even it be so situated that, notwithstanding its union, the shin-bone can be brought back beneath the thigh-bone." (pp. 234, 35.)

The apparatus (*b*) by which the rupture of anchylosis is effected was invented by **Louvrier**, and is thus employed:—"The patient, seated on a padded table, is confined in that position by a laced thigh-bandage, fastened to the front of the table by a strong strap, and to the thigh by the lace and some straps and buckles, the thigh being protected from pressure by wadded pads, and a roller lightly applied. The foot is then enclosed in a half boot, laced in front, the sole of which, near the heel, has a metal mortise of two inches, to receive the middle of a metal bar, seven or eight inches long, having at each end a little copper wheel, by which, during the extension, the leg can be directed on a double inclined ascending plane. In the groove of the mortise is attached and fixed one of the pulleys of the winch upon which the extending cord is wound. The thigh and leg are then to be confined in a sort of leather gutter, which is closed in front by straps and buckles, and has on each side, long stout steel splints, those on the outer side jointed together at the top of the knee, and taking at first the same angle as the anchylosis, the one corresponding to the thigh and the other to the leg; the inner splints are also similarly connected. To render his apparatus most effective,

---

(*a*) Revue Médicale, vol. ii. 1831.

(*b*) Dictionnaire des Dictionnaires de Médecine, vol. i. 8vo. Paris, 1840.

Louvrier thinks it necessary to make upon the thigh, at the knee, direct pressure from before backwards, and to push it in that direction, whilst the leg is extended. This is effected by means of two uprights fixed on each side of the knee, by their lower ends upon the splints, the four upper ends of which are connected by a rectangular parallelogram, in which they are enclosed and retained by copper nuts. A thick pad is placed on the knee, and, between the metallic rectangle and this compress, a cushion formed of a plate of metal, and padded towards the thigh. The limb thus fixed is placed in a rectangular wooden gutter, at the end of which is a winch; within these planes is a chase, on which the foot, supported laterally by the bar attached to the sole, travels. A set of cords attached to these parts connects them with the winch, and with a few turns of its handle, the leg is straightened always in less than a minute, and most commonly, when the anchylosis is angular, with one or two distinct and successive cracks." (p. 396.)

Velpeau evidently is no favourer of this apparatus; and he enumerates among the objections to its employment, the severe pain, but as this is very short it may be borne with; and the violent purulent inflammation of the joint which may ensue, the danger of this, however, is exaggerated. But the more serious accidents are laceration of the integuments of the great arterial or venous trunks; of the nerves and ligaments; and the more or less severe bruising of the soft parts, in consequence of which sloughing occurs. "If, however," says he, "we observe the cases (about twenty) on which Louvrier has operated, there are but few in which symptoms, more or less serious, occur immediately. I know, however, that these facts are still too few; at present we may presume that this plan of treatment is not so dangerous as one might be led to suppose." (p. 208–15.) To the question "What benefit is the patient to derive from this treatment?" Velpeau replies, as regards the re-establishment of the motions of the joint, that neither theory nor Louvrier's facts are favourable. To prevent the reunion of the bone frequent motion must be resorted to, which is dangerous; but if not employed the bones become resoldered, and the leg either becomes straight, with the sole of the foot flat on the ground, (which is the most favourable result,) or the limb continues more or less bent, and the foot cannot be put flat, so that the patient needs crutches. Another result is, that the head of the shin-bone is thrown behind the condyles, and dislocation is produced, as, if the knee-cap be soldered to the fore and lower part of the condyles, which is often the case, it prevents the head of the shin-bone resuming its natural place, and, serving as a wedge, pitches the latter into the ham, so that a dislocation being produced the patient is not benefited by the operation. (p. 215–17.)

HYSTERICAL AFFECTIONS OF THE JOINTS.

Hysterical females are often subject to affections of the joints, especially of the hip and knee, which, without any actual disease in the part, produce excessive suffering, and are liable to be mistaken for dangerous ailments. Brodie, in reference to this point, says:—"At first there is a pain referred to the hip, knee, or some other joint, without any evident tumefaction; the pain soon becomes very severe, and by degrees a puffy swelling takes place, in consequence of some degree of serous effusion into the cells of the cellular texture. The swelling is diffused, and in most instances trifling; but it varies in degree; and I have known, where the pain has been referred to the hip, the whole of the limb to be visibly enlarged from the crista of the ilium to the knee. There is always exceeding tenderness, connected with which, however, we may observe this remarkable circumstance, that gently touching the integuments in such a way as that the pressure cannot affect the deep-seated parts, will often be productive of much more pain than the handling of the limb in a more rude and careless manner. In one instance where there was this nervous affection of the knee, immediately below the joint there was an actual loss of the natural sensibility; the numbness occupying the space of two or three inches in the middle of the leg. Persons who labour under this disease are generally liable to other complaints, and in all cases the symptoms appear to be aggravated, and kept up by being made the subject of constant anxiety and attention." (pp. 339, 40.) In an affection of this kind in the knee, Tyrrell (a) observes:—"The point which convinced me that the affection was not one of actual inflammation of the ligaments of the knee, but a sympathetic disease depending on the peculiar condition of the constitution, is this, that if she had inflammation merely of the internal lateral ligament and the posterior ligament, the pain would be confined to those parts, particularly when the limb was at rest, and she would complain of pain particularly on pressure on those parts; but when you examined the surface of the joint, it mattered little where you pressed, it was all the same, she complained of pain." (p. 316.) Bell (b) mentions a very remarkable case of hysterical affection, "in which there was great difficulty of discovering whether there was actual disease or not, in which the pelvis was pitched obliquely, as if there were disease in the hip. But there arose a class of symptoms which pointed to the right source, a singular contraction and retraction of the leg, so that the knee was bent almost to the bursting of the ligaments, and the foot turned in so extraordinary a manner, that the great toe lay close to the anus. The retraction was so powerful that we naturally apprehended that the ligaments of the joint must be destroyed. It proved to be a case of hysteria, and, what was extraordinary, was the resemblance it had in every feature to the disease of the hip-joint." (p. 297.) Coulson also mentions a case which he saw in St. Bartholomew's Hospital, in which "the patient was twenty-eight years of age, and had suffered from hysterical affections for ten years. The right heel was doubled under the thigh, the heel rested against the tuberosity of the ischium, and the great toe, as in the case just related, was close to the anus." (p. 117.)

(a) St. Thomas's Hospital Reports. (b) Medical Gazette, vol. xiv. 1833, 34

Coulson observes that, in this affection, "the affected limb is liable to remarkable alternations of heat and cold; at one part of the day the limb feels cold, and assumes a purple aspect; at another, hot flushes, followed by perspiration, break out over the extremity; again, the limb does not merely feel hot to the patient, but is actually so to the touch of another, and the whole capillaries of the affected part become turgid with excess of blood." (p. 117.)

Goodlad (a) objects to the term hysterical being applied to these affections, and says: "If after a careful examination of the hip, or of any other joint, and of the muscles connected with it, no adequate cause of pain can be discovered there, it surely becomes an imperative duty, and it is the only one remaining to ascertain whether any and what cause exists in the course of the nerves, and if there be no such cause discoverable, the practitioner may safely rely upon finding it where it very frequently, nay, by much the most frequently exists, viz., at the point of connexion which those nerves possess with larger masses of the nervous system; it matters not whether in the brain or in the spinal marrow, the same effects follow. The tenderness of the skin both here and on the spine may alike be disregarded; it is sometimes permanent, at others fugitive; but in either case it is an indication only where disorder may be found by tracing the nerves distributed on these parts to their origin." (p. 93.)

In these cases menstruation is generally either irregular or defective, and the bowels are torpid; the most important point, therefore, towards the cure consists in putting these matters to rights by constitutional remedies. Local applications, I do not think, are of much service; but Brodie says:—"The parts may be bathed with a cold evaporating lotion, or they may be enveloped in a plaster composed of equal parts of the extract of belladonna and soap plaster, an application which will be found of singular utility, not only in these, but in a great number of other painful nervous affections." (p. 340.) Goodlad thinks that, in addition to whatever may be deemed necessary for the general state of the system, local measures must be had recourse to, *not* applied to the *part where* the pain is experienced, but to the origin of the nerves distributed to it; and the greatest caution seems necessary that nothing applied there can give local activity to vessels already too active.—J. F. S.]

225. As we shall now consider these diseased conditions of the various joints, under the several names already mentioned, (*par.* 198,) we shall be able to show, by the difference of their course and the result of pathological anatomy, in what structure the disease has primarily developed itself. Thus, the various opinions which have been advanced with great partiality, as to the nature of these diseases, will be known to be well founded in particular instances, although their universal correctness is denied.

I.—IN THE HIP-JOINT.

(Coxalgia, Morbus Coxarum, Luxatio spontanea Femoris, Coxarthrocace.)

226. The symptoms of this disease exhibit three very well-defined stages, according as the inflammation has an *acute* or *chronic* character.

(a) A letter to Sir B. Brodie, containing a Critical Inquiry into his Lectures illustrative of certain local Nervous Affections. London. 8vo.

227. In the *Acute Inflammation* of the Hip-Joint, after any occasional cause, there arises sharp pain in the hip-joint, which extends on the inside of the thigh to the knee-joint, not increased by touching the knee if the thigh be undisturbed at the hip-joint, but increased by any pressure and motion of the hip-joint itself. The region of the hip, especially the buttock, is more or less swollen, consequently its wrinkles are mostly somewhat deeper; the thigh is drawn up towards the belly, because outstretching it is very painful; the foot is turned somewhat outwards, and cannot be moved inwards without pain. If the length of both extremities be compared, they are either *alike* or the diseased extremity is *seemingly shortened* or *seemingly lengthened;* both, however, only in a slight degree. Fever exists in proportion to the severity of the symptoms. Standing and walking are very difficult, or even quite impossible; the patient, therefore, throws the whole weight of the body upon the sound limb, draws up considerably the hip of the ailing side, bends the knee, and merely touches the ground with the tip of his foot.

[Key (*a*) says:—"The hip-joint is less frequently the subject of acute than of chronic inflammation, probably from being well protected from the influence of atmospheric changes, to which the knee and most other joints are exposed. In the adult, acute disease of this joint is occasionally seen, in which the whole structure of the joint, cartilage as well as ligament, undergoes complete disorganization in the space of a few weeks." (p. 230.)]

228. If the inflammation do not subside, it passes into suppuration, with an increase of all the general and local symptoms; collections of pus are formed within the joint as well as on its exterior; the fever assumes a hectic character, the powers sink, the patient wastes considerably, the muscles of the hip and thigh become flabby, and a careful measurement of both extremities shows that the diseased one is really lengthened. The abscesses become superficial around the joint, either in its immediate neighbourhood or at a distance from it; and, during this time or subsequently, when the abscesses have burst, the head of the thigh-bone escapes from the hip-socket, and is dislocated commonly upon the back of the hip-bone (*b*), so that the diseased extremity becomes considerably shortened, is rolled inwards, and appears somewhat bent at the knee-joint. The patient now either sinks under long continued hectic consumption, or, what is more rarely the case, the suppuration diminishes, portions of bone come away, and the apertures of the abscesses close.

229. In the *Chronic Progress of Inflammation* of the hip-joint, the three stages are, on account of the gradual development of the symptoms, more distinctly and determinately marked (1). In the beginning, the patient complains of slight pain in the hip-joint, of some weariness in the thigh and stiffness of the joint, especially in the morning, which subsides during the day, but is always increased by much exertion. The pain is not continuous; it often increases towards evening, with slight febrile excitement, and specially resembles rheumatic pain moving slowly about the thigh (2). At the hip-joint itself no disease is discoverable, except an increase of pain on pressure behind the great trochanter, or on the front of the joint where the femoral vessels pass beneath Poupart's ligament. These symptoms

---

(*a*) Med.-Chir. Trans., vol. xviii.

(*b*) I have presumed to use the ordinary English terms, hip-bone, haunch-bone, share-bone, and hip-socket, in preference to the Latin names, *ilium*, *ischium*, *pubes*, and *acetabulum*, and I purpose always employing English names wherever parts of the body possess them. I know no reason why we should be more ashamed of using our mother tongue than the Germans or the French, and I see no particular advantage in using the figurative Latin of the Schools.—J. F. S.

may continue, better or worse, for months or years, under a lingering course of this disease. The gait is merely trailing, and the foot commonly somewhat turned outwards.

[(1) **Brodie** says:—"I believe in the greater number of those cases to which the name of Diseased Hip has been usually applied, the ulceration of the cartilages is the primary affection, and the other parts in and near the joint become affected only in a secondary manner." (p. 137.) **Key** (*a*), however, holds a different opinion, and observes:—"The Hip Disease, emphatically so called, is a chronic affection, uniformly attended with ulceration of the cartilage;" and, from the cases which he has examined, he is induced to believe "that the ulceration is preceded by inflammation of the *ligamentum teres*." (p. 230.)

(2) It is somewhat remarkable that **Chelius** does not enumerate, among the symptoms of the first stage of hip-disease, the pain more particularly about the inside of the knee, which almost invariably exists, and being often the only pain noticed by the patient, has frequently led to mistake of the actual seat of the disease, and to the treatment of the knee as if that were the part affected. It indeed presents an example of **John Hunter's** (*b*) "remote sympathy," in which "there appears no visible connexion of parts that can account for such effects. In these cases there is commonly a sensation in the sympathizer which appears to be delusive, and produces a wrong reference of the mind to the seat of the disease." (p. 7.) This sympathetic pain in the knee is by some held to depend on irritation of the anterior crural plexus of nerves as it passes over the hip-joint; but Sir **Charles Bell** thinks the obturator nerve is the communicant. "The obturator nerve," he says (*c*), "passes through the thyroid foramen, down to the hip-joint, and, after supplying the muscles, is distributed upon the inner part of the knee. The nerve in its course is thus involved in the inflammation which affects the hip-joint, and the pain is referred to its extreme cutaneous branches, at a part distant from the seat of the disease." (p. 77.) **Coulson** does not agree with this explanation, as "very commonly we find the pain extending along the middle, and even outer part of the thigh, whilst the obturator nerve is distributed to the muscles of the inner side of the limb." He therefore suggests, that "from the intimate connexion of the long head of the *m. rectus femoris* with the outer edge of the acetabulum and with the capsular ligaments, the fascia of this muscle may take on the inflammatory action, and the pain in this way be conveyed down the limb to the thigh." (p. 3.) I prefer **Bell's** explanation, however; as certainly in the majority of the cases of diseased hip which I have seen, the pain is usually on the inside of the knee.—J. F. S.]

230. The second stage is characterized by a lengthening of the diseased extremity; the buttock of the affected side is flatter, its fold becomes deeper, the whole thigh is wasted and flabby, the great trochanter stands more upwards and outwards; every movement by which the surfaces of the joint are brought into contact is in the highest degree painful; the gait of the patient is very limping; the weight of the body rests entirely on the outstretched sound leg; the lengthened limb is bent at the knee, approached to the sound one, and the foot most commonly much everted. A peculiar sharp pain now comes on in the knee, which, however, usually retains its natural condition, only now and then being changed in its form, according to the observations of **Albers** and **Rust**. Although the pain in the knee is nearly always more severe than that in the hip-joint, yet the latter only is increased by direct pressure.

[**Astley Cooper** observes:—"The motions of the joint are impeded; extension is performed with difficulty; the child's knee is bent; and the heel, on the diseased side, scarcely touches the ground. Besides this incapacity for extension, great difficulty is experienced in the flexion of the joint. Thus if you attempt to bend the knee towards the abdomen, the child shrinks from the touch and complains of pain. If you throw something on the floor, and desire the child to pick it up, you will observe, that, in attempting to get possession of it, it bends only the sound knee. If you say, 'Let me see you put your foot on the chair,' the child does this readily enough with the sound leg, but is incapable of doing it with the other, in consequence of the confined state of the flexions of the joint. The rotation of the joint is also impeded, more especially the rotation inwards, which cannot be attempted without great pain and uneasiness. If the

---

(*a*) Med. Chir. Trans., vol. xviii. (*b*) On the Blood, &c. (*c*) London Medical Gazette, vol. i.

patient be laid down on his face, to examine whether the nates are lower on one side than the other; there is generally a difference of an inch or more on the diseased side." (pp. 454, 55.)

As to the mode of determining the special part of the joint which is diseased, Key (*a*) observes "the motions of the joint, that give the patient most pain, are strongly indicative of the seat of the affection. In the earliest stage, before the soft parts could well be affected, if the disease commenced in the cartilage, eversion of the thigh and abduction of the limb from the other produce the greatest degree of suffering to the patient, while he can bear the joint to be flexed, and to be slightly inverted, without complaining. A similar indication of the *ligamentum teres* being inflamed, is the pain sometimes expressed on pressing the head of the femur against the acetabulum; in its healthy state the ligament being lodged in the hollow of the acetabulum, receives but little pressure, but when it is swelled by inflammation, the cavity of the joint affords it less protection; and, when pressure is made by forcing the head of the femur upwards, the ligament is compressed, and usually produces some degree of pain. The circumstance, too, of the *ligamentum teres* being destroyed by ulceration, when the head of the bone and acetabulum are only partially ulcerated, may be considered as presumptive proof of it being very early engaged in the disease. There are few cases of *post-mortem* inspection of the hip-joint in an advanced stage of disease in which the *ligamentum teres* is not found destroyed." (pp. 232, 33)]

231. The disease gradually runs on to its third stage; the diseased extremity becomes shortened, either as a consequence of displacement of the head of the thigh-bone, or, if that and the hip-socket have been destroyed by caries, by the diminished head of the bone being drawn into the much expanded socket. Oftentimes the disease here terminates, the pain diminishes, and on the spot where the displaced head of the thigh-bone lies a hollow is formed, or the head of the bone being retracted into the socket is anchylosed to it, and the patient consequently recovers with an incurable lameness. Most frequently, however, in this stage a painful fluctuating swelling occurs about the whole hip-joint, which ultimately breaks, and a quantity of pus is discharged; the suppuration becomes bad; the probe introduced into the abscess openings indicates carious destruction, and the powers of the patient are worn out by hectic fever. But rarely do these apertures close; the suppuration then diminishes, pieces of bone are thrown off, &c. &c.

In order to measure accurately the length of the extremity during the progress of this disease, we examine it most satisfactorily, according to Fricke's method (*b*), in the following manner:—The patient being laid on a table covered with a woollen rug, an assistant fixes the pelvis, and places his thumb beneath the anterior superior iliac spine, for the purpose of steadying the skin. A painted tape, or a wooden measure furnished with two moveable pointed transverse pieces, and a Paris measuring-scale, is now to be applied above the thumb of the assistant upon the spine, and being there fixed the other part of the measuring instrument is to be carried down to, and immediately beneath, the outer ankle. The same measurement is repeated on the sound side. In the same manner then is the thigh measured, the measure being stretched to the upper end of the splint-bone; and then the leg alone, which is especially necessary if the patient be unable to straighten the leg.

[Abscesses of the hip-joint do not always burst externally. "Sometimes the abscess," says Astley Cooper (*c*), "breaks into the pelvis, at other times into the rectum, and a large quantity of pus is voided with the stools, which was the case with a young gentleman I attended; in another case it opened into the vagina; the lady was lame, but ultimately recovered." We have also a preparation at St. Thomas's museum, of which, however, I do not know the history, excepting that Astley Cooper used to mention it as a case in which abscess of the hip-joint, in making its escape, had ulcerated a small hole in the femoral artery, as that vessel passed over the front of the joint. Besides these, Coulson mentions a case in which matter had made its escape from the affected joint into the pelvis, so as to press on the neck of the bladder, and had caused

---

(*b*) Ueber Coxalgie und Coxarthrocace; in Annalen der chirurg. Abtheilung des allgemeinen Krankenhauses zu Hamburgh, vol. ii. p. 21.

(*c*) MSS. Lectures on Surgery.

paralysis of that organ. (I presume he means retention of urine.—J. F. S.) On examination after death, I discovered," says he, "that the matter had escaped through the acetabulum to the posterior part of the bladder, and had made a lodgment close to its neck." (p. 23.) **Samuel Cooper** quotes a case under Dr. **Mackenzie**, of Glasgow, of a lad of sixteen, who died of enormously enlarged liver; but, on dissection, a communication was found through the bottom of the acetabulum, between the cavity of the hip-joint and the colon, smooth, as if of long standing. (p. 869) **Scott** also mentions a case of this disease affecting both hips, and the abscesses communicated with the cavity of the pelvis on each side, through the acetabulum. (p. 106.)"

So great is the importance of Diseases of the Hip-Joint, that I think it advantageous to give at length **Brodie**'s account

Of the difference between the Hip-disease arising from Ulceration of the Cartilage, and that from Scrofulous deposit in the cancellous structures of the Bones.

As already stated, **Brodie** considers that ulceration of the cartilages is the primary affection in the disease to which the term Diseased Hip is usually applied, and that the scrofulous affection of the cancellous structure is less common in the hip and shoulder than in many other joints, and that these two diseases have many circumstances in common, but have certain points of difference which, in their early stages, admit of their being distinguished from each other by careful and minute observation, it will be advisable to give his account of the symptoms presented by each.

The occurrence of ulceration of the cartilages at any period of life, though most frequently between the age of puberty and thirty-five years, has been already noticed, (p. 236,) as has that of scrofulous affection occurring frequently in children, though rarely after thirty years of age. (p. 238.)

"When the cartilages of the hip are ulcerated, the only symptoms met with for some time are pain, and a slight degree of lameness in the lower limb. The pain at first is trifling and only occasional; afterwards becoming severe and constant. It resembles a good deal the pain of rheumatism, since it often has no certain seat, but is referred to different parts of the limb in different individuals, and even in the same individual, at different periods. As the disease advances the pain becomes exceedingly severe, particularly at night, when the patient is continually roused from his sleep by painful startings of the limb. Sometimes he experiences some degree of relief from pain in a particular position of the joint, and in no other. A patient in St. George's Hospital never obtained any rest except when he had placed himself on the edge of the bedstead, with his feet on the ground and resting on a pillow. As the pain increases in intensity, it is more confined in its situation. In the greater number of instances it is referred to the hip and knee also, and the pain in the knee is generally the most severe of the two. At other times there is pain in the knee and none in the hip. Sometimes there is pain referred to the inside of the thigh, sometimes even to the foot. Wherever the pain is situated it is aggravated by the motion of the joint; but it is aggravated in a still greater degree by whatever occasions pressure of the ulcerated cartilaginous surfaces against each other. Hence the patient is unable to support the weight of the body on the affected limb; and if he be placed on an even surface, in a horizontal position, and the hand of the surgeon applied to the heel, so as as to press the head of the femur against the concavity of the acetabulum, violent pain is the consequence, although this be done in so careful a manner that not the smallest degree of motion is given to the hip-joint. This circumstance is well deserving of attention; and no one should attempt to give an opinion as to the nature of a disease connected with the hip, without having made an examination in the manner which has been just described. Soon after the commencement of the complaint the hip-joint is found to be tender, whenever pressure is made on it either before or behind. The absorbent glands in the groin become enlarged, and sometimes suppurate. Occasionally there is a slight degree of general tumefaction in the groin. In this there is nothing remarkable, since we must suppose that a disease going on within the articulation must ultimately occasion inflammation in the neighbouring parts. But it is a curious circumstance, that in some cases there is tenderness of those parts, to which, though not diseased themselves, the pain is referred from sympathy with the disease in the hip. I have observed this in the knee several times, and I have also seen a slight degree of puffy swelling of this joint, where pain was referred to it in consequence of disease in the hip. * * * When the disease has existed for some time the nates undergo a remarkable alteration in their form. They become wasted and less prominent, so that, instead of their usual convexity, they present the appearance of a flattened surface; they are flaccid to the touch, and hang more loosely towards the lower edge, and they have the appearance of being wider than those of the other side. In a very few cases, in the advanced stage of the disease, the nates are really wider, in consequence of the acetabulum being filled with coagulable lymph and matter, and the head of the femur being pushed out of its natural situation. But in general the increased breadth of the nates is only apparent, and on an accurate measurement no difference will be found between the nates on one side and those of the other. The alteration in the figure of the parts, in those cases may arise partly from the position in which the patient usually places himself when he stands erect; but the principal cause to which it is to be attributed, is the wasting of the large fleshy bellies of the glutæi muscles, from want of use; and this has been ascertained by repeated and accurate examinations of the living, and numerous dissections of the dead body." (p. 153–57.)

"While the disease is going on in the cancellous structure of the bone, before it has extended to the other textures, and while there is still no evident swelling, the patient experiences some degree of pain, which, however, is never so severe as to occasion serious distress, and often is so slight, and takes place so gradually, that it is scarcely noticed. After a time (which may vary from a few weeks to several months) the parts external to the joint begin to sympathise with those within it, and, serum and coagulable lymph being effused into the cellular membrane, the joint appears swollen. The swelling is puffy and elastic, and though usually more in degree than it is, at the same period, in those cases in which the ulceration of the cartilages occurs as a primary disease, it is not greater in appearance, because the muscles of the limb are not equally wasted from want of exercise. I have observed that in children the swelling is, in the first instance, usually less diffused and somewhat firmer to the touch than in the adult. If a suspicion of some disease of the joint has not existed previously, it is always awakened as soon as the swelling has taken place. Should the patient be a child, it not uncommonly happens that the swelling is the first thing which the nurse or the parents discover. This leads to a more accurate inquiry, and the child is observed to limp in walking, if the disease be in the lower limb, and to complain of pain on certain occasions. * * * The swelling increases, but not uniformly, and it is greater after the limb has been much exercised than when it has been allowed to remain for some time in a state of quietude. As the cartilages continue to ulcerate the pain becomes somewhat, but not materially, aggravated. It is not severe until abscess has formed, and the parts over the abscess have become distended and inflamed. The skin, under these circumstances, assumes a dark-red or purple colour. The abscess is slow in its progress; when it bursts, or is opened, it discharges a thin pus, with portions of curdly substance floating in it. Afterwards the discharge becomes smaller in quantity, and thicker in consistence; and, at last, it nearly resembles the cheesy matter which is found in scrofulous absorbent glands. In most instances several abscesses take place in succession, but at various intervals; some of which heal, while others remain open, in the form of fistulous sinuses, at the bottom of which carious bone may be distinguished by means of a probe. (p. 250–53.)

The progress of the malady in both these forms of hip-disease are very nearly alike; in both is there the same reference of the pain to the knee rather than to the joint affected, the same alteration in the appearance of the nates, the same shortening of the limb from destruction of the head of the thigh-bone, or its dislocation, and the same production of abscesses. But the principal distinction is in the less degree of pain which accompanies the scrofulous disease, "except in a very few instances, and in the most advanced stage of the disease, when a portion of the ulcerated bone has died, and having exfoliated, so as to be loose in the cavity of the joint, irritates the parts with which it is in contact, and thus becomes a source of constant torment." (p. 256.)]
